EDITORIAL.

THE alumni of the Massachusetts Institute of Technology have collected a fund of $411,000 for current expenses of the Institute during the next five years. Eleven hundred men subscribed. This is the sort of spirit that makes a great college; the Massachusetts Institute of Technology deserves to prosper, not only in money, but in the reputation that money does not buy. There is an effective contrast between this instance of a technical institution financed by the many gifts of its own past students, and that of other places supported by the lavish donations of successful sandbaggers. Money itself may not be tainted, even when accumulated by dishonorable methods, but sentiment assuredly is more delicate; the enthusiasm of a graduate for his own place is worth more than the patronage of a pirate or the benevolence of a buccaneer.

IN a recent issue, referring to the Butte vendetta, we expressed pleasure at the cessation of litigation by the consolidation of warring interests, and we referred to Mr. Heinze's peculiar tactics as having followed in the wake of the earlier methods of Marcus Daly. This has been interpreted, by some of our friends, as meaning that Daly stole his neighbor's ore, which was not meant. We did mean to say that the lack of honor and disreputable practices that have disgraced Montana during the last ten years were not all of Mr. Heinze's doing, but that they grew naturally out of the low standards established at an earlier date.

MORTARS built to allow multiple discharge have been tried at many localities where stamp-milling is practiced. The article by Mr. Algernon Del Mar will be found to give a straightforward account of experiments made with batteries of this type. The author proves conclusively that the increased capacity to be secured by the use of multiple-discharge mortars is won at the expense of good extraction, for the gold is not allowed to remain in the battery long enough to be arrested by the mercury. It is for this reason that the steam-stamp, in vogue throughout the copper mines of Lake Superior, was a failure when imported into South Dakota. All those who take an intelligent interest in the process of the stamp-mill, know, or ought to know, that as a metallurgical device the stamp-mill is valuable chiefly because it combines in one operation the crushing of the ore and the extraction of the gold; neither as a machine for pulverizing quartz nor as a device for amalgamating gold is the stamp-mill all that it should be. When the stamps are used with the intention of crushing ore rapidly and uniformly, they are better replaced by rolls, Huntington and Chilean mills, etc.; so also when the mortar is devoted chiefly to the saving of gold, it will be found to be a crude extractor of the metal as compared to cyanidation or chlorination. The best results—that is, the largest profit per ton—can be obtained with the stamp-mill when it is applied to a simple gold-bearing quartz ore in such a manner that the rapidity of crushing is not sacrificed to, nor hindered by, the completeness of extraction. This economic ratio between the two factors requires the good sense of an experienced millman.

John Stanton.

It is a melancholy pleasure to pay the tribute of honor to a good man who dies in ripe old age after a career of exceptional usefulness. Sad enough it is to know that John Stanton has left the ranks of those that make industry noble, but stimulating to useful endeavor is the recollection of his cheery presence, kindly way and irreproachable integrity. He was born in 1830 at Bristol, England, and died on February 23, so that he had passed the allotted three score years and ten. From active work as engineer at his father's iron mines in Pennsylvania, he went to the copper regions of Tennessee, and when these were confiscated by the Confederate government, during the Civil War, he went first to Colorado, where he was associated with A. N. Rogers in the management of the old Gregory-Bobtail mines at Central City, and gave employment, among others, to W. A. Clark. Subsequently he moved to Lake Superior, where for forty years he was a notable figure. He organized the Atlantic, the Wolverine, the Winona, and Mohawk mining companies, he re-organized the Baltic, Michigan and Centennial, he was an important factor in the Copper Range consolidation and in the Michigan smelter. As agent for the various companies mentioned and as director of the Granby Mining Company he was a leader in the copper business. For a time he was the statistician for the copper producers of the United States, until the Amalgamated withdrew from the association. But to the mining industry even these important business achievements were of less value than the spirit of honesty and fair dealing that he exhibited, acting with other good men in making mining a clean pursuit as well as a highly remunerative speculation. In these days of shifting codes of morality and smart dishonesty, a man like John Stanton stood up like a bit of firm rock in a creeping morass. He was able to show that one could be clever yet straight, forceful and yet sincere, an outspoken critic and yet a true friend. All honor to his memory.

DAILY papers should be careful in making editorial comment on matters relating to technical science. Our neighbor *The Call* recently had some funny things to say on electric smelting, particularly in regard to the investigations made some time ago by Dr. Herault, in behalf of the Canadian Government. The scientist of *The Call* said that "Dr. Herault produces steel immediately from the ore as in the bessemer process. Whether this is done without the use of spiegeleisen as a neutralizer is not stated. Of course, the electrical heat is pure, without sulphur or other fumes or gases that affect the quality of the metal. There seems to be no reason why all of this is not possible. We are accustomed to the use of heat generated by electricity in cooking, and if the same or higher degree of heat can be introduced and diffused in the cupola the thing is accomplished." No sooner said than done. But electro-cooking and electro-smelting bear the same ratio as basking in a California sunshine does to the alleged calcining processes that proceed with so little interruption in a region where water is scarce and the society indifferent.

Changes at Pachuca.

Telegraphic advices state that the Real del Monte mines, at Pachuca, have been transferred to the United States Smelting, Refining & Mining Company, of which corporation Mr. A. F. Holden is general manager. This transaction has been pending for three months; it was initiated by Mr. Bernard MacDonald, who resides at Guanajuato, and taken up by Mr. F. W. Baker, of the Venture Corporation, Ltd. Mr. George A. Schroter, of Denver, made the examination of the properties, and when his report proved favorable Mr. Holden, representing Messrs. Clark & Coolidge, of Boston, closed the deal, on February 15. It is an important event, for it marks the transfer of mines that have been continuously in operation since 1739; it also means the invasion of modern mining and financial methods into one of the historic silver districts of Mexico. Pachuca produces about 6,000,000 ounces of silver and 30,000 ounces of gold per annum, the total value of the yearly output being $4,500,000. From the time of the early Spanish conquerors, more than three hundred and fifty years ago, to this day, the mines of Pachuca have been productive, despite several interruptions due to recurrent revolutions. The lodes are generously wide and the ore is not difficult to treat, for it has given a satisfactory extraction by the *patio* process. During recent years the richest mineral has been sent to the smelters, in Germany and in Mexico itself; concentration by vanners has preceded the *patio* and there has been a tendency to break away from antiquated methods. It is likely that this departure will be emphasized now that the principal group of mines has passed into foreign hands, but we trust that the advisory engineers of the new owners will not make the vulgar mistake of under-rating the intelligence of the Spanish-Mexican management, and therefore that they will be careful in superseding well-tried practice by hasty innovation. The transfer of these mines is likely to stimulate enquiry into the best method of treating the silver ores and will cause interesting investigations to be made into the pumping and other practice underground. The result should be a gain in knowledge and an increase of interest in Mexico.

IT is announced that General William J. Palmer and Dr. William A. Bell, both of Colorado Springs, have given that beautiful tract of land known as Manitou Park to Colorado College, in order that a school of forestry may be founded. Manitou Park contains 15,000 acres of mountain and lake, forest and plain; it is at the foot of Pikes Peak and in

the watershed of several large streams. No better site could be chosen for such a purpose. It is a princely gift from two men who took a prominent and useful part in the early development of Colorado.

A BOREHOLE put down from the bottom of the Cinderella shaft, at Johannesburg, from a depth of 3,900 feet and at an angle of 45°, encountered the Main Reef at a point 113 feet deeper. Six feet of quartz assayed 20.56 dwt. per ton, the 15 inches nearest the foot-wall assaying 92.78 dwt. The vertical depth from surface is 3,980 feet. At a similar great depth, of 4,000 feet, the Jupiter mine has developed the Main Reef where it is five feet wide and assays 25 dwt., besides the South Reef which at the same horizon is 2½ feet wide, assaying 44 dwt. per ton. Our friends on the Rand need some encouragement in these, to them, gloomy days; therefore it is a pleasure to note discoveries which promise to extend the depth to which profitable mining may extend. But they are a long way from the 6,000 and 8,000 feet involved in the academic discussions of a few years ago. Mines have their limit. Even the Rand is mortal. Methuselah lived to a ripe age, but even he had to go the way of all living things. But the Rand is getting older and the cheerful inconsequence of former days has been toned down by the Chinese and the Liberals, so we refrain from further comment likely to hurt a sensitive organization.

Blast Furnace vs. Reverberatory.

The development of practice based upon the use of these two types of furnace has progressed, on independent lines, so that both continue to hold their own in the metallurgy of copper. There was a time when the blast furnace threatened, by the increase of its capacity and consequent cheapness of operation, to drive the old reverberatory off the field, but the work done by Mr. Richard Pearce at Argo and by Mr. E. P. Mathewson at Anaconda proved conclusively that one type of furnace as much as the other was capable of the enlargement needed for large-scale operations. Of late the erection of new copper smelters has led to active investigation of the question by metallurgical engineers, as to the relativemerits of the two kinds of furnace, so that there ought to be plenty of data available for a useful public discussion. To start it, Mr. James W. Neill has prepared a set of twelve questions, which we publish in the hope that those metallurgists who are experts in the art of copper smelting will reply to them, emphasizing the particular points in which each man has had special experience.

There is no better way of getting at the essential features of any mining or metallurgical method than by instituting comparisons, for these bring out the facts, as a picture emerges from the darkness of a photographic plate when immersed in the developing liquid. We get a clear image of our ideas, discarding the accidental and emphasizing the basic principles that underlie every technical practice that has undergone logical growth.

Those who view smelting operations with that absence of prejudice which is only compatible with lack of knowledge, are to be forgiven if they regard the difference between blast furnace and reverberatory practice much as amateur artists who choose to work in oils in preference to sketching in water colors, because they think that any errors made in oils can be rectified by painting over the first attempt, while with the use of water colors it is recognized that any such botching will kill the purity of tone essential to a successful picture. The reverberatory is the pioneer device of the smelting man; the method it embodies is a sweating process, the germ of all elementary metallurgy, while the blast furnace, on the other hand, appeals to the mechanical engineer among metallurgists. If there is any trouble in the shaft furnace, either by reason of a badly proportioned charge or a refractory ore, it is possible, by elevating the temperature or modifying the feeding, to tide over the trouble. As the heat is applied from below and as oxygen is supplied through apertures—the tuyeres—that are under control, the conditions within the furnace can be changed without great difficulty. In the reverberatory, the heat is deflected from above—for that is what the word 'reverberatory' signifies—necessarily giving a low efficiency per heat-unit applied. By reason of the method of application, a great portion of the heat is wasted; this has been overcome to a large extent by the installation of boilers, placed in the flue, thereby intercepting the gases otherwise wasted, and generating up to 500 h.p. of steam in the larger and more modern reverberatory plants. Of late years, of course, the succession of hoppers that used to adorn the roof of a long reverberatory have become notably absent and the old ideas of keeping the hearth cool, removing all the matte and worrying the slag to the skimming-door have been discarded for tremendously long hearths, the retention of a constant balance of matte, the feeding of the charge only at the bridge-wall and an effort to secure a practically continuous exit of slag, so that the smelting operation proceeds uninterruptedly. All this is involved in the work done in the big furnaces at Argo and Anaconda, such as those described on another page by Mr. L. S. Austin, professor of metallurgy in the Michigan College of Mines. While blast furnaces have grown from dimensions at the tuyeres of 36 inches circular (with about 25-ton capacity per 24-hour day) to 58 inches wide by 52 feet long (smelting from 1,500 to 1,800 tons per day), the reverberatory has been enlarged from, say, 9 by 14 feet on the hearth (with a capacity of 10 or 12 tons) to 19 feet wide by 117 feet long (treating 275 tons). The hand of progress has quickened both, and in each case there has been a recognition of modern needs, exemplified in all our mining and metallurgical methods, of reducing the cost by the handling of a big tonnage. The chemical principles have undergone no revolution, beyond the recognition of the fuel value of pyrite, the ingenuity of the modern smelter superintendent having been directed chiefly to the mechanical problems, to elevating the ore to the feed-hole, to dumping devices, to the economical removal of the slag, and the manipulation of matte in converters, not forgetting the briquetting of fine ore before smelting.

This treatment of the fine is, after all, the chief problem today. Local conditions will modify the practice, of course, but, in the main, lump ore rich in sulphur will go to the blast furnace, while the fine, such as concentrate, will be fed to the reverberatory, particularly where oil is the cheapest fuel, as in California; or where pulverized coal is to be used, as in Utah. The old debate as to which furnace gives the higher slag will be revived, and it will be profitable only if actual results can be accurately quoted. The use of an auxiliary reverberatory furnace, with the addition of fine pyrite, to lessen the copper losses in the slag, is worthy of mention. The practice of water-cooling of jackets for the blast furnace is undergoing striking development. Many of the low-grade copper ores can be concentrated economically by milling before smelting; although the great capacity of the large blast furnace enables it to compete with water concentration on account of the greater saving made by fire as compared to water-concentration; so that the question is raised whether it is not cheaper to buy flux for refractory ores and secure a greater extraction than to concentrate with water and obtain an easier smelting mixture at the expense of high slime-losses and the many evils incidental to water concentration. This is done by crushing wet, sizing, and then separating the valuable mineral. In that case it becomes imperative to reduce the lump ore to fine, for without such reduction, concentration is impracticable; and yet, after it is thus concentrated, it must be re-consolidated before it is fit for the blast furnace. Here the reverberatory will score, until the blast furnace can be made to treat fine stuff by controlling and intensifying the heat at the tuyere zone. These and other problems are before the copper metallurgist; he has achieved much during the last two or three years; he can do more. Ten years ago the idea of smelting for a dollar per ton and mining for $1.10 per ton would have been scouted as impossible. Yet this has been done at the Granby mines, with an exceptionally favorable ore and exceptionally well-applied skill. In Tennessee, with low-priced labor and fuel, they smelt a copper-bearing pyrrhotite for $1.30 per ton. Such results are enough to stimulate interest and to promote healthy rivalry. Further improvement is only possible by comparing conditions and exchanging experience. Our columns are intended for this purpose, and we present the twelve questions as a text for vigorous discussion.

By the Way.

In our last issue we quoted, in this column, from an address by Mr. Martin A. Knapp, delivered before the American Association for the Advancement of Science. Mr. Knapp said much that was interesting and we do not apologize for giving our readers a further excerpt from his address:

The primitive man traveled on foot and moved his scanty belongings by carrying them in his arms or on his back. Even the rude vehicles and water-craft which he eventually learned to construct were propelled by his own muscle, and we can only guess how long it was before he obtained any other motive power for the transfer of his person or his property. In every way his life was meager and isolated, for he had not acquired the art of writing, and intercourse with his fellows was confined to ordinary speech. Outside the family to which he belonged, or the tribe with which he gathered, he had no community of interest, felt no friendship and desired no alliance. His associations were as limited as his means of conveyance.

In a later but still very remote period there came a great increase of motive power by the subjugation of animals, and their employment for transportation on land, and by the use of sails and rudders which multiplied many times the efficiency of water carriage. When these two results were secured, man had added to his own bodily powers the superior strength of beasts of burden and the enormous energy derived from the winds of heaven. This was an immense advance and marked the beginning of that wonderful civilization which slowly followed. The animal kingdom was brought into service for the various functions of land distribution, and the ship which could be sailed and guided made every waterway subservient to man's requirements. Early in this period also he learned to express his ideas by symbols or written words, and thus was enabled to transmit his thoughts by the same agencies that transported his possessions.

This leads to a fact of history which seems to me not merely significant, but profoundly impressive. With the subjection of animals and the use of wind-propelled vessels, both of which achievements reached a high degree of perfection in the unknown past, the means of transportation, broadly speaking, remained unchanged and unaugmented until almost down to the present time. Long before other agencies of conveyance were dreamed of, while ox and horse, oar and sail, were the only means of transport, the race had occupied most of the habitable globe and reached high levels of national greatness. Strong governments were established, vast populations engaged in various pursuits, and opulent cities crowded with every luxury. The institutions of society had acquired strength and permanence, the arts of leisure and refinement had approached the limits of perfection, and inductive science had laid firm grasp on the secrets of nature. Great inventions and discoveries had widened the fields of activity, furnished the means and incentive for multiplied vocations, and opened up in every direction alluring vistas of advancement. In a word, there was the developed and splendid civilization of only little more than threescore years ago, before any new or different motive power was utilized for production or distribution.

To my mind it is a matter of fascinating import that the long procession of progress down to the century just ended was conditioned by and dependent upon agencies of transportation which were themselves essentially unprogressive and incapable of important betterment. Reduced to the forms in ordinary use, there were at the last as at the first the beast of burden on land and the oar and sail on water. Yet thus hampered and restricted in the means of transportation, which is the basis of all development, there was built up in the long process of years the varied and advanced civilization which the last century inherited.

Then all at once, as it were, into and through this social and industrial structure, so highly organized, so complex in character, so vast in its ramifications, yet so adjusted and adapted to the fixed limitations of animal power, was thrust the new mode of conveyance by mechanical force, the sudden wonder of transportation by steam. The advent of this new and marvelous agency was the greatest and most transforming event in the history of mankind. It wrought an immediate and radical change in the elemental need of society, the means of distribution. The primary function was altered both in essence and in relations. The conditions of commercial intercourse were abruptly and fundamentally altered, and a veritable new world of energy and opportunity invited the conquest of the race.

No other triumph over the forces of nature compares with this in its influence upon human environment. It has directly and powerfully affected the direction and volume of commercial currents, the location and movements of population, the occupations and pursuits in which the masses of men are engaged, the division of labor, the conditions under which wealth is accumulated, the social and industrial habits of the world, all the surroundings and characteristics of the associated life of today. The world has seen no change so sudden and so amazing.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and to give information dealing with the practice of mining, milling and smelting.

THE friction of water in pipes increases as the square of the velocity of the water.

SMELTING is a universal metallurgical method, but is not always applicable, for commercial reasons.

GREASY MACHINERY may be quickly cleaned by directing against it a jet of steam from the boiler.

HOISTING cables in mines should have a factor of at least 5, and if to be run rapidly, not less than 7.

STIFF ropes for the transmission of power are not satisfactory as they require a greater amount of power to operate them.

A FRACTIONAL CLAIM requires the same amount of work annually as a full claim, no matter how small the fraction may be.

COARSE GOLD has been picked up on the surface at a number of localities in southern California and in Arizona and Nevada.

VERY LITTLE successful hydraulicking has been done in the Black Hills of South Dakota. It has mostly been on a limited scale.

THE United States of Colombia, S. A., is said to have produced more than $800,000,000 in gold, and Bolivia about $200,000,000.

THE symptoms of lead poisoning are not an increase in weight of the afflicted party (due to metal absorbed), but quite the contrary.

A HIGHER percentage of power is transmitted by long belts than by short ones of the same width and ply and running at the same speed.

ONE ton of gravel in the bank is usually figured at about 18 cu. ft. to the ton, though gravel is generally estimated by the cubic yard.

THE power required to effectively drive crushing rolls depends upon their speed and diameter and upon the character of material being crushed.

NO WATER for boiler use is superior to rain water. Nearly all water from the ground contains mineral salts in solution, which will deposit scale in the boiler.

THE first dividend of the Calumet & Hecla copper mine, at Houghton, Mich., was paid August, 1870, since which date it has paid over $92,000,000 in dividends.

A BELT concentrator requires generally from 200 to 300 gallons of water per hour. Large machines require more than smaller ones and heavy ores more than light.

IT is not permitted to cut timber on the public lands of the United States for sale to others. On the mineral lands timber may be cut for mine use, but not for sale.

THE quantity of water which may be introduced into a mortar of a stamp-mill must be determined by the character of the ore and the facility with which it amalgamates.

IT was claimed at one time that the New Idria quicksilver mine in San Benito county, Cal., could produce mercury cheaper than any other mine in the United States.

GRAPHITE is very useful about the iron foundry. Not a casting is made, large or small, where graphite is not employed to prevent the casting adhering to the mould of sand.

THE gold-bearing gravel deposits along the valley of the Rio Grande, in New Mexico, are said to be from 50 to over 600 ft. in depth. They are often cemented, and miles from water.

MANY miners believe that the veins in their claims were injected from below like dike rocks, and this idea is probably responsible for the term 'blowout,' applied to the croppings of a vein.

MOLTEN SLAG from blast furnaces, when treated with a jet of steam, becomes a finely fibrous, silky mass, known as mineral wood. It is used as a non-conductor of heat, on boilers, pipes, etc.

CLAYS which resist the heat of ordinary furnaces are called refractory. Many volcanic rocks, chiefly tuffs, resist heat admirably and these are therefore suitable for furnace linings and the like.

THE stockholders' liability in California makes each share holder in a corporation responsible to each creditor of the company in exact proportion to his holdings of the capital stock of the company.

HEAVY SURFACE INFLUX of water into a shaft may be kept out either by driving sheet-piling or by constructing a double line of close lagging with clay packed between, forming a 'coffer-dam' structure.

ZINC is not suitable for use in contact with copper, lead or iron, owing to the strong galvanic action taking place when zinc comes in contact with either of these metals, particularly in the presence of moisture.

BROKEN ROCK always occupies a larger space than it did in place, but fine material, sand, loam and gravel require less space than when undisturbed in the earth. This shrinkage amounts to 5 to 15%, with different materials.

MOST millmen prefer to save all the gold possible inside the mortar. Outside amalgamation is mostly practiced on low-grade ores, where large capacity is desirable. Feeding 'quick' by guess has long since become obsolete.

IN arranging a metallurgical plant, the engineer must look into the future requirements of the property, and not only arrange the plant so that gravity may be taken advantage of, but also keep in mind future possibilities and design accordingly.

TIN has a low melting point—446° F.—but when exposed for a long time to extremely low temperature it will be found covered with blisters, and it becomes very brittle, and has even been known to disintegrate. It also becomes brittle when heated.

IT depends whether it is desirable to break the rock in the quarry coarse or fine whether high-grade or low-grade powder be used. Powder containing a high percentage of nitro-glycerine will break rocks into smaller pieces than the low-grade powders.

IT has been claimed that Mexicans washed placer gold from the gulches about Newhall, in San Francisquito canyon, and in the Castec region, in western Los Angeles county, Cal., years prior to the discovery of gold at Sutter's mill, in El Dorado county, in 1848.

IN forging rock-drill bits those for medium hard rock should have sharp chisel bits. As the hardness of the rock increases, the angle of the bit may be made more blunt, and the cutting edge shaped from a straight line to a curve, to prevent the corners being chipped off.

THERE is no standing Government reward for the discovery of tin in the United States, nor has there ever been, though such appears to have been the impression for many years. The greatest incentive to the discovery of tin is its present price, about 36c. per pound.

IT is said 'mining is a gamble,' which in a certain sense is true. All business enterprises are to an extent gambles—that is, all possess those elements of uncertainty which make business attractive. No business is more honorable, nor offers better opportunities than legitimate mining.

BEAUTIFUL vein structure and wall rocks the same as this or that great mine are not indicative of as great value, or, in fact, any value at all. Each mine must stand on its own individual merit, and geological conditions similar to those elsewhere are not trustworthy evidence of a valuable mine.

THE auriferous quartz veins of the California gold belt contain from 1% to 2% sulphides which are worth from $20 to $200 per ton, averaging about $70. There are exceptions, particularly in the veins in granite, where the percentage of sulphides may be higher, and sometimes the values also.

ORES, which are refractory when treated alone, if sent to smelters are mixed with numerous other ores, together with fluxes, the refractory ore forming only a small percentage of the whole mixture, and as a result offers little difficulty to treatment. This is an advantage other methods of reduction do not possess.

TEMPERING of steel tools is an art which one may acquire under a competent instructor. There is considerable difference in the character of steel made by various manufacturers. The drill-sharpener must become acquainted with each kind of steel and its peculiarities before he can do the most satisfactory work.

THERE is gold in the glacial lake bed deposits covering a large portion of the Leadville district, but they have not been found sufficiently rich in the metal to pay. The early placers derived their gold more directly from the gold-bearing igneous rocks lying on the range east of the city, and not from the gravels of the glacial age.

IT has been claimed that stone mortars, supposed to have been used by a prehistoric race, have been found in some of the ancient river channels of California. These reports have not been verified sufficiently to give the statements absolute authority. It is believed that some of the so-called stone mortars are merely imitative shapes accidentally produced by the unequal wearing away of a boulder in the stream.

THE portable firebox-boiler, sometimes called locomotive boiler, is convenient, but is extravagant of fuel. All such boilers should be provided with a damper in the stack, and, unless for only short, temporary use, a water-heater as well. The return-flue boiler is far more economical in operation, though more expensive in first cost.

THE locality producing the largest mass of native copper is in dispute. Some very large masses have been found in the Lake Superior mines and also in southeastern Arizona. Ordinarily the mine owner prefers small disseminated grains to great masses, as the latter are expensive to extract from the mine and frequently yield no profit.

TIMBERS are sometimes secured together by means of drift bolts. This is an iron rod with a chisel or four-sided point, which is driven into an augur hole bored in the timber, but of somewhat smaller diameter than the bolt. Smooth, round iron is better for this purpose than square bars or that having jagged edges which tear the wood in driving.

THE first to introduce winding and dry washing for gold in the United States were the Mexicans and Indians in the Southwestern mining regions; but white men soon invented various mechanical devices for this purpose. These machines give a larger capacity and generally better results than are obtainable by the primitive hand methods practiced by the Mexicans and Indians.

NEVER rush a missed hole—give it plenty of time, and all night is not too long sometimes. The missed hole is one of the greatest menaces to the miner. When safe to examine the hole, carefully withdraw the tamping down to the powder, insert another primer, and after re-tamping the hole fire it again. Should it go, the chances are in favor of all the powder in the hole being exploded.

THE price of cordwood usually varies according to the wages of the country where it is cut, and with the cost of hauling it to the market. Wood may be worth only $5 a cord where wages are $3 per day, and in another locality, where woodchopper's wages are but $2, the wood may cost $6 or more delivered, on account of the long distance it has to be hauled. The same applies to mine timbers.

CARRYING stopes to the surface from the upper levels of a new mine is bad practice, particularly in a wet country, as it will result in allowing much storm water and surface drainage to run into the mine, which is something to be avoided, and particularly where there is no drainage outlet, such as a tunnel below. The surface works of numerous mines have caved from the cause here referred to.

THE wear of shoes and dies in the battery varies greatly, partly with the character of the ore, and partly with the material from which shoes and dies are made. Chrome and manganese steel shoes and dies are less affected than those of iron. The cost is from 0.5 cent to 2 cents per ton of ore crushed. Quartz ores naturally are more destructive of shoes and dies than the softer slaty ores.

WHERE a ditch or road existed prior to a mining location covering it, the ditch or road may be maintained. The question of abandonment of a ditch or a mining location is partly decided by the intention of the proprietor; but his intention, to a great extent, may be evidenced by his compliance with the legal requirements. Neglect to comply with the demands of law will defeat the locator of the claim, even though he may say he had no intention of abandoning the location.

THE Supreme Court of the United States has decidde that the several States may make laws governing the location and holding of mining claims, which are not in conflict with the Federal laws. A State or territorial legislature may therefore enact laws which require more of the locator of a mining claim than is required by the Federal law. These additional requirements are in the way of performing certain work within limited time (60 to 90 days) as a part of the act of location.

THE statement that the copper ore in any particular locality resembles that of Butte, Montana, has no particular significance, as copper ores are characteristic everywhere. Green or blue carbonate looks much the same wherever found. Chalcopyrite, and bornite and chalcocite are immediately recognized by those familiar with sulphide copper ores, whether at Butte, in Chile, in the heart of Africa or any other place on earth. The associated gangue minerals may be far more characteristic of a locality.

SNOWSLIDES annually do much damage in Colorado, and loss of life is not of infrequent occurrence from them. Many ingenious arrangements are made to protect mine buildings from destruction by snow. This is done by building under the protection of jutting rocks, or by cutting out a grade in the solid rock itself. Some of the mine buildings are actually suspended from the cliffs. In the event of a snowslide, the great rushing mass of snow slips over the rocks, but does not reach the building below. At most of the best mines operations are continued throughout the long winter at altitudes varying between 8,000 and 12,000 feet.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

BLAST FURNACE *vs.* REVERBERATORY.

The Editor:

Sir—Progress in the art of smelting copper ores has been most rapid in the last two or three years; the achievement has been largely in the line of increase in the size of furnaces—both blast and reverberatory—and consequent decrease in costs of operation. With this increased production per furnace the improved handling of materials has had to keep pace, and the mechanical engineer has proved an efficient partner to the metallurgist. The question as to the relative merits of the blast furnace versus the reverberatory is coming into prominence by reason of the enormous increase in the tonnage smelted by the latter, and its better fuel ratio, as well as the possibilities in the way of steam generation. Naturally, the choice of the style of furnace must depend on the size of the ore-particles, fine going to the reverberatory, and coarse material to the blast furnace. Thus the smelting of concentrate has naturally fallen to the reverberatory, and with this also the smelting of flue-dust and such of the fine as can be screened from the crude ore. Is this division justified by the results? There are, among metallurgists, partisans of each type of furnace, with decided ideas on the subject Could you not start, through your columns, a discussion of this important matter in somewhat the same way as you treated the question of pyrite smelting? I would like to suggest the following questions as among those to be asked, though I am, of course, aware that the financial results of many smelting works cannot reasonably be given to the public, except in a general way:

QUESTIONS—BLAST FURNACE *vs.* REVERBERATORY.

1. On what should the choice of furnace type be principally based? Character of the ore, fuel, fluxes, building materials?
2. What are the comparative costs per ton of daily capacity of each type of furnace? In the case of the reverberatory, this cost should include the expense of the necessary roasting plant.
3. What is the comparative space requirement for an equal tonnage?
4. What is the comparative cost of mechanical equipment for equal tonnages?
5. What are the comparative costs of power, labor, fuel and repairs?
6. What are the comparative amounts of capital tied up in furnaces of each type, and how does this affect the cost per ton of daily capacity or of output?
7. What are the limiting necessities in the way of fuels for each type?
8. What are the comparative losses in slag, dust, or middle products?
9. What are the defining limits of each type in regard to slag composition?
10. How do these differences of slag figure out in financial margins per ton smelted?
11. What method of charging do you advocate for a copper furnace (assuming the atmosphere to be oxidizing)?
12. Would you bind, in some manner, all fines for use in the blast furnace? Incidentally, what are the difficulties of treating fine ore in the blast furnace?

JAS. W. NEILL.

San Francisco, January 11, 1906.

BLAST FURNACE *vs.* REVERBERATORY.

The Editor:

Sir—Herewith I beg to submit some data showing the assays and analyses of reverberatory and blast-furnace slags made in one of the smelting works at Butte during the same relative periods, and thus affording a fair comparison of the work done by the two types of furnace.

The figures given in the first table are actual averages, made up from weekly averages. These were made by saving equal parts of all daily samples from all furnaces, and mixing them. Copper determinations were made on these weekly samples by electrolytic methods; on the daily samples color tests were made. The slag samples from the reverberatory furnaces were taken from the stream as it overflowed from the first or settling slag-pot; those from the blast furnaces were taken from the stream overflowing from the settlers. The shells from the first pots of the reverberatory were saved, dumped on the surface and sorted, any 'prills' or foul bottoms being returned to the works for smelting in the blast furnaces.

The second table shows the constitution of these slag-shells as taken from the first reverberatory slag-pots; all the shells from one day's work of all the furnaces were saved, dumped, sorted, and the different materials were sent through the sampling mill. Special interest attaches to the assay of the tops, for these contained much undecomposed quartz, drawn from the furnace in the shape of 'floaters.' This material is supposed to be thoroughly liquated of all the metals, and the ability to get rid of such silica in this manner is one of the boasted advantages of the reverberatory system. Later practice does not make so many of these 'floaters.'

The next figures show the actual contents of the shells of all first pots of reverberatory slag for one day, without any sorting; all of them were sampled in a mill. This material would probably pay for re-treatment in the blast furnaces, when not already burdened with converter slag, etc.

To check the slag usually poured to waste, that is, the overflow from the first pot of the reverberatory, a clean ladle was substituted for the second slag-pot, all the slag of one skimming was caught in this and then poured into cast-iron moulds, which were sent through the sampling mill. The assays and analysis of this material are given in the last row of figures, and a comparison is made with the results of the daily assays for the same day. Comment seems unnecessary. The slags from the blast furnaces were always dumped without saving shells. Tests on larger quantities of this material were not made.

The marked difference in the general composition of the slags for the two general periods is accounted for by the fact that the former practice of smelting mine-fine was largely discontinued, and this material was sent to the concentrating mill instead, more concentrate being produced, and a larger proportion of it being used on the charge. The differences in the assay-values on the reverberatory slag are, however, not alone due to the increase of iron content in the slag, but also to the method of feeding the ore in smaller and more frequent charges, these being dumped close to the bridge, thus transforming the back of the furnace into a settler. This is the Anaconda method, and on their large furnace it should result in yielding a cleaner slag.

I will leave to each metallurgist the task of figuring for himself the value of the difference in metal values between the two types of slag given above, as each man has his own notions as to 'margins' and prices to be used in such computations, but I think it is pretty safe to predict that it will not be found to be less than $1 per ton of slag, in favor of the blast furnace. The average of the ores at Butte is about 65% silica and 15% iron; the loss in concentration is not far from 20% of the metals, the concentrate produced being the only iron flux; limestone costs about $1.10; it will, therefore, be seen easily that the value of the iron as a flux is used to much better advantage in the blast furnaces than in the reverberatories, and this should be credited to this type of furnace-slag. The question as to whether it would not pay better to briquette all concentrate and fine, and put them into the blast furnaces, rather than submit to such losses, is one not readily answered.

MINING ENGINEERS AND GEOLOGISTS.

The Editor:

Sir—It is unseemly for 'mining geologists' and 'mining engineers' to dispute concerning trespass from either side upon contiguous or overlapping territory. May it not be that each is worse hurt by his own excursions than by his confrere's incursions, over the border line? I am tempted to draw upon personal experience for illustrations, trusting that nothing of controversial value will thereby inure to either side.

Case No. 1.—A mine, or group of mines, involving millions of dollars, was examined by several geologists and engineers, and reported upon unfavorably by some, favorably by others. The geologists who were not engineers all reported adversely, mainly because the geologic structure was complicated and the dynamic effects of successive uplifts were difficult to estimate. The engineers were not all favorable, those reporting adversely basing conclusions wholly upon the average of all mine samples and treating the property as a mine of ordinary type. The favorable reports were made by engineers who considered the mine by itself as a problem, with due reference to its individual geologic features, after *measuring* dynamic relations of each disturbance. The history of the mines has fully justified the favorable reports. But, in working it, geologic relations being too much disregarded, much useless and unprofitable excavation was undertaken, unnecessarily reducing the realizable profits.

Case No. 2.—A mine which yielded profitable ore was operated by an engineer who lacked geologic training. After much systematic development, admirably executed, the ore gave out and could not be regained. Upon the advice of a mining geologist, not trained as an engineer, the original operator (engineer) opened ground in an unworked direction with very satisfactory results.

Case No. 3.—Mine worked in good fashion by an engineer, not a geologist. Misinterpreting geologic conditions, the workings left the vein and mine was abandoned. Afterward the geology was carefully put upon the mine maps by a competent person, and the error in working thereby detected. The mine was then worked successfully.

Case No. 4.—Mine located and worked in accordance with results of geologic study, following structural lines. Results disastrous. An engineer reopened and successfully followed the orebody by systematic exploration.

The necessity, if such exist, for any controversy as to the respective merits of geologists and engineers in passing judgment upon mining enterprises, arises absolutely and entirely from the nature of the problems involved. The adaptability of either as professional practitioners is altogether a personal side-issue. The difficulty of deciding which should be consulted in any given case is inherent in the business of mining, not in any hard and fast boundaries of the professions. However, there may be some danger in the personal factor, if it inhibit the admission of ignorance, upon one side or the other, of what is necessary to form a dependable commercial opinion.

Certainly the mining geologist, *as such*, can lay no just claim to understanding of the intricate and complicated problems which it is the particular province of the engineer to solve in terms of profit and loss—the critical test of all mining operations.

On the other hand, the well-equipped mining engineer, *strictly as such*, must always base his operations upon certain knowledge of geologic facts. And it is evident enough that employers of engineers have heretofore usually expected this necessary information to be acquired by the engineer himself. If the profession of the practical economic geologist has at last become virile enough to assert its rights to be recognized as a business factor, right royally may mining engineers welcome its votaries as indispensable allies.

But, unfortunately, there are so-called 'mining geologists' of the highest reputation and of undoubted abilities, who persist in demanding recognition as practical business guides in mining enterprises without the training and experience necessary to qualify them. We frequently see in prospectuses of mining companies that such or such an "eminent geologist" or "celebrated mining engineer" has reported favorably upon the property in question. None need be deceived by such statements, for it is easy to demand a view of the actual report.

My own practice is invariably to deny that any man has real standing as an engineer who will sign a report in such vague terms, with no details from which a brother engineer can draw safe conclusions. The geologist may produce abundant evidence in his reports of ability to read the structural record and he may have a reputation beyond question, and still be a very unsafe guide in the matter of investment. It is a sure mark of incompetence in an engineer to write that "the mine ought to pay well if properly managed," leaving the reasons for such belief and the methods of proper management unstated. But this is exactly what has become the stock in trade for conclusions in geological reports. The facts of geology are of vastly more importance than some engineers appear to realize: but, if they present good foundation for a business enterprise, they must serve as an introduction to the vital discussion of ways and means of converting capital into dividends and amortization funds.

Which all goes to say that any attempt to make controversy out of the right relations of geologists and engineers will carry one around the circumference of a circle, ending where it begins.

Many mines have failed mainly through lack of close attention to accounts. But this is not saying that, with favorable resources, the company which employs a competent accountant will always be successful. Put 'geologist' in place of 'accountant' in the foregoing, and the statement holds good. Substitute 'engineer' for 'geologist,' the comparison fails. *Ergo*, what is gained by trying to subtract four loaves of bread from four pounds of meat.

THEO. B. COMSTOCK.

Los Angeles, February 24, 1906.

THE SURVEY AND THE TECHNICAL PRESS.

The Editor:

Sir — You state in your editorial of February 17 that one or two officers of the Survey attempted to control a Chicago mining paper.

This statement was made last summer in the daily press, and was satisfactorily replied to by the Director through the Associated Press. Recognizing the excellent standard of accuracy and fairness of the MINING AND SCIENTIFIC PRESS makes me call your attention to this reply and to add an absolute denial of any such attempt to bring the *Mining World* under the control of officers of the Survey, or to change its control in any way from the present owners.

I know that you will welcome this correction and be more than glad to convey it to your readers.

DAVID T. DAY.

Portland, February 19, 1906.

(We publish this without caring to make further comment.—EDITOR.)

THE BEST SHAPE FOR A SHAFT.

The Editor:

Sir—This certainly is a topic worthy of discussion. We have become so accustomed to the rectangular opening of two, three or more compartments that it is seldom the mine manager gives thought to the possibility that there may be better forms of shaft than the rectangular shaft of ordinary type. We all know there are other forms than that here referred to, but they are mostly in distant countries, and few American engineers have had experience with these large, circular, square and octagonal-shaped shafts, and comparatively few have ever seen them.

When deciding upon the shape and size of a prospective shaft, consideration must be given the cost and the maximum amount of ore, rock, etc., to be hoisted, and materials and men to be handled through it in any single day.

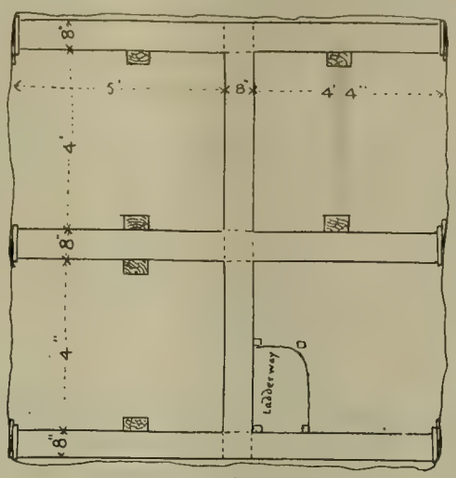
Occasionally a shaft of some sort has previously been sunk on the site of the proposed deep shaft, and it is desired, if practicable, to make use of this. Such was the case stated by Mr. R. H. Burrows as occurring at Guanajuato, in your issue of February 24. This old shaft is described as being 10 ft. square and 320 ft. deep, and sunk in "ground so hard that no wall-plates were necessary in the shaft." Certainly under such conditions it would be desirable to utilize the old shaft, as it would in any event mean a saving of at least $30 per foot in sinking and probably more —a matter in this instance of perhaps $10,000.

The shape of the shaft is important, and a decision on this point can only be safely reached with a knowledge of the ground through which the shaft must pass, which is usually impossible. In heavy or swelling ground no shaft is sunk with greater facility than the rectangular shaft of two, three or more compartments, and shafts of this type have been found to fulfil every essential requirement at many great mines. Openings of other shape have been sunk to a depth of 1,500 to 2,000 ft. and more, but their superiority over the plain rectangular shaft has, so far as I am aware, never been demonstrated, either as to first cost, adaptability for the work, or amount of rock that may be hoisted through them I confess I favor the rectangular shaft with a single line of compartments. This may be old-fashioned, but it is known to be satisfactory.

Mr. Burrows says it was desired to sink a shaft through which 1,000 tons might be hoisted daily, if necessary. A shaft such as suggested by him, namely, 5 by 16, would certainly be large enough to admit of this amount of rock being hoisted without difficulty. Two hoisting compartments, each 5 by 4.5 ft., will accommodate skips of five-ton capacity, if all the space available be utilized. There would be three compartments—the two hoisting sections, as described, separated by nine-inch dividers, to which are attached the guides, at least 4 by 6 in. This would leave the pump and manway compartment 5 ft. by 4 ft. 9 inches.

The manager's plan to enlarge the cutting to 10 by 16 ft. is ingenious, and at first glance seems feasible; but no provision is made for timbers to carry the guides, pump column, etc., which must be provided in any case. These supports must be of either timber or steel. Another thing apparently overlooked is the necessity of cutting double stations and ore pockets underground, and it also requires the installation and maintenance of two separate hoisting plants on the surface.

To place sprags, or dividers, in the shaft and to set them in exact alignment would in the end be quite



Sketch of Steel Structure for Shaft.

as expensive as timbers and far less satisfactory. On the whole, the 10-by-16-ft.-shaft idea as outlined has little to recommend it. It involves much unnecessary expense, is far larger than the demand requires and the plan should, in my opinion, be dismissed without further consideration.

It may be contended that a shaft of the dimensions stated (5 by 16 ft.) is not large enough for the hoisting of 1,000 tons per 24 hr. I believe it to be sufficiently large, not only for that amount, but for much more, if necessary. Assuming that the skips have a capacity of only four tons each, and the maximum winding speed to be 1,500 ft. per minute—a very moderate speed these days—or say that a round trip, including loading and discharge, can be made with each skip from the deepest level (2,300 ft.) in five minutes. This is 48 tons per hour for each skip and 96 tons for the two. Running steadily, 1,000 tons could be hoisted in about 10½ hours. Assuming that two hours are consumed in lowering and hoisting men alone, this makes only 30 minutes over 12 hours to do all the hoisting for the entire 24 hours, leaving 11 hr. 30 min. for repairs, oiling machinery, 'doping' the rope, handling materials, etc. I think I am placing this proposition on a very conservative basis, as at Kimberley they have found no difficulty in hoisting more than 4,000 tons through one rectangular shaft from a depth of about 1,500 ft., week in and week out—this being their daily performance, anything else being an exception.

In Volume XXX of *Trans.* A. I. M. E., p. 986, I find this note by Thos. H. Leggett, taken from the De Beers Con. Mine Co.'s eleventh annual report:

"At the De Beers mine on May 17, 1899, 9,261 loads of blue ground, equal to 7,409 tons of 2,000 lb. each, were hoisted from a depth of 1,200 ft. by one engine (working in two compartments) in 24 hours."

This hoisting was done from a single loading station, which is, of course, a great advantage; but it is evident that there should be no difficulty whatever in hoisting 1,000 tons from depths down to 2,300 ft. through a three-compartment shaft of the dimensions above described, working in two hoisting compartments, provided the engine be suited to this heavy duty. When greater capacity is demanded, it is always better to increase the load than the running speed.

Returning to the Mexican shaft, I do not approve of the offset suggested at 320 ft. in the shaft, and believe it would eventually be a most unsatisfactory arrangement. Bailing is in many cases more satisfactory than pumping after the shaft has reached its greatest depth, or, at least, a depth at which it is likely to remain for a long time. A large water-skip could be placed in the third compartment, or one of the rock-skips could be swung out of the shaft at the collar and a water-skip swung in. This can be quickly accomplished where the necessary provision is made for thus changing skips. With a 1,500-gal. water-skip, there should be no difficulty in hoisting 20,000 gal. per hour from a depth of 2,300 ft., and with proper hoisting equipment, much more than this can be handled by bailing.

On the Comstock lode, at Virginia City, the Foreman shaft was sunk in the form of an L. There were three compartments in a line, in the usual manner, with a large compartment at one end for pumps, etc. The experiment was not repeated. It was found that the unequal pressure on various portions of the shaft caused the timbers to rack badly, and repairs were frequent and costly. Where ground is heavy, the compartments had better be longer across the shaft and narrow, as this places the dividers closer together and the timbers are better able to withstand the thrust; but in cases where the ground is so firm that wall-plates may be dispensed with, the form of shaft may be that which suits the fancy best, though I still maintain that the three or four-compartment rectangular shaft has no superior. As to size of the compartments, that is another consideration. Where large amounts of timber and other supplies must be daily sent down into the mine, it is well to have one large compartment and separate engine for this work. It would be well to make this compartment so large that a trolley or flat car could be run onto the cage with the timbers lying flat upon it, instead of standing on end in the usual manner. This would save much time in handling of timbers.

The pump, or bailing compartment, also provided with separate hoist, might to advantage be placed between the two rock-hoisting compartments. Where cylindrical or cone-shaped winding drums are used, this arrangement will admit of the drums being so disposed that there will be less side draught to the rope on the sheave, due to the travel of the rope across the face of the winding drum. At many large shafts the pumps and pipes are handled by a separate and usually somewhat smaller engine. This is an advantage, and is economical, as it saves waste of power and wear of machinery.

If it is desired to utilize the 10-ft.-square shaft, this might be done by first dividing it into two compartments, one of which would be 5 by 10 ft. clear, and sub-dividing this into two compartments, each 4 by 5 ft., employing a light frame of steel I-beams. These would take up less room and probably be less expensive than the ordinary shaft sets of timber placed five feet from center to center, as the steel frame might be constructed 15 ft. from center to center. By this means two hoisting compartments could be obtained, and one compartment 4 ft. 4 in. by 10 ft. for manway, pumps, etc., and, if desired, the large compartment might be so arranged that a service cage could be operated at one end for handling men and materials, and the pump-column, air-pipes, wires, etc., placed at the other. This idea does not contemplate wall-plates, but does provide for ends and a divider, which, if supplied with square plates at the end of each section of steel, adjacent to the wall, could be tightly wedged. To these pieces could be attached the guides, bolted and riveted to the beams.

A steel center column would carry all of the several beams, five in all, which are wedged to the walls by blocking in the manner usual with butt-caps or sprags in stopes. The arrangement permits the stations to be cut on one side of the shaft—that nearer the hoisting compartments—and the winding machinery on the surface could all be placed on one side, that operating the service cage and handling the pumping equipment being between the shaft and the main winding engines. On this plan the shaft need not be enlarged, but continued to any desired depth, 10 ft. square. The accompanying sketch illustrates the contemplated division.

W. H. STORMS.

Recent Improvements at Anaconda.

Written for the MINING AND SCIENTIFIC PRESS by LEONARD S. AUSTIN.

In the MINING AND SCIENTIFIC PRESS, Vol. LXXXIV, page 202, in 1902 will be found a description of the plant of the above-named company, at that time just completed, and representing the most advanced practice of that day. The plant has remained, in its general features, much as then constructed, but its furnaces, both blast and reverberatory, have been enlarged so as to greatly increase the output.

Three years ago the plant came under the charge of Mr. E. P. Mathewson, upon whom devolved the work of bringing the organization up to its present condition of efficiency. This he brought about by measures looking to improvement in discipline, and to the harmonious working together of the different departments.

Then came up the question of larger and cheaper operating furnaces. The first to be considered were the reverberatory matting furnaces, already the largest known, with hearth dimensions of 20 by 50 ft. They were smelting 105 tons daily with a consumption of 27% of coal. Accordingly, one of the furnaces was lengthened out to 65 ft., and, with the encouragement thus afforded, to 85 ft., and, finally to 102 ft. length of hearth. The width was, however, not increased because of the thrust due to the weight of the roof. With this to go on, upward of $120,000 was spent in changing the 14 furnaces (each 20 by 50 ft.) to seven large ones, each 19 ft. wide, and varying in length from 102 up to 117 ft. This was done by throwing two furnaces with the intermediate space into one large one, so that the seven large furnaces had one-fourth more area than the smaller 14. As a result of these changes each large furnace now puts through 275 tons daily with a consumption of but 21% of coal, this item having been reduced to a cost of $1 per ton of charge. The fire boxes are 7 by 16 ft. in size in order to burn the large amount of coal per furnace, some 56 tons daily.

Washoe Plant, Anaconda, February, 1906.

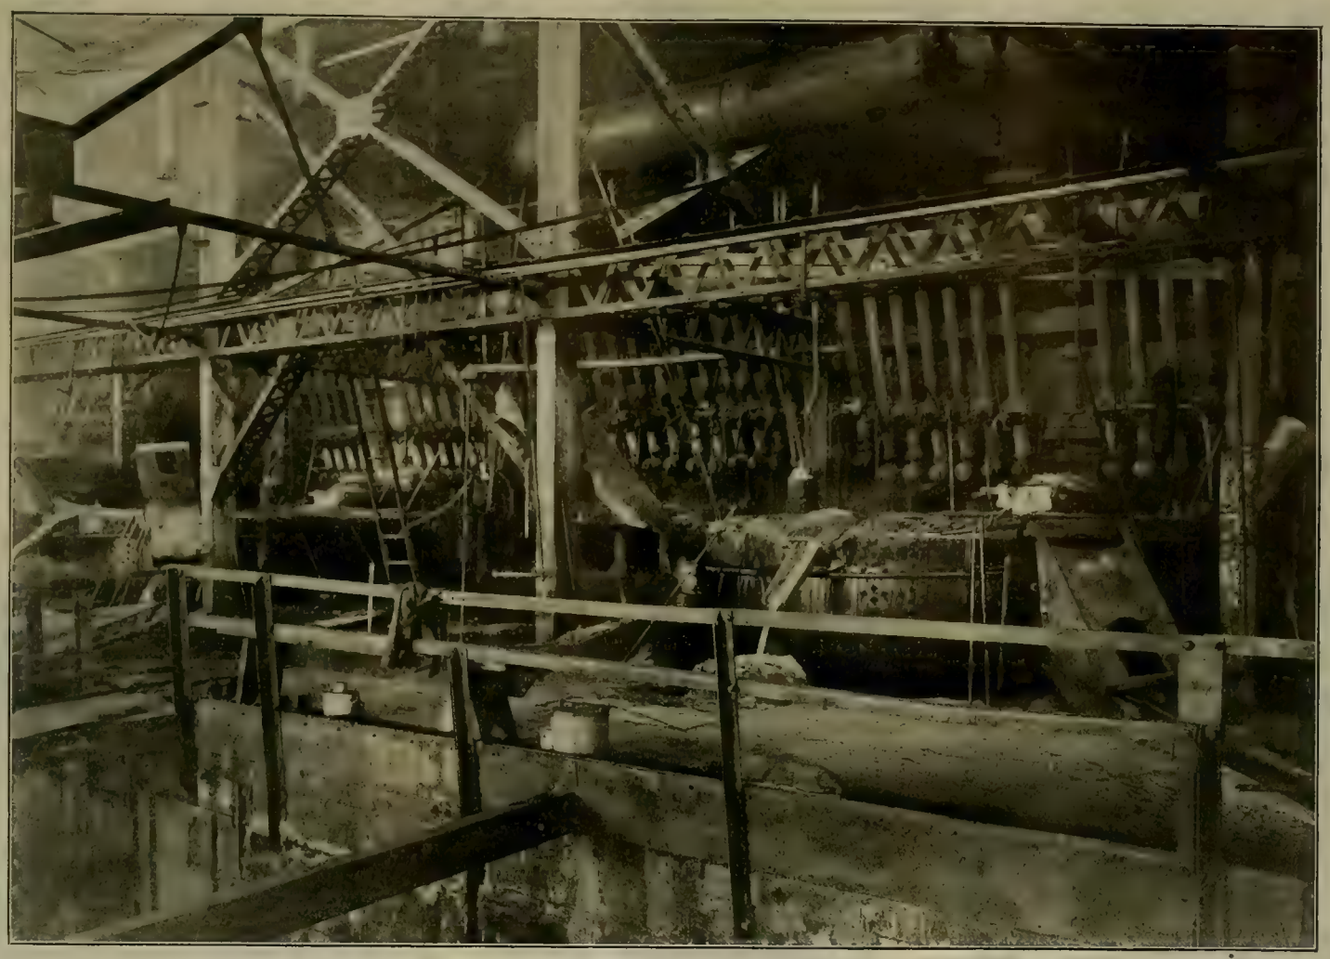
The next question to take up was the blast furnaces, seven in number, each 15 ft. long, 56 in. wide, with a capacity of 420 tons each daily. The changes at the reverberatory plant would naturally suggest the same idea of throwing two blast furnaces into one, but the question was, whether so long a furnace as 51 ft. would work, and whether so large a unit would not, with some mishap, cause a decrease of tonnage out of proportion to any advantages otherwise obtainable. To find out in advance, it was necessary to know if a jacket, needing repair, could be removed from existing furnaces without taking off the blast. Fortunately, the jacket gets crusted over, forming a shield against the fire so that the experiment was successful. Following this it was necessary to find out whether a part of the hearth, or of the furnace, could be cleaned out, while the rest kept on smelting, but, of course, in the 15 ft. furnaces with a large decrease of tonnage. With this to go on, it was decided to make the change. The space between the furnaces was bridged over, the jackets set up, and the closed-top and downtake added. This completed, the change to a larger furnace was made, taking down the end-jackets. In this way, with little interruption, a new furnace was designed, the 21 ft. intervening being thrown into one with the two original 15 ft. furnaces, making 51 ft. in all. A heavy blast-pressure, of about 40 oz. per sq. in., is used, and the new furnace has an output of 1,600 tons daily with a maximum, per furnace, of 1,850 tons. Besides the fact that it was possible to take down a jacket and to clean out a portion of the furnace while the rest was running, other advantages have shown themselves in operation.

With an increase of output equal to 3.8 times, the jacket-area in contact with the charge has increased but 2.4 times, so that, proportionally, less jacket-water is needed. Again, we may compare the large furnaces to those three small ones in which there have been omitted four out of the six end-walls of the latter. Now, since the end-walls are a fruitful cause of accretions, the improvement in this respect is evident. Furthermore, accretions are gotten rid of much more easily, either by barring off, or by smelting them on the long side-walls. The large furnace has retained the two fore-hearths or settlers belonging to the smaller two furnaces, and which are 16 ft. diam. by 5 ft. high. The increased flow through these settlers keeps them hot and in good condition, and has not interfered with a satisfactory separation of the matte from the slag. Were it desired to change the fore-hearth, this can be done by stopping the furnace tap-hole and compelling the mixed stream of matte-slag to flow through the other settler until the change can be effected. The mid-portion of the furnace, as already stated, has a bridge at the hearth-level, water-cooled to withstand the corrosive action of the slag. At this portion of the furnace, and to lessen such eating away, a more silicious slag may be used, while a slag of the ordinary composition can be taken for the ends. Also, if a crust at one end of the furnace needs the fusing effect of a basic slag, charges of that nature can be used. Practically the campaigns of these furnaces are of indefinite length, being only terminated by the lack of ore.

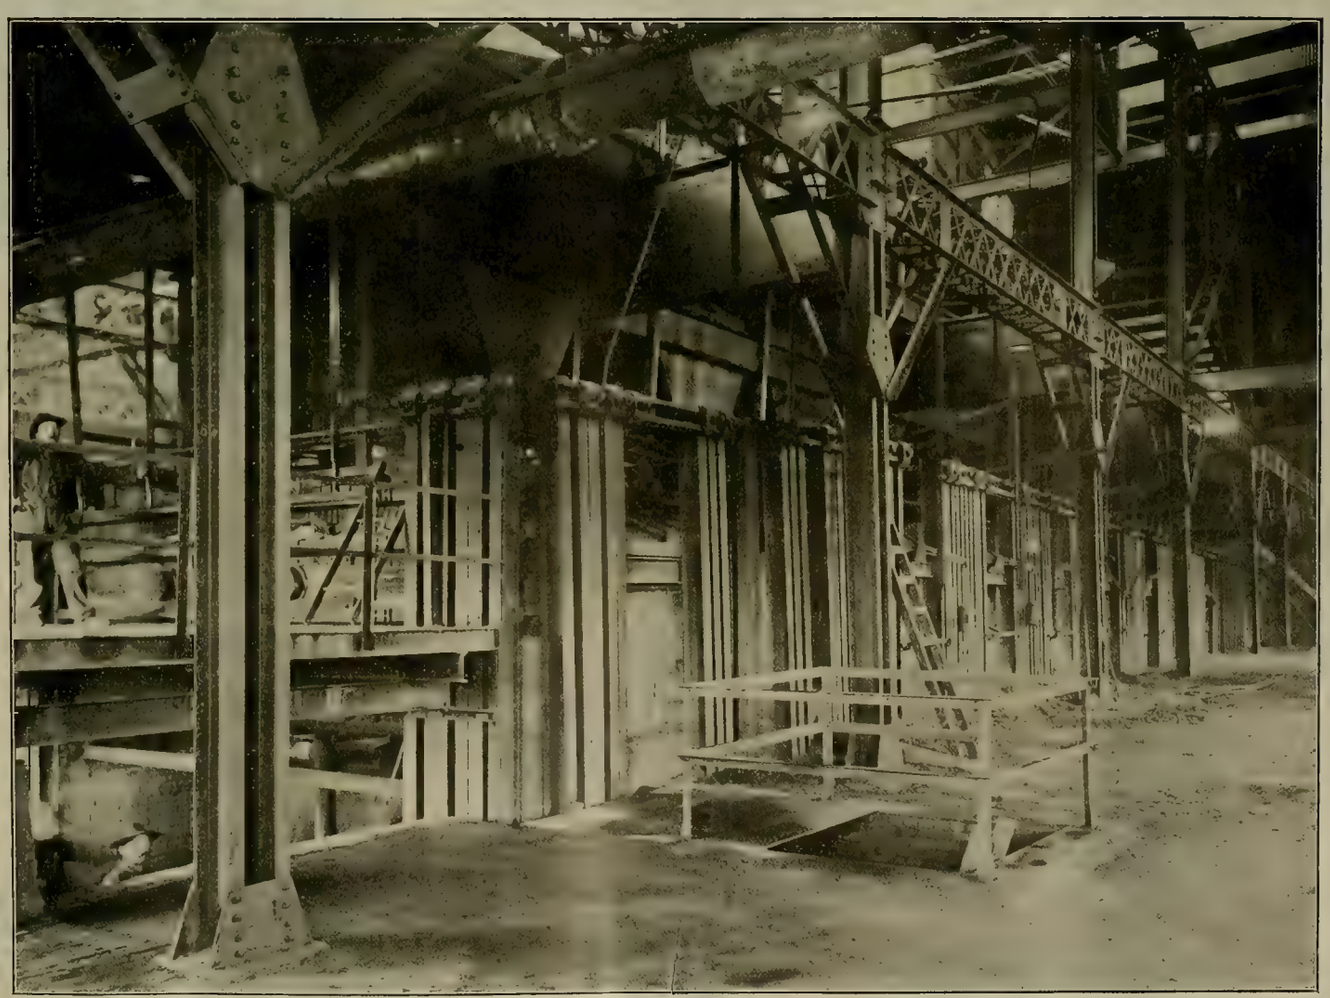
Blast Furnace, While Charging.

It is the custom of the Anaconda works to screen all their first-class ore through ⅜ in., the fine material being made into briquettes together with all the flue-dust of the plant and slimes from the settling-ponds, this last product assaying 2.5 to 5% copper. These products are made up into briquettes, being pugged and then put through an end-cut screw brick-machine at the rate of 840 tons daily. It is not attempted to dry these briquettes; they are charged to the furnace in a plastic condition. So well is the system arranged that there is no handling in the operation of briquetting. There is a string of 36 overhead hoppers each capable of holding 2,000 lb. of briquettes. Eighteen of these can be drawn off into a train of 18 charge-cars. These hoppers, or compartments, have hinged drop-bottom doors, all, or any, of which can be dropped by the movement of a lever. Thus, when the cars are set under them, they may be charged with a single movement. In the older practice of this particular plant a force of eight men was needed to prepare and dry 100 to 125 tons of briquettes. Now, with the same force, 840 tons can be turned out daily.

THE mining methods at present used in the Portland mine at Cripple Creek, Colorado, have been developed from years of experience with veins of the Cripple Creek class, and are considered as representing the best practice. The ore is first broken as coarse as possible, and the coarser waste sorted out and left in the stopes. As there is not enough of this waste to completely fill the stopes, it is necessary to use large quantities of timber to support the ground. In the past, such methods as sending all the rock from the stopes through the ore-houses, working the stopes without timber, etc., were tried and found to be more expensive than the methods at present used, and at the same time had a tendency to reduce the grade of the ore to a point lower than it would have been had proper care been used in eliminating the waste rock. The cause of this reduction in grade by allowing all the waste rock to go through with the ore is easily understood. As the rock passes from the stopes into tram-cars, into and out of skips, and at last into the ore-houses, more or less of the waste rock is broken into fines which it is impossible to eliminate. The caving system, as used in the soft iron mines, is entirely impractical because of the hardness of the rock, and the large amount of ore that is lost. The filling system, in which the broken ore is allowed to remain in the stopes until the level above is reached, and is then removed, is practical only where the veins are narrow.—From *Annual Report* of the Portland Gold Mining Company.



Blast Furnace, No. 5 and 6, with Settlers at Slag Floor, Washoe Smelter, Anaconda.



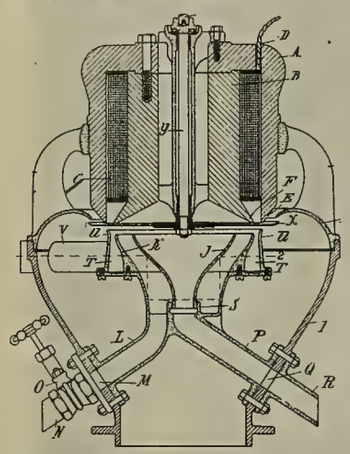
Reverberatory Furnace, Washoe Smelter, Anaconda, Montana.

Mining and Metallurgical Patents.

PATENTS ISSUED FEBRUARY 13, 1906.

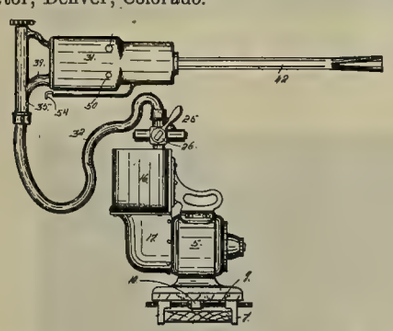
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

MAGNETIC ORE-SEPARATOR.—No. 812,173; G. Grondal, Djursholm, Sweden.



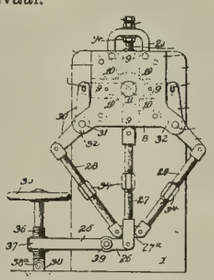
A magnetic separator for powdered ore suspended in water, comprising an upright cylindrical electromagnet having pole pieces directed downward in shape of concentric rings, beneath pole pieces a rapidly rotating disk mounted on a vertical shaft and beneath disk two annular vessels concentric to each other, inlet for fluid to outer vessel and adjustable discharge at bottom of inner vessel, space inside inner annular vessel being provided with outlet for fluid.

MEANS FOR OPERATING DRILLS.—No. 811,791; O. S. Proctor, Denver, Colorado.



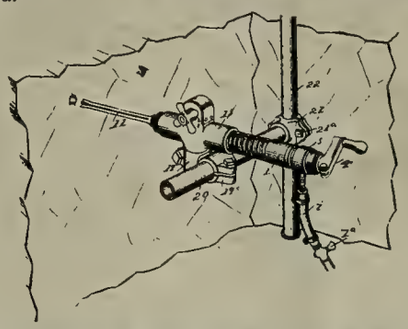
Combination of a motor-cylinder, piston therein, drill-cylinder piston constituting hammer, drilling-tool located forward of hammer and having longitudinal passage therethrough for delivering fluid to drill-hole, conduit between two cylinders, by-pass leading from drill-cylinder to point in front of drilling-tool, valve for controlling by-pass, valve mechanism for controlling passage of air between two cylinders, mechanism being constructed to allow air to pass freely from motor-cylinder to drill-cylinder during forward movement of motor-piston, while rarefaction of air in drill-cylinder is prevented during return movement of motor-piston, motor cylinder being supplied with air from atmosphere during reverse movement of its piston and adjustable means connected with drill-cylinder whereby air may be allowed to escape from conduit into atmosphere, or compelled to pass to drill-cylinder as desired.

APPARATUS FOR SHARPENING ROCK-DRILLING MACHINE BITS.—No. 812,570; J. A. G. Kirsten, Randfontein, Transvaal.



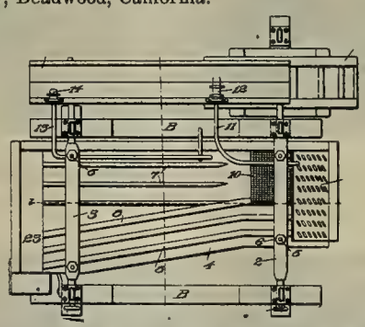
In apparatus for sharpening rock-drilling bits, main vertical plate, second vertical plate fixed thereto and having central aperture and vertical and horizontal guideways radiating from aperture, die-carriers in guideways, dies attached to carriers, a device for adjustably supporting top vertical die, levers pivoted to second plate and connected to horizontal die-carriers, lever pivoted to main plate and yieldingly connected with bottom vertical die-carrier and with levers operating horizontal die-carriers, and means for operating lever pivoted to main plate.

ROCK DRILL.—No. 812,375; C. J. Smith, Ottumwa, Iowa.



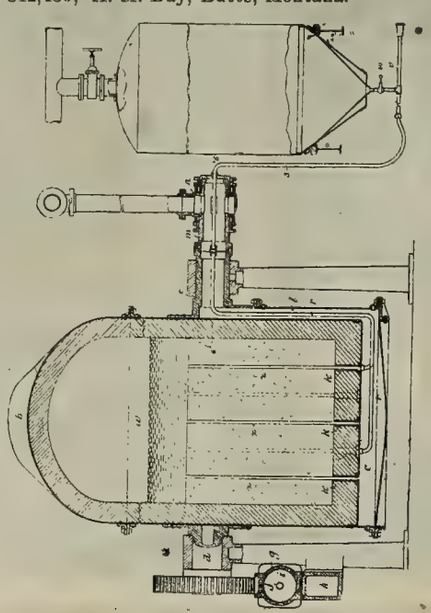
An apparatus of class described, comprising drill including casing and reciprocating hammer operable therein, drill casing having externally threaded portion, supporting casing having an internal bore for receiving drill casing, drill-casing-engaging member on supporting casing for engaging threaded portion of drill casing to lock same to supporting casing, means carried by drill casing whereby drill casing can be turned on longitudinal axis to feed same, drill casing and drill-casing-engaging member being so arranged as to permit drill to be automatically fed forward on its longitudinal axis at each forward impulse of the hammer.

GOLD-SAVING APPARATUS.—No. 812,474; O. H. Bagley, Deadwood, California.



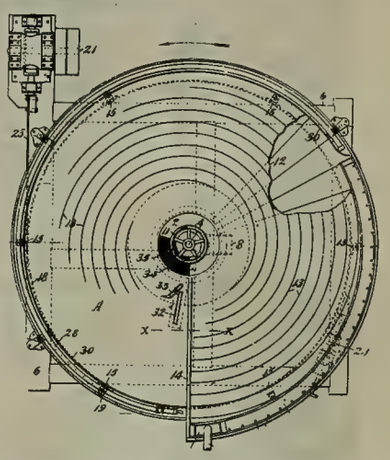
A gold-washer comprising table suitably mounted for reciprocatory movement, table having generally straight back portion with closed back and ends and opened at front, front edge of table made divergent toward rear of table, whereby latter has generally flared appearance from front to rear, series of riffles on surface of table extending approximately parallel with front divergent edge of table, means for delivering material onto head or narrower end of table, means for giving table longitudinal reciprocating movement, table having surface slightly higher at center than at either side, and means for adjusting transverse tilt of table.

APPARATUS FOR SMELTING AND CONVERTING ORES.—No. 812,186; A. M. Day, Butte, Montana.



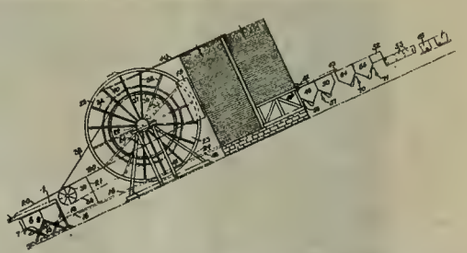
In apparatus for smelting and converting ores combination of smelting vessel provided with tuyeres and mounted on trunnions, one of which has a detachable extension forming therewith air supply connection to tuyeres, compressed-air-supply pipe provided with internally recessed sleeve in which trunnion extension is adapted to turn and through which it communicates with pipe, number of closed receptacles for holding fluent material connected at top with source of compressed air and having at bottom valve-controlled connections with auxiliary blast pipes which communicate with compressed-air supply and have flexible connections with trunnion extension, and pipes leading therefrom through associated trunnion to certain tuyeres and adapted to make tight joints with corresponding pipes in extension when it is attached to trunnion.

ORE CONCENTRATOR.—No. 812,520; J. W. Pinder, San Francisco, California.



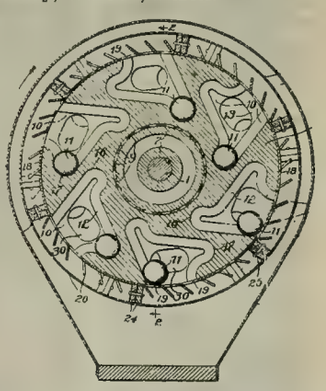
A concentrating-pan having concaved upper surface and mounted on central support, pan being essentially involute in outline, spiral riffles on pan and feed-box arranged around pan at the point farthest removed from central support, pan having separate discharges for values and worthless matter and means for giving pan an oscillatory movement.

APPARATUS FOR TREATING SLIMES, &C., FOR THE RECOVERY OF THE PRECIOUS METALS.—No. 812,418; C. Gluyas, Johannesburg, Transvaal.



In apparatus for treating metal-bearing material, elevating device comprising plurality of wheels, each provided with plurality of sets of elevating buckets, means for driving wheels, means for conveying material in succession to several sets of buckets, and aerating devices comprising superposed launders interposed in conveying means.

PULVERIZER.—No. 812,231; G. Raymond, Chicago, and J. H. Finlay, Warsaw, Illinois.



In pulverizing mill, combination with rotating drum, of pockets in drum, peripheral openings in pockets, tumbler balls confined within pockets, pockets being provided with inclines 15 and sockets 16, whereby balls are carried in pockets during upward part of their revolution and with raceways to guide motion of tumblers, cylindrical screen surrounding drum and rotating therewith, and scoops adapted to guide material to openings.

Stamp-Milling in Northern California.

Written for the MINING AND SCIENTIFIC PRESS by ALGERNON DEL MAR.

Those who have used triple or quadruple-discharge mortars have no doubt ascertained the fact that while a big tonnage is obtainable the extraction of the precious metals suffers in proportion. To obtain a high extraction and at the same time put through a maximum amount of ore is the object sought. Just where the line should be drawn will depend upon the treatment of tailing and the ore reserves of the mine.

The tests here recorded may be of use to those who have similar mills, a number of which have been discarded for five-stamp batteries, and with reason; but it may be possible that in some cases this substitution has been unnecessary and good results could have been obtained by regulating the conditions to suit a particular ore.

A close study of the physical and chemical nature of the ore may at once give hints for its proper treatment; in any event, the series of tests to be described ought to lead to a better understanding of what features to avoid and which to encourage in the process of reduction.

The ore in the Southern Cross mine of the Edel Mining Company in Butte county, California, is a pure quartz, very friable and easily slimed in a hand mortar. It contains about one per cent of sulphides, both iron and copper pyrite and galena, and on pulverizing the tendency is to make slime. These facts at once indicate the necessity for a coarse screen and medium discharge, or a fine screen with a low discharge, with a short drop in either case. The screen must be one that will not clog easily, allowing the crushed ore to escape without delay. In any case, for test-runs it is most important that the crushing be steady and the tailing of the fineness indicated by the screen, conditions which are unattainable if such an uncertain factor as clogging were introduced.

A moderate discharge is best with a coarse screen so that the heavy particles can be held back longer and the fine gold allowed an opportunity of amalgamating inside the mortar; while the low discharge and fine screen produce about the same percentage of tailing passing a given mesh, but tend to release the particles as soon as broken fine enough to go through the screen. Supposing the percentage of extraction to be the same in both cases, the choice would be with the one giving the greatest tonnage, this to be determined by experiment.

The Edel mill is composed of two batteries of two stamps each, in quadruple-discharge mortars. The stamps weigh about 950 lb. and drop 5½ in. 115 times per minute. Whenever the drop has increased (by the wear of the die) an inch, it is set back to 5½, thus permitting a variation of one inch. To make comparisons of tonnages, etc., as accurate as circumstances will allow, the speed was varied so as to produce the same energy at the beginning and end of tests. Only two factors, the drop and weight of stamp, could be taken into account, the former accurately, the latter approximately. As each individual machine is operated by its own water-motor, the speed of stamps was changed at will without interfering with the rock-breaker, electric-light generator or concentrators.

The battery plates are four feet wide and 19 ft. long, thus allowing 38 sq. ft. of amalgamating surface to each stamp and, with a duty of four tons per stamp, 9½ sq. ft. per ton per day, which is ample for all purposes. The pulp, after going through a mercury tap, discharges on Frue vanners, one for each battery.

It is possible with a battery of this type to obtain a duty of over six tons, but unless followed by a cyanide plant, the experiment is apt to be a financial failure, and, where it is not necessary to add the expense of cyanide treatment, there is no reason why such a big capacity should be sought. The ore is no sooner crushed to the mesh of screen than it is discharged on the plates; therefore, the amalgamating ability of a stamp battery—its only meritorious feature—is nullified or ignored. As far as crushing to a desired mesh is concerned, the stamp-mill is not an economical machine, but its usefulness as an amalgamator cannot be surpassed. Aside from the influences of inside plates — and consequent inside amalgamation—including the factors of discharge, height, drop, weight and speed, this high tonnage swamps the plates and delivers to the vanners more material than they can concentrate effectively.

To start with, three sides of the mortars were closed, leaving only the front screens to do duty. The screen-frame opening being only 19 in. long horizontally, it compares favorably with a standard five-stamp battery. Copper plates were attached to the three closed sides, but they scoured so that a protecting screen was needed. For this purpose, a half-inch mesh steel-wire screen was used, and it served the purpose very well. The object of inside plates was to endeavor to catch the fine gold before it could leave the influences of finely divided quicksilver and the successive splashes of the pulp inside the mortar. Two-splash plates and a lip-plate completed the amalgamating devices.

After starting a new run the inside and splash plates were kept stiff for a couple of days and then allowed to harden, the splash-plates being brushed only when stained or not completely amalgamated all over. The battery plates were kept fairly stiff, but always soft enough to brush up and rubber off the amalgam; but were never soft enough to run. No scraping tools should ever be permitted on silvered plates nor should they be scratched in any way by walking over them or throwing screens or other articles upon them. No chemicals of any sort were used, not even a harmless wash of soap and water. Proper rubbing at the right time and the right amount will keep most plates in good condition, but rubbing without any specific purpose will do more harm than good.

The battery plates were brushed twice a day; at midnight, when the plates were simply cleaned and any loose amalgam taken off, and at midday, when the accumulated amalgam was rubbed up and taken care of. The noon clean-up occupied about 20 minutes per battery, while the midnight one took about half that time, thus losing half an hour per day on each battery.

After his noon dinner, the amalgamator hung up a battery, turned off the water, hosed the plates and sprinkled mercury according to the state of the amalgam. This was well rubbed in with a whisk broom, softening the amalgam so that it could be easily moved; it was then collected at the center of the plates by using the rubber. This was done lightly so as not to rob the plates completely, but leaving sufficient amalgam as a groundwork, for not only has gold a greater affinity for amalgam than mercury alone, but plates left without protection are apt to become hard and spotty. This amalgam being taken up in the scoop, the plates were brushed up toward the head with a whisk broom held with the straw ends away from the operator. Then the plates were brushed lightly horizontally so as to present an even, fine grain, with no lumps. The hose was now turned on and any loose amalgam escaping was washed into a tray previously inserted in the box at the bottom of the tables. I have known where this expedient saved half an ounce or more per day, but the mill was running on $40 ore and the plates had to be brushed every four hours.

The 19 ft. of plates before-mentioned are made up of five plates four feet each, one foot being taken up for overlap. There are no screws used in the plates at all, each plate overlaps the next below and is held down solely by side strips which are gained to fit the plates accurately, therefore preventing any plate from slipping. Every millman will appreciate the absence of screws when cleaning up. I believe the idea is due to Mr. Emile R Abadie, formerly superintendent of the North Star mines, at Grass Valley.

Samples were taken every hour from the feeders and tailing coming from concentrator, quicksilver being fed at the same time. Determinations of fineness of crushing were made on samples from the accumulated tailing, for the tailing running to waste varied so much that unless taken over an extended period the samples were useless. The amount crushed per stamp per hour was determined twice daily by noting the time required to fill a 20-gal. tub, allowing to settle, decanting the clear water, drying and weighing. Only two sizes of screens were used, for while sizing to many meshes may be of technical interest to a few academically inclined, it is of little practical use.

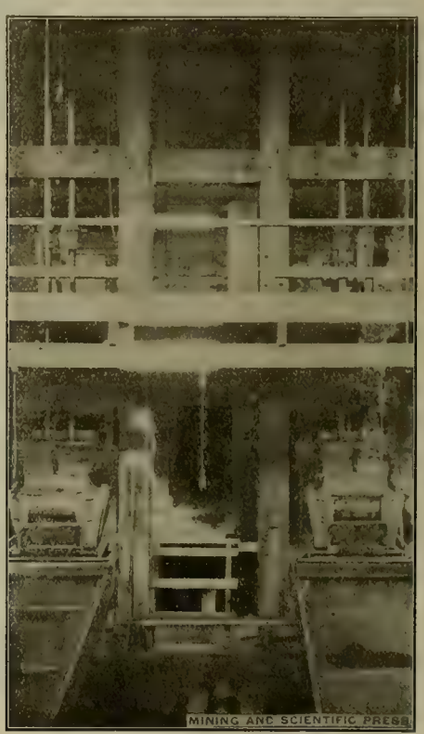
All abnormal determinations were thrown out. On the whole, the results, for a given discharge and drop, were consistent. With the needle-punched Russia-iron screens the results varied as much as 50%, while with the wire they often agreed within half of one per cent.

On account of the excessive clogging, and consequent variation in results, the needle-punched screens of thick iron were discarded and the choice then lay between a wire screen or a needle-punched tin screen or, what amounts to the same as the latter, a blued steel screen, both being of thin iron or steel. These are the only freely discharging screens known to me, except for coarse meshes, when a slotted screen does good work. The wire screen selected was a double-crimped No. 6 mesh steel wire, which seldom clogged while the tin screens often did, especially the finer meshes. The ratio of the times necessary to scrape the wire as compared with the tin screens (blued steel included) of the same mesh would be about one to five, so that, on the whole, the wire screens are better for testing purposes, where uniform conditions must be maintained.

If it is desired to maintain a certain discharge,

Quadruple Discharge Mortar.

Edel Mill.



Interior View of Mill.

there is no reason why a screen should be used that will change that discharge an inch or so by its clogging; and as the discharge is the most important factor of all, the moral is to find out by experiment the best screen (not necessarily the cheapest) and the best discharge, and stick to them as long as that particular ore remains the same physically and chemically. The following tests extended over a period of about six days each:

TESTS.

No.	Screen.	Size of openings—inch	Discharge—inches	Per cent through 60-mesh brass wire	Per cent through 40-mesh brass wire	Assay of tailing	Tonnage per stamp per 1b.—hour
1	No. 6 wire	0.027	6	64	88	0.90	300
2	No. 4 blued steel	0.035	6	70	88	1.20	270
3	No. 6 wire	0.027	5¼	58	81	trace	320
4	No. 0 tin	0.024	5½	91	94	0 90	131
5	No. 4 blued steel	0.035	5¼	64	88	trace	280
6	No. 6 wire	0.027	4½	45	86	1.45	340
7	No. 0 tin	0.024	4¼	70	85	1 85	146
8	No. 6 wire	0.027	3½	33	79	1.45	420
9	No. 0 tin	0.024	3½	50	80	0.94	360

The results show that not only does the wire screen give the highest tonnage, but also a better extraction, except in the case of a 3½-in. discharge where the tin screen of fine mesh gives a better result than the wire screen of coarse mesh, but not as against the wire screen with a higher discharge (Test No. 3), where the tonnage is higher and extraction better. The ore averaged about the same for the nine tests, except in the case of No. 5, which was of much lower grade; but even in this case, the tonnage being less than No. 3, the result would be discarded.

To ascertain where the gold escaped, in some of the runs the tailing was separated into fine and coarse, with the following results:

First test tailing assayed	$1.24
Passing 60-mesh	1.24
Not passing 60-mesh	Trace

To make sure of this point, another series was run as follows:

Passing 60-mesh	$4.36
Passing 60-mesh after washing off slime and heavy particles	0.30
Slime washed off	6.18
Coarse material	Trace

This proves the point conclusively that the values were being carried off in the fine material, therefore a screen must be used that will discharge freely and the discharge kept at such a height that the gold will have time to amalgamate, without sliming either the gold or the sulphides.

This also answers the query of one of your correspondents in respect to sliming ore as carried out in Western Australia. The answer is that each particular ore requires a particular treatment. In this case, what would be the use of sliming that portion of the ore that contains only a trace? The object in this case is to prevent sliming; for the more the slime, the more gold escapes in the tailing. It is surely more economical in this case to crush to 0.027 in., say 25-mesh, and concentrate, than to slime the whole material and cyanide afterward.

By plotting the results in terms of tonnage and screening, two curious facts are observed: first, that while the fineness of crushing varies directly as the discharge, the tonnage takes an abnormal jump between 4½ and 3½ in. This is, no doubt, due to two factors, the specific gravity of the ore and the shape and size of the mortar at the screen-opening. The conclusion is that on some ores at least a quadruple-discharge battery can be arranged to do good work, both as to extraction and tonnage. The most important factors to be considered and determined by experiment are the height of discharge and the size and character of screen.

SURFACE AREA OF SCREENS.—In view of the fact that the efficiency of the subsequent metallurgical processes depends largely upon the surface areas of material exposed by crushing, it may be noted that, given equal weights of similarly shaped particles, the relative total surface areas are inversely proportional to the average diameters of the particles in each case. For instance, sixty-four 1-in. cubes expose four times the surface area of one 4-in. cube. Hence, simple ratios between relative screening apertures facilitate comparisons of surface areas. According to Rittinger, the work done in crushing is proportional to the reduction in diameter or the increase in surface exposed.—W. A. Caldecott.

THE Mexican International Railroad has handed over to the Mexican Coal & Coke Co. its coal mines at Sabinas, receiving in return the railroad which the coal company has been operating from Baroteran, on the main line of the International, to Muzquiz, where the coal company has mines. The coal company's railroad is said to have been valued at $400,000 gold. With the exchange there is understood to be a stipulation that the coal company will furnish coal to all the divisions of the national lines of Mexico at a fair price. The coal output is expected to increase under the new management. Meanwhile some of the Mexican railroad divisions are making experiments with crude oil in their engines.

Handling Men Underground.

Written for the MINING AND SCIENTIFIC PRESS by R. B. NICKERSON.

The man most closely identified with the handling of large crews of men underground is the mine foreman. He must, necessarily, be a master in the art of mining and a man of strong and vigorous constitution, to stand the heavy mental and physical strain, for upon his shoulders rests, primarily, the responsibility of the safety of the crew and the profitable extraction of the immense daily tonnage of ore required by a modern crushing plant. Of these mine foremen, those who have made the greatest success are of two distinct types, and their methods of handling crews are radically different and distinctive. The first, we will say, is of the aggressive, self-assertive, dominant type. He rules his men with an iron hand. He is very hard to please and is seldom satisfied with the work done, and the slightest infraction of his strict rules calls for instant dismissal. He is close-mouthed and secretive; forms no friendships, trusts no one. He sees to it, personally, that every man under his charge is working hard; he judges a man not by what he accomplishes, but by what he sees him do. He favors the practice of 'rushing,' that is, putting a Cornish crew against an Irish crew, or an American gang against an Italian, in the same stopes, but in opposition shifts, and then counting the cars on them. He has no regular time for making his trips through the mine. He may appear in any part of the workings at any moment, and he expects to find everyone hard at work. He makes 'sneaks' on the men and watches them when they least suspect it. He is a man of few words and quick decision. It is either yes or no with him. He neither asks nor expects an opinion regarding any of the work. It must all be done his way. Even his shift-bosses have but very little license. If it were possible, he would direct the pitching of every hole and the driving of every wedge. He makes his mind up himself how any piece of work should be done, and gives his orders accordingly. "If you're a boss, be a boss," is his motto. In a word, he dominates the mine with his own personality. Full of nervous, tireless energy, he works his crew to the breaking strain all the time. He has no preference for married men; he thinks, and says, that if a man works six months in a mine it is long enough. Frequently he changes men who are partners and getting along well together; also he changes parts of shifts who are working in some particular stope to another stope, and for no apparent reason. In fact, he adopts a policy of constantly harassing and surprising his crew. They never know what is coming next. Mines handled in this way are the ones where men are constantly coming and going, and where the monthly payroll has frequently more than twice the number of names than are actually at work in the mine.

The other type of mine foreman is in all ways radically different from the type just described. Of course, they both take their general orders from the superintendent, but he seldom interferes with the detail work. The superintendent, of course, is the 'main push' when it comes to any show-down regarding any part of the mine or work, but he seldom interferes with his foreman, after once giving him his general orders. This second type, so to speak, of mine foreman is quiet, genial, courteous and pleasant in all his dealings with his men. There is nothing bombastic about him. If he thinks a man is trying to do his task, he makes allowances for him and overlooks a good deal, and tries to make a good workman out of inferior material. He seldom 'fires' a man, but is very careful whom he puts on, sizing up an applicant from every point of view, as to his ability, experience, character, etc. He trusts his men and makes friendships that last a life-time. He judges a man's work not by what he sees him do, but by what he accomplishes, and the showing he makes. He is strictly opposed to the practice of 'rushing' and tries to encourage friendly feeling among his crew. He has his regular hours for making his trips through the mine and his men always know when to expect him. He never makes 'sneaks' or covertly watches them; he seldom starts an important piece of work without first calling a consultation of the shift-boss, timberman and some of the first-hand men who are to work there. The matter is fully discussed, in all its details, and a plan formed and agreed upon, in which all express their views. This man thinks "two heads are better than one, even if they are both mutton-heads." He has a decided preference for married men. He seldom changes men who are working partners, or changes parts of a shift from one stope to another. He likes steady men and it hurts him when a good man quits. Mines handled in this way are the ones whose men work till they are old and gray, raise families around, and the sons follow in the footsteps of their fathers.

Those are the two general types of mine foremen, handling the men who are taking out, mostly from immense depths, the great bulk of the world's supply of gold. Both are sincere and earnest. Both are successful and each is straining every nerve and fiber in him to take out the ore in the best and cheapest way possible consistent with good mining. Their ways are radically different, but they are both faithfully striving to accomplish the same end.

To Those That Use Powder.

The following cautions to miners appear in the last Annual Report of the Inspector of Mines, Idaho:

Don't start to drill in a new face until you have thoroughly satisfied yourself that there are no missed holes or unexploded pieces of powder left in the old butts or cut-off holes. If such are found, re-prime and shoot them before starting in to drill, as a slip may connect with the charge that will transmit a sympathetic concussion from the drill, especially if a machine is being employed that may explode a charge while drilling.

Don't depend entirely on reports. It often happens that the upper part of a charge will explode and the lower part remain alive and unexploded without going off.

Don't be in too big a hurry to go back to a burnt hole or 'stinker,' or to re-prime a missed hole, for it is safer to re-prime within an hour, say, than to work over a hole that has missed fire for a half shift, as missed holes will remain apparently dead for several hours without any sign of life, and then, unexpectedly go off. Several cases of this kind have occurred in the State recently with disastrous results.

Don't use any kind of metal tamping bar or tap a wooden one with a hammer when loading.

Don't carry a lighted candle together with powder or a capped fuse in the same hand.

Don't keep caps and fuse in the same place with powder.

Don't store powder in the same room with oils or other inflammable materials.

Don't thaw or keep powder in a blacksmith shop or a dwelling.

Don't jab too hard with a wooden tamping bar, in case a piece of powder fitchers or sticks half way in a hole, when loading, and you can not push it home gently. Never mind your reputation as a loader. Let the hole spoil. If it should result in your losing your job you will have yourself left, anyway.

Don't carry powder about your person to soften it, or attempt to thaw it in the flame of a candle, or crimp a cap with your teeth, or 'break' a stick in two. Cut it, no matter how dull your knife is, and if you haven't a knife, go and get one.

Don't jab a pick into a muck pile in the manner of striking a drill with a double hand hammer. You are likely to hit a stray piece of powder that will explode and blow your eyes out. Three such accidents have happened in Idaho during 1905. Use your pick to work the stuff down with more of a raking motion. It is safer, and just as effective.

Don't take a naked light into any warm storage place for powder or sub-magazine, or hang a candle over an open box of powder or scatter particles of powder in making a hole for a primer where they are likely to strike a candle flame.

Don't carry loose powder in your arm. Use a small canvas sack which you can swing over your shoulder with a rope loop.

Old powder is dangerous to handle in many ways and hard to explode. Demand fresh powder and strong caps. By practicing the above rules and using ordinary care, you will experience little trouble in handling powder.

HUNTINGTON-HEBERLEIN PROCESS.—An important improvement in the metallurgy of lead has been effected by the introduction of this which consists in heating a mixture of galena and lime at 700°C., then cooling to about 500°C. and passing a current of air through the mass, when sulphur dioxide is evolved. The process is continuous, the atmospheric oxygen interacting with the ore so long as any sulphur is present. In the Bradford-Carmichael process gypsum or anhydrite takes the place of lime, either of these minerals in the form of a sludge being intimately mixed with the lead ores and the dried mixture being subsequently heated in a stream of air. The issuing gases, which contain about 10% sulphur dioxide, may be utilized in the production of sulphuric acid. Two alternative explanations are given of the former of these processes, the first being that the lime becomes oxidized to calcium peroxide at 700°C. and that this compound is decomposed at 500°, the oxygen set free oxidizing the lead sulphide to lead sulphate. This sulphate then reacts with more sulphide yielding lead oxide and sulphur dioxide. The second hypothesis is that the lime and galena interact to form lead oxide and calcium sulphite, the latter compound then becoming oxidized to calcium sulphite or sulphate which partly becomes converted into calcium plumbite or plumbate while the remainder reacts with galena forming calcium sulphide and lead sulphate.—*Chemisches Central-Blatt.*

THERE are few if any countries in Europe that surpass Austria-Hungary in mineral wealth. Mining has been a favorite pursuit for centuries. Coal leads in production and value. There are more than 225,000 persons employed in mines. The annual output of rock salt is large, there being no less than 10,000 persons engaged in this industry. Of the other minerals, gold, silver and iron are produced in large quantities, the exports running into millions of dollars annually. Mineral springs are in abundance, the waters from which are sold in nearly every country in the world.

The Possibilities of the Tundra.

By Otto Halla.

Ever since the strike made by J. O. Brown on Little creek, the tundra at Nome has commanded attention as a possible big producer of gold; since then the fabulous find made on the Portland Bench has convinced the most pessimistic prospectors and miners that the tundra offers better prospects than any creek or hillside in the Nome district.

Sixteen men were working on the Portland Bench for 60 days and they have made a clean-up of $720,000. It cost them about 2% of this yield to work the ground. During the summer months of 1905, seven miles southwest from the Portland Bench a new strike was made on Jess creek, the claim finally being bought by Lane & French for $125,000, who expect to take out of it this coming winter about $500,000. These strikes are facts which cannot be disputed; the question is now: What likelihood is there of finding more ground like it, and what caused deposits of gold of such richness to be accumulated in these spots?

There is, in the immediate vicinity of Nome, an area of about 100 square miles of tundra ground (between Cape Nome and Cape Rodney) which is equally well situated and which is liable to have gold gravel in paying quantity or accumulated spots of a richness equal to that of the Portland Bench. The tundra is composed of strata of blue clay, interlined with layers of gold-bearing gravel, and all containing more or less gold; in some instances the gravel containing gold has a thickness of 20 ft. and more.

J. C. Brown's Claim, Little Creek, Nome.

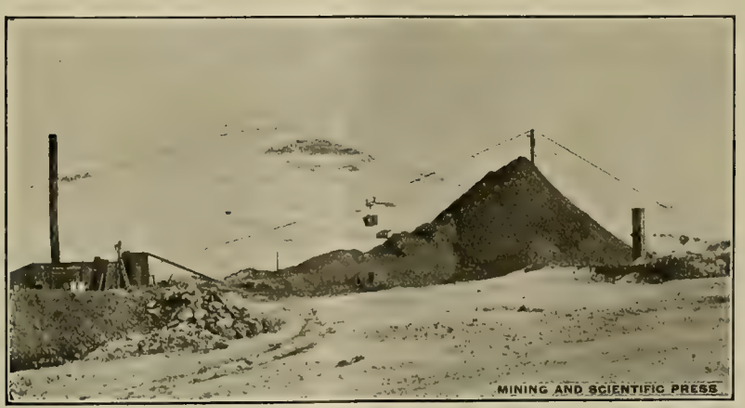
The sea undoubtedly has played an important part in the accumulation of the rich spots, as was demonstrated in the case of the beach deposits, which caused the big stampede to Nome in 1899. It is also certain that the Bering sea is receding every year, or else the mainland is rising. The debris washed down from the hills has a tendency to fill up the shallow water contiguous to the mainland. The sea, therefore, must have been at one time very close to the foothills, gradually receding until it reached the present level. The same agencies that have deposited gold on the present beach must have deposited gold on the ancient shore. It is claimed now that in the Portland Bench the gravels are beach pebbles; if this be so, the evidence is conclusive that the action of the sea has accumulated the gold deposits found at that particular locality.

Old and New Method of Mining.

Wherever a gold-bearing creek emptied into the sea, there at that particular spot is the place for a rich deposit, the sea constantly washing the gold and separating it from the debris. It is now conceded that there are several ancient beach streaks in the tundra of Nome; but on account of the foothills and the difference in the elevation of the bedrock, the regular channel has not yet been found or followed; but, undoubtedly, in the very near future the paystreaks in the tundra will be better understood, as a good deal of prospecting is being done at present and new finds are made constantly.

However, on account of the vast territory to be prospected, not much can be done in one or two years, for the present method, that of a steam-boiler and hand-windlass, is a very slow process. When drilling becomes the fashion, a greater territory can be tested in a short time; but this requires the investment of so much more capital, which has not come to the help of the Nome tundra prospector as yet.

The Snake River basin is especially favorably situated and is likely to have several gold-bearing beach-streaks, as the watershed of all the best gold producing creeks slopes toward it; but the area is so vast, that it will require a good deal of money to institute a systematic search.



Little Creek, Nome, Alaska, in the Winter of 1905.

According to L. Vogelstein & Co., of New York, the German consumption of foreign copper for the months of January to December, 1905, as compared with the same period of time for 1904 and 1903, was:

	1905. Tons.	1904. Tons.	1903. Tons.
Imports	109,159	116,670	88,792
Exports	12 351	9 341	9,999
Consumption	96,808	107,329	78,793

Thorium.

From its discovery in 1828 until quite recently, thorium belonged to that class of the rare metals whose occurrence is of greater importance to chemical speculation than to industry; but the invention of the gas-burner mantel and the experimental determination of the illuminative quality of its oxide removed it at once from this class into that of products that are indispensable. It has been admitted that the salvation of gas as an illuminant in competition with other lighting methods lay in the invention of the gas mantel, which is made by saturating a network of cotton with a solution of the combined nitrates, oxides, or bromides of thorium and other metals of the same serial group. Incineration converts the metal into its oxide, and under these conditions thorium has established its superiority over related elements, not only in virtue of higher illuminating power—increased by the addition of small amounts of uranium and cerium oxide—but also by the preservation of a serviceable minimum of stability after ignition. The metal is of fairly wide range; in thorite and orangite it occurs in Norway—the land of its original discovery—and in the Champlain iron region of northern New York as urano-thorite. The singularly delicate and prolonged manipulation necessary to the exact determination of the metal, and even in cases to its recognition, is a stumbling block in the way of the prospector, and not infrequently leads to confusion, as recently in Ceylon, where a supposed deposit of pitch-blende turned out on analysis to be a new mineral containing 76.32% of thorium oxide. The best known, and commercially the most important, occurrence is the monazite which is abundantly distributed as a minor constituent of the gneissoid rocks of Brazil and North Carolina. The high specific gravity of the cerium group of metals renders them peculiarly susceptible to mechanical concentration after the disintegration of the containing mineral and monazite sands, which are due to selective marine action, and cover large tracts in Brazil, have hitherto constituted the chief source of supply. Monazite, which in its essential character is an anhydrous phosphate of the rare earths of the cerium group, contains varying quantities of thorium, and it is to this that its commercial value is referable. The Brazilian production, in correspondence with the demand, has shown remarkable expansion during the past four years, the figures being as follows: In 1902, 811 metric tons of the value of $81,115; 1903, 3,299 tons valued at $355,876; and 1904, 4,860 metric tons valued at $522,360. Its export to Europe, where the control of the market has lately been in the hands of a German syndicate, was originally, it is believed, in the form of ballast, but the recognition of its value was not long delayed, and prospecting has enlarged the bounds of its known occurrence. To the opening up of these further deposits, and to those in the northern half of the American continent, the consumer is at present looking for relief from the artificial conditions which at present exist in connection with the commercial control of the metal. During the last four years prices have been gradually raised in accordance with the growing demand, until quite recently they stood at London as high as 53s. per km. less 7% and other small rebates. Suddenly the price has dropped to 27s., and it is considered that competition is in course of maturing on a scale which makes the syndicate's control seriously concerned as to its present condition, and desirous, if possible, of forestalling it. Both in Brazil itself and the Carolinas arrangements are in progress which are expected to give a substantial stimulus to the production of the metal, while the high range of prices has naturally imparted a considerable impetus to prospecting both in Australia and Ceylon.

Operation of Rock-Drills.—I believe in a man working his machines as near together as possible, preferably on adjoining benches, if the ground admits, whether he is bringing the benches down or working back from the stope bottom. The latter system is, of course, inapplicable in steep stopes. In such safety requires that the benches be followed down, but in a stope of 35° dip or less my preference is to open out the bottom from the winze, undercutting as far as the first box hole on each side, and gradually forming the whole of each face into benches, extending from winze to box hole; then starting at the bottom to work back to the last bench, return to the bottom, break out the dead end and work, re-treating again, and so on. It is evident that drills should be kept on adjoining benches to maintain the sequence; no man should blast his own front and back holes bored on the same shift, and where a bench does not break properly, it must be put in shape before the work proceeds. With this system the ground always breaks away from the machine and toward the stope boxes, thus materially aiding in shovelling; the benches are never so buried with broken rock as when they are carried down and the leader is thus more easily followed; there is less tendency to bore holes into the hanging wall, with the consequent increase in waste, and the machines lifted from the bench they have drilled today are safe on the one they must drill on tomorrow, and, if time admits, may be rigged up and left standing for the next shift, thus saving time. The system lends itself to the shaping of pillars on the lower side, and by starting at the right distance above the pillar and benching down to it, the face of the stope, when the pillar is holed, is in such shape that the benches above and below readily merge into each other. Finally, the system requires less room. You may work four machines to the best advantage on a 100 ft. face if they break ground properly.—Wager Bradford in *Jour. Chem., Met. & Min. Soc. of S. A.*

Building a Concrete Tank.

About a mine or mill it is often desirable to build a water tank. Ordinarily they are made of lumber, and, although answering the purpose for which they were constructed, often leak and are otherwise unsatisfactory despite the pains taken in their making. The following suggestions have been made by John W. Ferris, of San Francisco, on the construction of a concrete tank, which may be of use to those contemplating the building of a small tank for permanent use. The accompanying sketches will aid in an understanding of the description:

Level down the ground where the tank is to stand, and if it is not firm ram it thoroughly. Drive a short stake as a center stake. Take a piece of batten 6 ft. 6 in. long, and 3 in. from each end enter a spike; drive one of these into the stake that was driven into the ground and let the other project an inch or so; then with a spike that is driven into the stake as a center, mark out a circle which will be 12 ft. in diameter. Take 18 stakes of 2 by 4-in. pine, 4 ft. long, pointed at one end; drive these about 2 ft. apart with one of their 2-in. faces to the circle marked on the ground, taking care to have them all plumb. Round the bottom and outside of this circle of stakes nail a strip of board ½ in. by 6 in.; this circular enclosure, 12 ft. 8 in. in diameter, is to be filled with concrete thoroughly tamped, for the bottom of the trough.

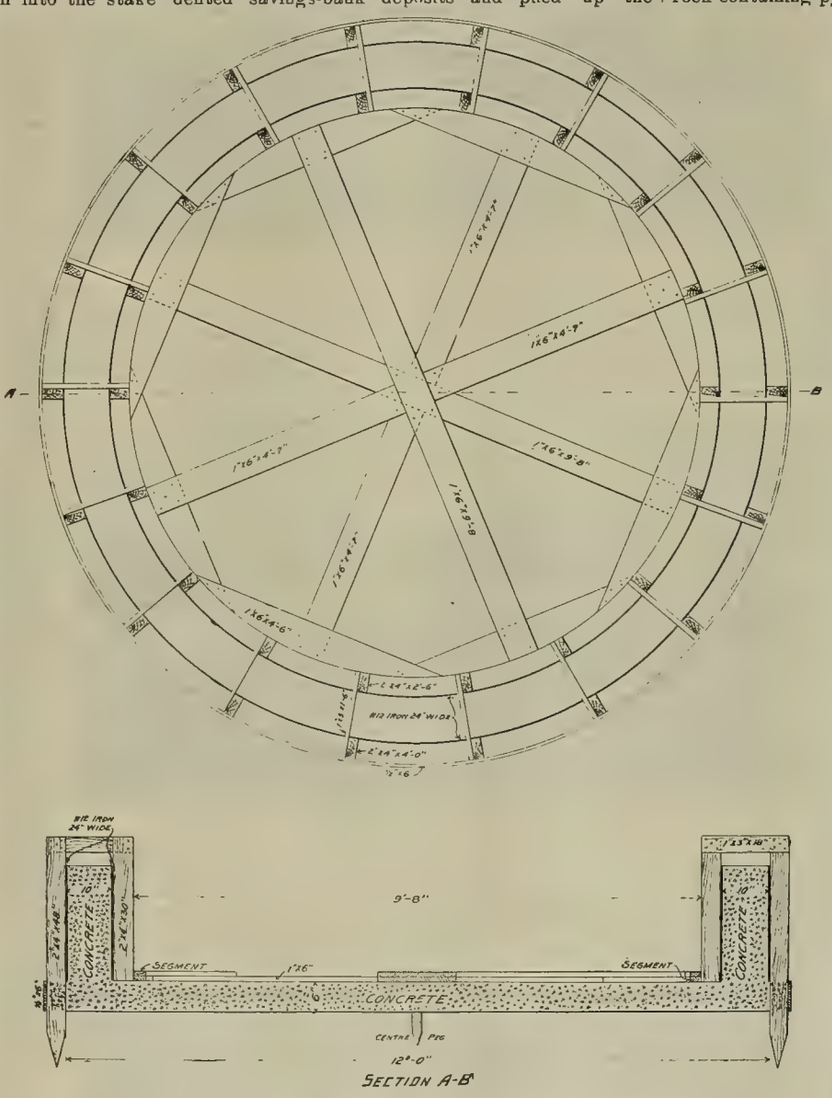
Take eight lengths of 1 by 6-in. fence board, 4 ft. 6 in. long, and the batten that was used to strike the 12-ft. circle, set the spikes 4 ft. 10 in. apart, and mark off the lengths of fence board into segments of circles.

Lay these segments down in a circle 14 in. inside the inner edge of the stakes that were set in the ground; let the segments overlay their ends 6 or 8 in. and nail them together, then take lengths of fence board and set across the circle, nailing their ends at the middle of the segments, to hold them securely in place.

Take 18 pieces of 2 by 4-in. pine, 2 ft. 6 in. long, and 18 pieces of 1 by 3-in. batten, 18 in. long; set up one of the pieces of 2 by 4 opposite each 2 by 4 stake, and nail the batten across at top to hold the 2 by 4s 10 in. apart; the segments serve to hold the upright at the bottom.

Take half-inch boards and tack to the 2 by 4s to make the forms for the wall of the tank. A much better looking job can be made by using sheet-iron instead of the boards one length, 2 ft. wide and 36 ft. long for the inside and 2 ft. wide and 38 ft. long for the outside.

Nail some boards together to make a box without any bottom, measuring (inside) 3 ft. square and 18 in. deep; this will hold half a cubic yard. Fill this with gravel; lift off the box and spread the gravel out in a layer 6 in. thick; over it spread three-quarters of a barrel or three sacks of portland cement. Turn this not less than twice before adding any water. Sprinkle over it 15 gal. of water and turn twice more. Then between the sheet-irons fill in the concrete in 6-in. layers, tamping each layer thoroughly, till water shows on top of the concrete.



Construction of a Concrete Water Tank.

There will be needed altogether 5 cu. yd. of concrete; for this any clean creek gravel will serve, at the rate of 1 cu. yd. of gravel to each barrel and a half of cement, or if the cement is in sacks 1 cu. yd. of gravel to six sacks of cement.

The tank will hold level full a liberal 1,200 gal. I have tanks made this way that are five or six years old and have never leaked. The round tank is better looking than a square one, and is not so likely to be broken. The cost of material will be:

For hauling gravel, say	$ 5
For 7½ bbl. cement	15
For lumber for forms	5
Total	$25

Or if the sheet-iron lining for forms be used add $20 extra.

STEEL CONSTRUCTION.—The recent computation showing that 200,000 tons of structural steel will be required for buildings to be erected in New York the coming season, and for which detail plans have already been made, indicates how large a factor such operations are in the present prosperity of the iron trade. This tonnage represents projects on which contractors' bids have been asked, and that are expected to be carried out unless interrupted by financial or industrial developments calculated to check all business. It is entirely reasonable, in view of these figures, to look for the placing of 300,000 tons of structural steel for work in New York alone before the end of the year. The total placed in the year 1905 for use in New York City has been closely calculated, and is found to be somewhat above 200,000 tons. Structural steel sells at nearly twice the extreme low price touched in the nineties, and yet in comparison with many products now and with its own high records of boom times it is at a moderate level. Real estate is high, and securities, while high priced, are still attractive as compared with the returns of city buildings, based on present costs of labor, ground and materials. Instead of being a badge of industrial distress, as it was ten years ago, the present building movement results from an overflowing prosperity that has accumulated unprecedented savings-bank deposits and piled up the surplus of the wealthy beyond any dream of a decade ago. The new buildings of today are going up because the growth of the great cities of the country requires the tearing down of the old, to be re-placed by what is better and larger.—*Iron Age.*

VANADIUM.—This rare metal has come into prominence within the last four or five years, on account of the great increase in tensile strength, elasticity, and ductility it imparts to steel when added only to the extent of about 0 2 to 0 5%. Its most important ore is vanadinite or chlora-vanadate of lead. In the pure state it should contain 19 35% V_2O_5, but the ores actually used for the manufacture of ferro-vanadium generally only contain in the neighborhood of 10% V_2O_5. Such an ore is worth in London about 4s. to 5s. per kg. of V_2O_5 contents, assuming that it tests over 10%. The metal is found in quite a number of rare minerals, such as dechenite, vanadite, carnotite. etc. The ash obtained from anthracite, found at Yauli, in Peru, is said to contain as much as 25% of V_2O_5. A French company was to be started to exploit these deposits, but so far nothing has come of it. Vanadium ores are found in limited quantities in Spain, the Argentine Republic, Mexico, Sweden and the United States.—O. J. Steinhart, *Trans. Inst. M. & M.*

The Prospector.

Enquiries sent to this department are answered free of charge. If submitted by subscribers who are not in arrears The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question No assays are made.

The ore from Inyo county, California, marked T. W. P., is quartz with molybdenite. The yellow mineral is molybdite, the tri-oxide of molybdenum.

The ore from Oasis, Esmeralda county, Nevada, is mostly quartz, with clay and ferric iron. A few small crystals of wulfenite (lead molybdate) are also present. The accompanying rock, marked No. 2, is granite.

The rocks from Waldo, Or., marked 'C. S. B.' are: No. 1, serpentine; No. 2, granular quartz; No. 3, syenite; No. 4, syenite; No. 5, a syenitic or granitic rock containing pyrite and chalcopyrite (copper sulphide), and also principally pyrrhotite. No. 6 is calcium carbonate; No. 7, syenite; No. 8, norite.

The rock specimens from Yerington, Nev., are classified as follows: No. 1, quartz-porphyry. It often occurs in large masses, forming entire hills. No. 2 is a silicious dike rock, stained with iron oxide and copper carbonate. No. 3 is diorite-aphanite (a fine-grained black diorite). No. 4 is diorite. No. 5is an altered diorite, containing epidote, magnetite and pyrite (iron sulphide). No. 6 is mostly iron oxide, and is what is commonly called gossan. A shaft should be sunk on No. 6 to determine its character in depth.

The rocks from Hedley, B. C., are: No. 1 has the appearance of a silicified aplite. It is nearly all silica, with disseminated pyrite. No. 2 is somewhat decomposed. It is syenite. No. 3 is another silicified dike rock, similar to No. 1. No. 4 is similar, but contains more iron. No. 5 seemingly presents another phase of the same rock, while No. 6 seems to have come from a deeper part of the mine. It is not unlike the others in other respects. No. 7 may also be classed with the others. No. 8 is a fine, granular silica, with mispickel (arsenical iron sulphide). With the exception of No. 2, all of these rocks are evidently from the same district, and possibly from the same mass. They present various stages of alteration and variable amount of iron.

PITCHBLENDE, one of the ores of uranium, occurs, as a rule, in massive form, but occasionally is found in the crystallized condition, when it forms dark-brown translucent crystals. Its fracture is conchoidal to uneven, its hardness 5.5, while its specific gravity varies between 8 and 9.7. It, however, frequently occurs in altered form, and is partly or entirely changed by the effects of the atmosphere and moisture into the yellow hydrated oxide, whereby its specific gravity becomes lowered, and its color varied into canary-yellow or a somewhat darker reddish shade. Uraninite, when pure, is opaque, of a velvety-black or grayish appearance; has a submetallic, greasy, or pitch-like dull lustre, and gives a streak verging from brownish-black to grayish and olive-green. The metal uranium, or its carbide, has the peculiar capability of imparting desirable properties to iron and steel; imparts to glass a beautiful fluorescence of a greenish-yellow hue, and finds application in the manufacture of Welsbach mantels, being considered a welcome addition in cases to the thorium, cerium, and zerconium salts used.

SCREENS.—Screen aperture is of the first importance in describing any milling results, as it governs the size of the particles of crushed ore. It matters not what mesh screen is used, so long as we know *the size of the ores or apertures* in the screens, and, consequently, the maximum size of the ore particles issuing from any given screen. This is the precise information required, not alone in all comparisons of crushing results between various machines or mills, but also in that of chemical processes, where the relative fineness of the product submitted to solvents is of first importance.—P. Argall.

Mining Summary.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

Special Correspondence.

LONDON, February 14.

People of limited perspective imagined that the general election was going to have an adverse influence on trade. Such has not been the case, however. The cherished duty of heckling candidates for Parliament was not all-absorbing. The business of the country went on notwithstanding, as shown by the volume of imports and exports; in fact, January proved to be a record month in foreign trading, each side of the balance sheet showing an increase of some 5¾ millions sterling over the corresponding month of 1905. We bought from foreigners goods and raw material to the value of close on 12% more than in January of last year, and we sold 25% additional to customers outside the United Kingdom. The increase in exports included iron, steel and machinery, these important items particularly participating in the boom.

In other directions old John Bull is bent resolutely on proving that if he lacks the suppleness of youth, he possesses other qualities of a nature to command respect. He has just launched the *Dreadnought*, the most powerful, the best protected and fastest battleship afloat. Her displacement is 18,000 tons of water. Steam will be obtained from 18 Babcock & Wilcox water-tube boilers. She is boastfully described as combining the daring of the American engineer, the careful construction in detail and finish of the British workman, and the scientific thought which marks the products of the German General Staff. But John Bull is not to be allowed to spend all his surplus cash on munitions of war. The company promoter has opened the new year with attractions expected to secure a share of the nation's available funds. Rubber properties have been, perhaps, the leading favorites, but mining has not been lost sight of. A promotion which appeals more to the speculator than the investor is the Foldal Copper & Sulphur Co., Ltd., formed with a capital of £350,000, in £1 shares, to exploit a group of mines in Norway, covering an area of about 3,000 acres. Timber is available and there is an abundant supply of water to be obtained from the river close to the mines. The Foldal mine had been worked for a great many years, for copper only, but was shut down when the metal fell to a figure which left no profit. Three hundred thousand tons of copper-bearing iron pyrite were said to have been extracted by the ancients from a lode which they proved for a length of 200 meters and to a depth of 180 meters. Latterly this mine was unwatered for examination by that well-known authority on copper mining, M. Robellaz, of Paris. This gentleman in his report considers the Foldal mines to be "obviously in the same formation" as Roros, 55 miles distant, which has been worked for over 1,000 meters on the dip. Conditionally on this assumption, M. Robellaz estimates that 2,160,000 tons will be extracted to a depth of only 780 meters. When fully equipped, the mine will be capable of putting out 120,000 tons for many years, yielding a profit, with copper at £55 per ton, of £41,200. Another engineer estimates the profit at £68,700, or 11s. net per ton, judging from "developments upon other properties in Norway." In his report he "expresses the opinion" that the ore contains 2.25% copper, with 47% sulphur, and is practically free from arsenic. M. Robellaz states that his interpretation of the results obtained in the ancient workings "leads one to estimate" the average width of the mineralized mass at 3.75 meters; and he puts the ore in sight at 270,000 tons. The estimated net value of this appears to be about £100,000, and the mine is expected to begin profitable work in about two years. Before this desirable position is attained a ropeway must be built for a length of about 25 miles, from the mines to the nearest railway station. For all these prospective advantages set forth the company is to pay £224,000, of which £29,000 is cash. It is thought that an additional sum of £62,000 will suffice for equipment, as the ore will receive no treatment at the mine.

A mining flotation of an entirely different category is the Anantapur Gold Field, Ltd., with a capital of £30,000, the whole of which, with the exception of a few hundred pounds for purchase of options for two years on the property, and for the expenses of forming the company, is available as working capital. The area covered by the property is 2,447 acres, in the Anantapur district, Madras. The managers are Messrs. John Taylor & Sons, who have had the mining blocks examined by Mr. Thomas Richards, superintendent of Nundydroog and other mines. Favorable surface indications and ancient workings of a striking and extensive nature are to be seen, similar to those which led to the opening up of the great mines in the Mysore district. Quartz veins occur principally in chloritic and argillaceous schists. There are at least two parallel reefs—'true fissure veins.' In the event of the options being exercised, £3,000 is to be paid for the entire property, plus one-fifth in fully-paid shares of the nominal capital of a new and larger company. The promoters are content with 5% of the profits available for dividends.

In the Mysore district, the Champion Reef mine yielded a profit for the last financial year of £467,583 on a capital of £260,000 in 2s. 6d. shares. A pause—it is believed a temporary one only—has occurred in the brilliant success of this company. The lode maintains its width, but the ore has become poor, although some improvement is noticeable in the last fortnightly report. The January return was 17,222 oz. gold; mill yield, 15.55 dwt.; tailing yield, 2.59 dwt. Until the developments show normal values again, the milling is to be reduced by 3,000 tons per month.

As a proof that serious mining is going on in West Africa, the Abosso yield for January is cited. The 30-stamp mill crushed 3,889 tons for 2,563 oz., and 983 oz. were obtained from cyanide treatment. The new reef averages 3 oz. 7 dwt. for a width of 32 in., but further exploration and development are required to determine its extent. The list of a dozen producing mines in this colony totals up a return of about 18,400 oz. for January. The exceedingly adverse climate, according to one authority, accounts for the dilatory progress in West African mining, while from another quarter the health of the particular camp referred to is said to be in a most satisfactory state.

The gloom in South African affairs has been accentuated during the past week by the flooding, in consequence of heavy rains, of the Rudd shaft on South Rose Deep, causing the death of 55 natives, and by the suicide of a leading speculator in the Kaffir market. The contradictory Geduld assay-values also increased the prevailing depression. With the retort courteous (see my last week's letter), 'Westrallianism' is the term applied by a delineator of this new phase in South African mining. For the moment, a somewhat more hopeful tone is perceptible in Kaffir circles. The January output of gold from the Transvaal—428,638 oz., against 431,594 oz. in December—is considered satisfactory in view of the Chinese holidays.

A highly satisfactory report has been received from the consulting engineers of Esperanza (Mexico). The actual ore reserves amount to 127,400 metric tons, estimated to yield a net profit of $5,261,000 United States currency, not including ore capable of being won from probable reserves. The possibility of developing ore on the west vein system north of the fault, which traverses the property from east to west, is a feature of the report. Quartz 6 ft. thick, assaying $19.80 per metric ton, has been struck in a drill-hole. From this point to the boundary line there is an extent of 1,500 ft. of practically unexplored territory on the west vein system. Recent discoveries continue to open up extremely rich ore.

Messrs. Pearse, Kingston & Browne also write us under date of February 9: During the past week considerable interest has been evinced in Siberian mining, which may be a re-action from the deadly dullness which has lately over-shadowed everything Russian. It has its justification, however, in the good work being done at the Spassky copper and Nerchinsk gold mines. The latter company has just reported the fact that at their Kluchi mine the manager has succeeded in keeping his mills running up to date, since he started them for winter work in the middle of November. The significance of this report is apparent when one remembers that the average temperature in eastern Siberia during the mid-winter months is –70° F. The Kluchi is the first quartz mine to be operated in eastern Siberia. The Cabinet, who have hitherto controlled by far the greater part of Russian mining operations, have preferred to confine their attention to placer mining. Hence the Nerchinsk Co. has been doing pioneer work, and this winter's run has naturally been of the nature of an experiment, at any rate so far as the reduction works are concerned. With the question of winter work satisfactorily settled, and a body of ore 150 ft. wide going $12 per ton, this company should have a good future before it. Several registrations of new Siberian companies have been recently made, among which are the Sesan Syndicate and the Siberian Proprietary. The latter proposes to acquire a group of mines in the Orenburg district, which has been favorably reported on by Messrs. John Taylor & Sons, and which, worked by tributers with primitive appliances, has yielded 50,000 oz. gold within the past six years. It would seem, therefore, that Russia is coming into favor as a mining field.

It seems to be the opinion of engineers who have had an opportunity of studying Egypt that the water difficulty (at least in Upper Egypt) has been greatly exaggerated. No wells have been sunk for centuries, and as wadies with a profusion of mimosas are quite common, there is a probability that a good supply of water could be obtained if it were searched for systematically.

The South African market has declined lately. Various reasons are alleged, but there can be little doubt that the question of Chinese labor has been an important factor. It was so persistently used as a party cry during the general election, and so many exaggerated statements were made on both sides, that it has taken on a much more serious aspect than the facts of the case warrant. The new Liberal government may do its utmost to limit or stop the importation of Chinese; but the effects of such a policy are not likely to be so disastrous as the Tory party has seen fit to depict for electioneering purposes. There is a fair supply of Kaffir labor available, now that the demoralizing effects of the Boer war are wearing off; and this, with the contracts which have already been taken for Chinese, should prevent the labor difficulty from becoming a serious menace.

West Africans have taken an upward turn after a long period of depression. A curious side-light on this market is afforded by the fact that Bibiani shares stood at £1 premium twelve months ago, when the mine had not reached the producing stage. Now that it is earning about £10,000 per month, the shares are down to par, and have been considerably below.

DENVER, February 28.

From time to time rumors have circulated of 'finds' of gold ore in the low hills bounding the Animas valley, between Rockwood and Durango. Mr. M. T. Chestnut, of St. Louis, in passing through Denver recently, stated that he had found pay-ore of considerable width and exhibited samples showing free gold. Assays of some of the picked ore returned $200 and $300 gold per ton. Mr. Chestnut states that the ore came from a dike that can be traced for several miles. His locations are within sight of, and about one-half mile distant from, Trimble Springs, a station on the Silverton branch of the Denver & Rio Grande Railroad. Several men are employed developing the find.

The owners of the Iron Mask mine at Red Cliff are planning to erect a power plant, electric zinc separators and other facilities required for increasing the marketable output of that property. The Grand Junction Smelting Co. is considering increasing the capacity of the Grand Junction plant. The company has secured a lease of the Percy Chester mine at Red Cliff.

The Colorado Power & Irrigation Co. is establishing the grade of its water-power ditch. The ultimate intention of the company is to install an electric plant and distribute power to Leadville and other places. The present plans contemplate generating, with water as a prime power, 5,000 to 10,000 h.p. The Animas Power & Water Co. has continued active construction all through the unusually severe weather of the San Juan winter. The central power station is located at Rockwood on the Animas river, the transformer station being near the Silver Lake office above Silverton. The current is now transmitted to the transformer station and the company is prepared to supply power up to its full capicity. The water supply is from Cascade creek; the average capacity of the present reservoir being 1,000,000 cu. ft.; quantity, about 72 second-feet; head, 1,000 ft. With the present installation, the plant is capable of delivering 5,000 h.p. at the transformer station. Generators doubling this capacity are now being installed at Rockwood. The available water supply with additional development makes it possible to generate and deliver 30,000 h.p. to the transformer station. A high voltage, probably 40,000 volts, will be carried on the main line and a lower voltage on the distributing lines. The company has outlined a generous policy in dealing with the public. It will extend lateral lines one-half mile and furnish transformers to customers. The flat meter-rate is from 0.56 to 0.72 cent per kilo-watt hour; contract rates being from $60 to $78 per horsepower per annum. The minimum rate is based on 500 h.p., the maximum rate on 100 h.p. consumption.

Throughout the State there is a widespread movement to locate and utilize all the available water for power purposes. A score or more of companies are planning to use acquired water rights, while individuals, associations and companies are equipping reconnaissance parties to cover all parts of the State and locate unoccupied streams and sites. Irrigation and power possibilities that have been overlooked will be very scarce when the sun goes down on 1906, and defective title locations will be tied up with endless litigation.

Cripple Creek has an installed steam-boiler capacity of about 25,000 h.p. on the mines and producing power for mining operations only. On account of the large number of smaller properties working only at intervals, it is difficult to arrive at the exact percentage of power in use. A calculation made in April, 1905, showed that about 85% of the rated boiler capacity was in constant use. With three electro-power companies in the field, Cripple Creek uses about two per cent of electric power in mining operations. However, there is a growing tendency among operators buying heavier compressors, to provide a belt-wheel, and to have the air and steam-cylinders reversed, which is an intimation to the vendors of electric power that they are ready to be converted.

When the Rio Grande Railroad was extended to Silverton, it was more of an experiment than to handle the then existing traffic. For some years after its construction it was not a serious matter, to the road, that its trains were stopped weeks and even months at a time by snowslides. Today the case is different. The growing activity in the mines, calling for large quantities of machinery, building material and provisions, has during the past season taxed the road to its utmost capacity. The writer counted seven engines at one time shunting freight cars in the Rio Grande yards at Silverton last fall. Four 'double-header' incoming freights was a common daily occurrence. Notwithstanding the large number of engines and cars in service, the early snows caught Silverton a good many cars short, and when delivery was made the upper country was snowed in. Now the yards are full of freight that cannot be delivered until traffic is resumed above Silverton.

The Gold Prince mines have 67 carloads of freight in the yards.

It is reported that Silverton is to have another outlet by rail—that the Rio Grande is to extend its Creede branch to that point. What San Juan county and country needs most is a line that will give daily communication between mines and local supply points—some method that will go under or over or around the inevitable snowslide, and deliver the goods. An aerial ropeway, as now constructed, has its limitations. There is an opportunity for some engineer to gain renown and revenue by devising and building a system that will meet the conditions, here and elsewhere.

Until this is done there will always be difficulty in keeping a full force of men on the mines in winter and owners will continue to shut down early in the season rather than tie up thousands of dollars in supplies to carry them through the many months during which passage is difficult and often impossible.

SALT LAKE CITY, February 27.

Ore shipments from Park City last week reached a total of 4,073,180 pounds. The Daly-Judge Mining Co. took the lead in tonnage and sent out 1,148,000 pounds of ore and 386,000 pounds of zinc middlings. The Silver King sent 1,231,180 pounds; Daly-West 1,150,000 pounds; Keith-Kearns 128,000 and the Jupiter 30,000 pounds of crude ore and concentrates.

The East Ontario Mining Co., operating at Park City, will be officered during the coming year by E. M. Curtis, of St. Louis, as president; S. V. Derrah, of Salt Lake, vice-president; S. B. Schuyler, St. Louis, treasurer; P. R. Kingdon, Salt Lake, secretary, who, with J. H. Deiter, of Salt Lake, constitute the board of directors. Byron Hartwell, of Park City, is superintendent.

The May Asphaltum Mining Co., with headquarters at Myton, Utah, has been formed to operate asphaltum claims near Myton. George Lindsay is one of the principal shareholders.

The development of the St. Louis-Magnolia group at Park City is being pushed with a working force of 15 men. This mine is located in the center of the property operated by the Silver King Mining Co. Late last year James McGregor and associates, who are the owners, became convinced that the Silver King Co. had trespassed on their ground and extracted much high-grade ore. Representatives of McGregor gained entrance to

the Silver King workings to make sure that their suspicions were correct. Shortly afterward a demand was made on the management of the Silver King for a settlement for ore alleged to have been extracted. It is said the Silver King officials responded with a counter proposition, not satisfactory to the St. Louis-Magnolia owners, and after a little more parleying, further negotiations were cut off. The owners of the St. Louis-Magnolia concluded to sink a shaft on the ground and demonstrate that ore belonging to them had been unlawfully extracted. Late in December ground was cleared for the hoisting-plant, and in January the sinking of the shaft, now 80 feet deep, was begun. Some rich ore has already been encountered.

The nearest to definite information that has come to the public concerning the ambitions of Thomas F. Cole and F. Augustus Heinze to get a foothold in Utah mining camps came out a few days ago when it was discovered that Walter Fitch, former general manager of the United States Mining Co., is representing Cole et al. in this State, and for a number of weeks has been engaged in making examinations of some of the principal mines of Stockton, Tintic, Park City and Alta. The writer has learned that Mr. Fitch put in two weeks at the Columbus Consolidated mine at Alta, during which time an exhaustive examination of that mine was made. Following this, Mr. Fitch made the management an offer for a controlling interest, it is said, of $5 a share, which was refused. There is no longer any doubt in Salt Lake mining circles about Cole and Heinze having joined with J. A. Coram in the promotion of the American Consolidated Copper Co., the purpose of which is to control mines in Montana, the Bingham Consolidated and others in Utah, the Balaklalla in California, and presumably some of the copper producers of Arizona. In short, it is the purpose of the promoters to build up a mining and smelting institution as formidable as the United States Smelting, Refining & Mining and the American Smelting & Refining companies. Mr. Fitch has succeeded up to within the last few days in keeping his identity carefully concealed, and, in fact, the promoters of the scheme to enter the field as competitors of the last-named companies have done all in their power to keep their plans from the public.

The Honerine mine, at Stockton, looks like one of the coming big producers of Utah. The drain tunnel, which has been driving during the past three years, has been completed to 9,700 ft., and has proved the presence of ore in Honerine ground of a grade much higher than that taken out on the upper levels. A drift has been run on an orebody for nearly 100 ft., the face showing rich ore the whole distance. The width of the body has not been ascertained.

The St. Patrick Mining Co. has been organized to operate in Little Cottonwood district. D. A. Buck is president, B. A. M. Froiseth secretary and A. J. Smith treasurer—all of Salt Lake.

Ore and bullion settlements for the past week were reported by Salt Lake banks to the amount of $429,500.

The Last Chance mill in Bingham is being remodeled and will soon be placed in commission again. The Last Chance mine has, except for the operation of leasers, from time to time, been idle for a number of years. The property has been taken over by the Nevada-Utah Mines & Smelters Corporation, at the head of which is John Weir, of New York. This has also acquired extensive holdings at Pioche, Nevada, and the Comet copper property in Beaver county, Utah.

The Garfield Improvement Co., an auxilliary to the Garfield Smelting Co., has contracted for the erection of 90 buildings in the new smelter and mill town of Garfield, which has been laid out 15 miles west from Salt Lake City. The buildings are to consist of a large boarding-house, bath-house, club houses and dwellings, enough to furnish accomadations for a population of 500. The new town will have modern conveniences. The Garfield Water Co., another auxiliary will expend a quarter of a million dollars in the building of a system to supply water, not only to the town, but to the smelter. A concrete flume, 8½ miles long, will bring the water to the town. The mills of the Utah Copper Co., now under construction, and the proposed Boston Consolidated plant, will be located near the town. The San Pedro, Los Angeles & Salt Lake and the Western Pacific railroads will run their main lines near it, and the Rio Grande Western will come in via Bingham Junction.

At the Garfield smelter the work of construction is progressing rapidly, and the company has already broken all previous records. The 300-foot stack is finished and the flues, which are to be 2,300 feet long.

What appears to be an important strike in the Uncle Sam Consolidated mine, in the Tintic district, was made a few days ago in a winze sunk from the 500 level. The ore is of high grade.

H. M. Crowther, manager of the Continental-Alta mines at Alta, with headquarters at Salt Lake City, has secured a ten years' lease on the right of way of the Rio Grande Western from Bingham Junction to Wasatch, and the old tramway grade, owned by the same company, from Wasatch to Alta. Mr. Crowther and associates will form a corporation to be known as the Continental Transportation Co., and will construct a standard gauge road from Bingham to Wasatch this year, and may re-build the tramway to Alta; yet the latter may not be undertaken until next year. The result will be to cheapen the cost of marketing ore from Alta mines. The camp will be put on an equal basis with Park City in the way of transportation, which is from $1,50 to $2.50 per ton.

The ore shipments from the Tintic district last week aggregated 175 carloads, the shippers being: Ridge & Valley, 7; Gemini, 16; Centennial-Eureka, 51; Bullion-Beck, 9; Dragon Iron, 15; Brooklyn Consolidated, 3; Beck Tunnel, 7; Uncle Sam Consolidated, 5; Eagle & Blue Bell, 6; Swansea, 4; Eureka-Hill, 15; Yankee Consolidated, 2; Ajax, 5; May Day, 1; Black Jack, 4; Carisa, 4; Lower Mammoth, 1; Mammoth, 15; Victor, 1; Uncle Sam (concentrate), 2.

The Boston Consolidated Mining Co. has commenced grading for two miles of standard-gauge railroad to connect the portion of its property on which steam-shovel mining is to be inaugurated with the Copper Belt Railroad. The Rio Grande Western, which owns the Copper Belt, is also going to commence the construction of another line into Bingham, penetrating the Carr Fork section of the camp, and ending near the Highland Boy mine of the Utah Consolidated Mining company.

The management of the Utah Copper Co. will award contracts for the equipment of the concentrating mill, now in course of construction near Garfield, within another week.

BUTTE, February 24.

The Butte men interested in the new mining companies being organized in New Jersey and New York are in the East, and there is little information obtainable in Butte. The directors mentioned for the Butte Coalition, the $15,000,000 corporation organized under the laws of New Jersey, are unknown in Butte, but the directors of the Red Metal Mining Co., a $11,000,000 corporation organized under the New York laws, are mostly Butte men. W. D. Thornton is one of the large stockholders of North Butte. John C. Lalor is manager of the Daly estate, and Roy S. Alley is private secretary to John D. Ryan. The objects of the organizations are unknown here, but it is surmised that they are both Cole-Ryan companies, formed to take in the United Copper, North Butte, Clark, and other mining companies, and aiming for a general combination of Butte mining concerns.

Nearly a score of new companies have been organized in the last six months to work Butte copper mines and undeveloped claims. They include the East Butte, the Butte & Columbus, the West Butte, the Butte & St. Louis, American Consolidated Mining Co., the Butte & London, the Butte Copper Exploration Co., the Butte Coalition Co., Red Metal Mining Co., the Butte-Montana, and others, among the more important companies. The Lewisohns of New York have options on the Amazon group, in the southeastern portion of the Butte district, and under the direction of J. Parke Channing the properties are being opened and examined. In the group are several mines owned by Henry Brundy, from which for a number of years he has taken rich copper ore from near the surface. Many masses of native copper have been taken out of the workings, but the ore has been in spots and pockets.

The Butte Copper Exploration Co. is pumping the water from the shaft on the Six O'clock mine and will begin sinking the shaft deeper.

The Butte & London Copper Mining Co., which owns 113 acres of ground about 1,000 ft. east of the North Butte company's ground, is making rapid progress in sinking a shaft, which in a few weeks has reached a depth of 100 ft. Machinery for a hoisting plant is on the ground and will soon be installed.

New York capitalists have become interested in the old Ophir mine, lying in the southwestern part of the city, and arrangements are being made to explore the property for copper. It has produced a lot of silver in years past, but for some years it has not paid operating expenses. The shaft on the Ophir is 300 ft. deep and the new parties interested in the mine will try to find copper at a depth of 1,000. There has so far been little or no indication of copper in the mine.

Chicago men have taken an option on the Sunbury mine, one of the small properties in the East Butte section, and will soon begin explorations in it. Leasers have been working the Sunbury for copper and have mined considerable from a small vein. Their interests in the property have been purchased.

The Raven Copper Mining Co. will soon cut the Snoozer vein at a depth of 1,500 ft., and undoubtedly a large body of ore will be opened. On the 1,200-ft. level the drifts east and west have been driven in ore and the east raise has opened a body of black copper ore averaging 12% copper. The face of the east drift is in copper glance. The west raises are in ore similar to the ore in the east raises. From the east drift a crosscut has been run south and another vein, eight feet wide, has been cut.

The Reins Copper Co. is still sinking the shaft on the Combination mine. It has reached a depth of 1,080 ft. and will go 120 ft. deeper, and from that point crosscutting will be done. Next to the shaft on the Emma mine, the Reins has been the most expensive piece of mining ever done in the Butte district, owing to the bad character of the ground and immense inflow of water.

ARIZONA.

Cochise County.

A 100-ton concentrator is being installed on the Cochise Consolidated mine, near Paradise. The mill will be driven by a gasoline engine and the hoist and pumps at the mine will be operated by electricity. The plant is being erected under the management of C. S. Hagan.——The owners of the Henkel-Taylor group, near Paradise, have arranged to extend the main tunnel on the Senator claim 250 ft. to cut the main ledge.

The owners of the Shattuck and Arizona mine, at Bisbee, are receiving bids for work on the new tramway to connect the mine with the railroad, and for an air compressor. Contracts are expected to be let within a few days. A large hoist for the Shattuck mine is now on the way from the East. On the 700-ft. level crosscut No. 1 has passed through the sulphide orebody and is in oxidized ore. Work is about to begin on the enlargement of the main shaft, and raises will be started from the 300, 500 and 800-ft. levels.——The management of the King Lead mine, near Paradise, has decided that no more chloriding will be done at this property for the time being. Development will be continued.

The Saratoga Mining Co. has contracted for sinking the shaft at the Saratoga mine, near Douglas.

Gila County.

On February 20 fire broke out at the ninth level of the Interloper shaft in the Old Dominion mine. Three men lost their lives in an endeavor to put out the fire. The efforts of the management have since been devoted to bulkheading the connections between the burning shaft and the mine. All levels have been closed except the 10th and 12th, and the latter has been flooded. The 10th level will be closed as soon as possible.

Maricopa County.

The Blue Bird mine, 16 miles north of Phœnix, has been re-timbered and development work has been resumed on the 300-ft. level.

A new hoist has been put in at the Mormon Girl mine, on Cave creek, and a new air-drill will be added.——The Oro Grande Mining Co. is arranging to prospect the lower levels of the Oro Grande mine, near Wickenburg, with diamond drills.

Mohave County.

The German-American Mining Co. is installing a compressor on its property in the San Francisco district, 12 miles east of Needles, Cal. Air-drills will be placed in operation on the Thirty-fifth Parallel and Treadwell mines. The management of the company has decided to adopt the leasing system on all of its property, except the Thirty-fifth Parallel and the Treadwell.——S. Fields, of the Arizona-Mexico Mining & Smelting Co., is putting in a concentrating mill on the company's property at Stockton Hill, near Kingman.——The New Comstock Con. Co. is unwatering the Boulevard mine, at Union Pass, 30 miles northwest of Kingman. A drift is to be driven to the ore-shoot from the 200-ft. level.——N. M. & J. D. Richardson are driving a crosscut to cut the vein on their property at Union Pass, near Kingman.——J. H. Hoffman, of the Chloride Gold Mining Co., is sinking a shaft on the company's property at Chloride. The shaft will be carried to the 500-ft. level. The owners of the Enterprise mine, near Kingman, have decided to sink the shaft several hundred feet below the present level and to install a plant later in the year.——The Cerbat Mountain Mining Co. is to put in a concentrating plant at the Vanderbilt mine, near Kingman.——The San Diego Gold Mining & Milling Co., of San Diego, Cal., has contracted for the sinking of the main shaft on their mines near Union Pass, 29 miles west of Kingman.

Pima County.

Both furnaces of the Cieneguita Copper Co.'s smelter, near Tucson, are to be started up during the coming week. A calciner is also completed and the shipping of matte is to begin early in March.——The smelter at the Helvetia mine, near Tucson, will be started up within a few days.

Yavapai County.

(Special Correspondence).—The Yaeger Canyon Copper mine, located near Prescott, is making regular shipments of high-grade ore and concentrates to the Arizona Smelting Co. of Humboldt. The property has been under the general superintendency of Chas. E. Bunker for the past two years.

Prescott, March 1.

W. F. deCamp is unwatering the Richinbar mines, at Mayer, below the 400-ft. level, and will open the property at the 500-ft. level.

The Esmeralda Mining Co. is installing new hoisting machinery on the Cornucopia mine, at Ash Creek, near Dewey, and sinking will be resumed.

The Golden Idol Mining Co. is arranging to put in machinery and open up the Dick Lyons group, near Cherry, to greater depth.——The Arizona Gold Lodes Co. is putting in a tramway to connect its mills and mines, 16 miles east of Dewey.——The Buffalo Lime Cap Mining Co., of Cherry, will continue its tunnel, now in 1,800 ft., 200 ft. farther to tap the veins opened on the surface. Power drills are now being used. ——The Federal Mining Co., which suspended operations some time ago, is preparing to resume work at its mines, near Cherry.——W. R. Allen is sinking a shaft on a newly discovered prospect, near Cherry——The owners of the Mocking Bird mine, near Weaver, have let a contract to sink their well to a depth of 130 ft. A whim is to be put in. A mill will be erected as soon as a sufficient water supply can be secured.——T. J. Carrigan has let a contract for extensive crosscutting on his property, near Prescott. The crosscut will tap the mountain at a depth of 420 ft. He is planning a 20-stamp mill.——E. S. Campbell, of the Surprise mine, near Poland, has contracted for the extension of his tunnel several hundred feet, and is preparing to build a tramway from the mouth of the tunnel to the railroad station at Poland. ——The owners of the Apache-Panther mine, at Harrington, are building a wagon road from Crown King to the mine. A hoist is to be installed in the near future. ——The Lynx Creek Gold Co., owning 18 quartz and placer claims on Lynx creek, five and one-half miles east of Prescott, is to put in a 200-ton plant.——The main shaft of the Chancellor mine, near Prescott, will be sunk 100 ft. farther before beginning to crosscut.

CALIFORNIA.

Amador County.

At the South Eureka the new electric pump, with a lift of over 1,800 ft., has been in successful operation at the mine for the past two weeks, handling most of the water from the Central and South Eureka.——R. Kimball is reported to have found a gold pocket in the Dead Sheep mine, near Defender.——In the Kennedy, at Jackson, they are drifting at the 2,850 level to the west or foot-wall ledge. The 100 stamps are in operation.

El Dorado County.

A compressor and machine drills have been installed at the Cedar Creek mine, near Fair Play.

Kern County.

The Little Butte Mining & Milling Co., at Randsburg, has leased to C. S. Taylor and H. J. Giadoni the Little Butte mines.

Mariposa County.

The new owners of the Three Tree mine, five miles from Hornitos, have completed the electrical equipment of the mine. It is announced that new machinery will be put in.

Mono County.

E. S. Smith has taken a bond on the Con. Pacific, owned by T. Colligan; the Midnight and Flagstaff, owned by T. and J. S. Cain, and the New Standard, owned by Mrs. Belmont and John Long. The bond requires that $12,000 worth of work be done within four months. All these mines are in the Masonic district,

near Bridgeport.——T. V. Whitelaw will commence active operations on the True Friend group, at Masonic.

S. Cavanaugh, lessee of the Ward mine at Castle Peak, near Bridgeport, has suspended operations on account of the heavy fall of snow.——A tunnel is to be run from the lower canyon to cut the main ledge of the Julia & Myrtle mine at Lorena, near Bridgeport.

Nevada County.

The new pump for the Ironclad mine, near Grass Valley, has been installed.——E. F. Hilton and F. Page of San Francisco, and A. Taft of Kansas City, have bought the Morayanda mine, near Newtown.——The Union Hill Consolidated Mines Co. will hold a stockholders' meeting on March 10 to consider the disposal of its property.

S. H. Dille has sold his 10-stamp mill, at Dutch Flat, to the Ironclad Mining Co., and it will be moved to the Ironclad mine at Rough and Ready.

Plumas County.

John Chamberlain and William Brown, of Cascade valley, are in San Francisco arranging for machinery for their quartz mine near Cascade Valley, on the line between Butte and Plumas counties.

San Bernardino County.

L. A. Milligan has sold five claims near Barstow to Henry Mountain and William Schell of New York for $22,500.

The sampling plant at the Needles smelter is being installed this week by the Arizona-Mexican Mining & Smelting Co.——The reported discovery of rich ore by C. H. McClure, 15 miles south of Needles, has resulted in a large amount of prospecting in that locality. A new town, known as McClureville, has sprung up about the McClure claim.

San Luis Obispo County.

The Silver Swan mine, near Cayucas, has been sold by I. Holt and R. L. Dempsey to S. Clark.

Shasta County.

The Mammoth Co. is preparing to prospect extensively near the surface on its orebody near Kennett, by means of diamond drills.——Charles Dozier is installing a 25-ton cyanide plant at the National mine, four miles south of Kennett.

It is reported that silicious gold ores will be shipped from southern Oregon to the smelter of the Mammoth Copper Co. at Kennett. The Mammoth ore runs usually about 10% silica, 35% iron, 45% sulphur, $3 gold and 5% copper. The coke used is shipped round the Horn from Belgium. Tests of Washington coke are being made. ——It is reported that another smelting plant will be erected in Shasta county. The owners of the Balaklala mine are clearing ground for reduction works. It is said that they will build reverberatory furnaces to be fired with oil, mechanical roasters and converters.

Fourteen miners and helpers were added to the force of the Mammoth mine, near Kennett, this week.

The Mountain Monarch Gold Mining Co. has begun operations five miles west of Shasta. An aerial tramway is now being built from the mine to the millsite. The company is figuring on a cyanide plant.——The Mammoth mine, in the Old Diggings district, near Redding, is to be developed by G. Hurst, of Redding, and J. M. Sweeney, of Detroit. Mr. Hurst is arranging for extensive development at the Iron Mountain mine, at Iron Mountain, near Redding.——Engineer White, of Salt Lake City, is now at Kennett looking over the ground for the proposed smelter for the Balaklala mine. ——The third furnace of the Mammoth Co., Kennett, is practically completed, and will be blown in during the next few days. A new motor-generator was placed in the power-house this week and the new compressor and drills at the mines began operations a few days ago.—— The Farontul and Gopher claims at Madox gulch, near Kennett, have been bonded to N. W. Keith, who began development this week.——A bag house is to be provided at the After Thought mine, near Bella Vista, to save the zinc in the form of zinc oxide.

Sierra County.

(Special Correspondence).—The machinery for the electric power plant at the Tightner mine is being installed.——The Alaska mine, at Pike City, recently tapped the shaft with a drain tunnel.——The Rainbow mill, at Alleghany, is running on fair grade rock.—— The King Con. group, in Keystone ravine, owned by J. Hayes, L. Flint and others, has been bonded to San Jose parties, who will begin development.——Work is progressing on the drain tunnel at the Marguerite.—— Turney, Flint & Nickols have struck a good prospect in the gravel below the mouth of Ladies Canyon.——Good ore is being mined at the Sovereign.——The Empire has the electric plant about ready to run again.——The Last Resort is up 25 ft. with their raise, in good ore.—— F. C. Le Blond, one of the principal owners of the Hilo, arrived this week. They have plenty of water to wash gravel and are washing up their dump.——Spaulding & Peckwith have water and are washing good gravel.—— The White Bear has a large crew breasting.——P. H. Mason, superintendent of the Golden Scepter, reports work favorably progressing at the mine.——The Telegraph is closed down temporarily, owing to the electric pump not working satisfactorily.——J. S. Wallace, superintendent of the Antlers, reports the tunnel nearly into the ledge.

Downieville, Feb. 24.

Siskiyou County.

The Freshour Bar claim, at Gottville, has been pumped out and work has been renewed in the bedrock gravel.——The Blue Gravel mine, at Greenhorn, near Yreka, is being opened up by sinking a new shaft and drifting along bedrock. The pumps have been taken out of the old shaft and will be put in operation again. The Pine Grove placer claim, at Oak Bar, near Yreka, is being opened up. A hydraulic elevator will be installed early next month.

The owners of the Hamilton mine, at Oro Fino, have ordered machinery and will sink a perpendicular shaft 200 ft. A mill has been ordered.

Trinity County.

The Trinity Copper Co., of which Thomas Lawson is president, has a large force at work on the Shasta King mine and will also build smelting works.

Tuolumne County.

Two men were badly injured by the premature explosion of a blast, on February 24, at the Blackhawk mine, near Soulsbyville. The men were ascending the shaft after having spitted the fuses.——H. H. Cloud has bought the Esmeralda mine at Second Garote, from C. W. Sheridan, and will continue its development.

COLORADO.

(Special Correspondence.)—A late report is to the effect that several miners had erected a small mill outside the Cripple Creek district for the purpose of treating the high-grade material which they had secured from mines in the district. The men were arrested charged with 'high-grading.' Efforts are being made by the operators to stop the wholesale stealing of the high-grade ore from the mines. It has been impossible to convict parties charged with high-grading heretofore even though the owner of the ore identified same as being his own. Heretofore it has been the custom of the ore thieves to dispose of the booty to assayers, either in the district or others dealing in that class of material, receiving from 25 to 50% of the value of the ore. If the purchaser found that the party was afraid of being caught with the goods the percentage would not be as high. A number of assayers have been run out of the district who it was claimed were acting as a 'fence' for the ore thieves.

The new railroad contemplated to run from Ft. Collins, about 75 miles north from Denver, through Wyoming, will open up a large tract of country hitherto practically undeveloped. Incorporation papers have been filed with the Secretary of State.

It is understood that Gov. McDonald will be called upon shortly to make a thorough investigation of the explosion in the coal mine of the Victor Fuel Co. in the Maitland district whereby several men lost their lives.

A number of labor organizations of this State have recently passed resolutions condemning the actions of the Idaho and Colorado authorities in arresting and taking to Idaho from Colorado the head officials of the Western Federation of Miners. The officials who were arrested about one week ago are said to be implicated with Harry Orchard, under arrest, in the murder of ex-Gov. Steunenberg of Idaho. They are in jail in Idaho awaiting trial. Some of the unions are reported as having subscribed several thousand dollars to the fund for the defense of the men arrested.

If good weather continues in the mountains it will not be many weeks before the placer mines commence operations. It is reported by a prominent engineer who has been in charge of large placer properties the past year, that snow in the mountains above Alma and Breckenridge is not as plentiful as a year ago, yet it is in better condition as it has drifted into the gulches and timber and is well protected. In many of the gulches it is practically solid ice which means it will be a long time in thawing out and much better for placer work. The placer interests of the State are becoming extensive and this year will see much activity, especially in Park and Summit counties.

Denver, Feb. 26.

Fremont County.

The prospective electric road from Canon City through Eight-mile park to the top of the Royal Gorge is interesting mining men. It is eight miles from Canon City, yet the inaccessibility of this region has prevented any extensive development of its mineral wealth. In 1900 E. E. Smith located 200 acres of mineral land near the gorge and has done some developing. Garnets, sapphires and green and pink tourmalines have been found, and on the claims in quantity are the ores of tantalum, tantalite and columbite. Tantalum is now in demand for use as filaments in incandescent electric lights. Samples of ore sent by Mr. Smith to Bremen, Germany, for analysis show a range of from 20 to 74% of tantalum pentoxide. The ore is found here in placer deposits and in leads of white quartz. About 1,000 lb. of the ore have been taken from the claims and development has been only begun.

Ouray County.

(Special Correspondence).—The Barstow Mining & Milling Co., operating the Barstow mine, near Ironton, along with other improvements, will instal another large air compressor, an electrically-driven pump and is considering a first-motion hoist. The mine development work of the past year has opened large shoots of good grade milling gold ore. The recent strike of ore on the Mineral Farm, near Ouray, is leading to a more thorough prospecting of the contact area in that vicinity. Heretofore bodies of ore have been found in that so-called gold belt which have yielded large and permanent profits to the owners, who extracted the ore and shut down the mine.

Ouray, Feb. 24.

Among the mining enterprises in the Red Mountain and Ironton districts is the Continental Smelting & Refining Co. The old Saratoga mill is now owned by this company, and a large amount of money is being expended putting it in shape in order to handle the low-grade ores, of which there is a large quantity in these districts. Already two furnaces have been purchased, one being in place. As soon as the weather improves, work on the smelter will be resumed and the second furnace installed. The company holds under lease a quarter section of land, which includes the Comstock, Vest, Saratoga and others. These can supply the smelter with ores for at least 20 months. Many properties in the same territory not controlled by the company have low-grade ores which can be obtained. The principal properties are the Ironsides, Gibson-Dutton and the Yorktown group. The Mono-Baltic is said to have 40,000 tons of ore blocked out and is only a short distance from the smelter. A large tunnel is planned and will be commenced in the spring. The ore in the Saratoga lies in a blanket vein and is silicious iron oxide, 20 ft. thick in many places. The silver averages from 6 to 25 oz. There is also in the Saratoga a rhodonite vein carrying from 8 to 10% copper.

A citizens' committee has been formed at Ouray, to find ways and means to prospect the limestone and other formations beneath the town. This is to be done by means of the diamond drill.

IDAHO.

The report of State Mine Inspector Robert N. Bell for 1905, recently issued, states that in the mining industry in that State 6,000 men are employed, of whom about 3,000 are in the Cœur d'Alene. The total number of fatal accidents reported from all causes was 20, as compared with 10 during 1904, for approximately the same number of employes. The causes of these fatalities were the following:

Explosion of blasting compounds	5
Falls of rock	5
Falling down chutes	3
In moving of cage	2
Contact with trolley wires	2
Moving car	1
Caving of ground in placer mine	1
Gasoline tank explosion	1
	20

Each of these accidents happened singly to the unfortunates, except in one instance where two men were killed by a fall of rock. The Inspector expresses the opinion that the most of these accidents resulted from the personal carelessness of the men.

Boise County.

E. F. Blain, of Placerville, states that he will get his dredge started about March 1.——Dr. Fairchild and associates will run a tunnel about 4,000 ft. long to cut a system of ledges at the head of Boyle gulch, near Placerville. They expect to tap the main ledge at a depth of 1,000 feet.

Idaho County.

Harry J. Cone is planning to put in a reduction plant at his mine, near Elk City. He is at present watching experiments of the Idaho Reduction Co., at Lewiston, upon the result of which his future course will be based.

Kootenai County.

Extensive operations will soon be commenced on the Port Arthur mine, near Sand Point.

Nez Perces County.

The Gateway Mining & Milling Co. is arranging to build a five-stamp mill on its property, near Pierce.—— The owners of the Ozark mine, near Pierce, will replace the present rocker mill with a five-stamp mill.——All of the flats near and on Orofino creek, near Pierce, have been sold for dredging.

Shoshone County.

A second tunnel, to run 1,100 ft., which will intersect the vein at a depth of 500 ft., has been started by the St. Louis-Idaho Mining Co. on its claims, near Burke. ——Theodore Anderson, of the Rex mine, near Wallace, will begin operations at the mine within a few days. The machinery at the mill is now being overhauled and put in shape.——The new crosscut tunnel at the Yorktown mine, near Osburn, has cut the vein at a depth of over 300 ft. from the surface. A drift has been started toward the Blue Grouse property.——The Mineral Point mine, near Osburn, is crosscutting its ledge 400 ft. below the old workings.——The owners of the Surprise mine have completed the first 100 ft. of the proposed 400-ft. crosscut tunnel.——Charles H. Dow and Ralph Woodworth, of Boston, have completed the purchase of the Amzel Samuels and Mrs. H. C. Bickerton interests in the Hercules mine for $62,500.——The Alhambra Mining & Milling Co. have struck the foot-wall of the vein on its mine, near Wardner, and is drifting. The main tunnel is in 1,400 feet.

Clearing of the 1,400-ft. shaft at the Frisco mine, four miles from Wallace, has reached the 500 level. It will require three months to put the mine in shape. When operations are resumed the mill will be equipped to save the zinc in the ore.

Washington County.

The Hancock Copper Mines Co., Ltd., is arranging for the erection of a plant, near Landore, to operate under the Dewey process. The machinery will not be purchased until after the return of C. F. Drake, manager to the company, from Boston.——G. Sperling engineer for the Syndicate Mining, Milling & Smelting Co., of Weiser, has completed a survey of the company's mine.

MONTANA.

Jefferson County.

The owners of the Blue Bird mine, near Wickes, are opening up and re-timbering the main tunnel.

Lewis and Clark County.

Lessees of the Helena mine, at Helena, struck a new vein while drifting on the original lead at a depth of 150 ft. —— M. W. Alderson has secured an option on the Goudy claims, near Austin, and will proceed with development.

Silver Bow County.

The compressor and electric pumps for the Lexington mine, at Butte, are on the ground, but no movement has been made toward installing them. —— The Columbus-Butte Co. has begun work on its 1,200-ft. shaft on the La Monte claim. —— The Butte cyaniding plant at Centerville has suspended operations.——The owners of the Reins mine, at Butte, will sink the shaft an additional 120 ft. and crosscut.

The Gagnon mine at Butte has been closed down to retimber the shaft between the 1,000-ft. and 1,300-ft. stations. The mine will be closed for about six weeks.—— The Never Sweat mine at Butte has re-timbered the shaft between the 200 and 650-ft. levels, and has resumed operations.

Yellowstone County.

M. J. Bergin, president of the Columbus-Butte Mining Co., is considering equipment of the company's mine at Columbus with heavier hoisting machinery, and sinking the shaft to 1,200 feet.

NEVADA.

Esmeralda County.

The hoist of the Nevada-Goldfield mine was put in operation on February 16. Sinking has been resumed on the 100-ft. shaft, which will go to a depth of 500 ft. before crosscutting.——Kenneth Wade has engineers surveying the Lucky Strike property, near Lida, preparatory to active operations.

The Montezuma Co. has adopted the leasing system at its mines and claims at Montezuma and has already given year leases on the Arizona, Bullion, Benton and Caraccas properties.

Louis Stevens has hauled the boilers, air compressors, drills and other machinery to the American Nickel Co.'s mines at Cottonwood, and has been given a contract to furnish 400 cords of wood for that company. A new hoist is expected to arrive at Lovelock for this company, which is developing the Nickel and Cobalt mines.

Frank Helm, of Goldfield, is at Manhattan, arranging for the construction of a mill for the Oddie-Gardner Co., of Goldfield.

C. Kaufman and J. J. Hall, of Corning, Cal., and G. Kraft, of Oroville, Cal., have taken a lease on the Florence, near Goldfield, and have purchased a gasoline hoist, boiler and whim. —— On the Gaston lease, at the Atlanta mine near Goldfield, a crosscut has been started at a depth of 160 ft. from the working shaft. —— Ore-bins are being built and a new hoist erected at the Great Bend mine, near Goldfield. —— The new shaft at the Adams mine cut a body of low-grade ore this week at 75 ft. Sinking is to be continued. —— The Goldfield Northern Mining Co. has begun work on its property, four miles north of Diamondfield. —— The Lida Queen Mining Co. has decided to let leases on its claims at Palmetto, near Goldfield, except the Fortunis and Buster claims.

Elko County.

The 60-ton smelter of Gage & Turner, at Mineral Hill, was started up on Feb. 17. Mr. Gage is preparing to put in a smaller plant at the Sutherland antimony mine, 14 miles east of Lovelock.

John Green has struck a ledge of gold ore in the Bullion district. The ore is white quartz.

Humboldt County.

Henry W. Kent is opening up a group of claims in the Dun Glen district near Winnemucca.

Lincoln County.

(Special Correspondence).—The electric plant at the Quartette mine is being enlarged. They are also installing a compressor and a 100-h. p. engine and increase the voltage to 60 kw. The present equipment consists of a 35-kw. dynamo, driven by a 40-h. p. gas-engine.

Superintendent Rose, of the Southern Nevada mine, has a large force at work on the Blossom crosscutting, drifting, sinking and timbering. The shaft is down 430 ft., and on the Goodenough adjoining they are drifting east and west on the 110-ft. level.

At the Duplex they are doing considerable crosscutting to connect with the two veins. Superintendent Barnes is also developing the Fraction, New Year's Gift and the Good Hope mine, on the latter being down 600 ft., with several crosscuts to the vein.

Owing to the large flow of water developed on the Pompeii, work has been suspended except on the new shaft 100 ft. west of the main shaft. A new pump of 500,000 gal. daily capacity is to be installed, after which work will be resumed. A strike of rich ore was made on this property at the 262-ft. level. It shows three feet of ore, said to average $300 per ton.

Searchlight Mining & Milling Co. report having struck a large body of high-grade ore at a depth of 250 ft. The ore runs from $60 to $220 per ton.

Camp Sunrise reports a big strike by Halquist & Hummel, the original locators. On the Estrella claim they uncovered two veins close together. F. W. Holmes, George Morrison and C. R. Topping have taken up five claims and are working them.

El Dorado canyon reports a strike on the Silver Legion. At a depth of 120 ft., while sinking through a granite wall, they encountered a ledge of quartz that runs $600 per ton in gold and silver. Some fine specimens were brought in and sacking is to begin for a trial shipment.

Three miles north of Searchlight, just outside the mineral belt, the Oregon group, now being developed by the Searchlight Consolidated Co., at a depth of 70 ft. opened up a two-foot ledge that averages $180 per ton. The ledge has been exposed at intervals, but the ore has been mostly low grade. Contract has been let to sink the shaft to 500 feet.

The Cyrus Noble have started their 10-stamp mill and are milling 40 tons per day. They have 800 tons on the dump. Superintendent Luxon is enlarging, timbering and improving the shaft, and constructing a new building for the electrical plant to be installed. Some good ore has been found in the lower levels while drifting the past week.

Too much water is the report from the Santa Fe and the Big Six mining companies. On the former, at the 200 level, the water has more than doubled until there are now 10,000 gal. The Big Six has struck a small flow of water, which is increasing as they go down, and a pump will be installed.

Surveys have been made for the pipe-line from the Pompeii mine to the town of Searchlight, a corporation having been formed to build reservoirs and supply the town with water for domestic use and the mines for milling.

The Mountain group, in El Dorado canyon, has been bonded by C. L. Gresh and E. J. Roberts for $50,000 from Gennes & Copp. They are acting for several Pittsburg capitalists, who are also heavily interested in the Venus, Black Hawk and El Dorado properties. They have a shaft down 125 ft., and everything pans. A large force is at work, and a 15-h. p. hoist is on the way. Superintendent Gresh, of the Black Hawk mine, reports that the 10-stamp mill now being constructed will begin operations on March 15. The Combination group, 2,800 ft. from the Black Hawk, has been bonded to a syndicate of San Francisco men.

Searchlight will soon be illuminated by electricity, as plans for the power-house are drawn and the contract to build will be let as soon as all the specifications are completed.

James Portalis, of Austria, who is interested in Colorado mines, has purchased one-half interest in the Duplex and Good Hope mines at Searchlight.

Searchlight, Feb. 24.

(Special Correspondence)—Again is Pioche promised a railroad. This time the San Pedro, Los Angeles & Salt Lake Railroad gives positive assurance of an early connection between Caliente and Pioche. The grade has been made and is in good condition. In anticipation of its completion and coincident with the recent advance in the price of silver, a number of abandoned mines are now being re-opened. First of these are the old Raymond-Ely and Meadow Valley, now being worked by the Nevada-Utah Mines & Smelters Corporation. This company has repaired the old hoists and is retimbering the Meadow Valley No. 5 shaft, on the east end of their property. This has three compartments and is down 1,400 ft. on the incline. Pumps are to be put in and work started below water level, in hope of developing a continuation of the rich orebodies above. A crosscut is also being run to tap the Yuba-Mazeppa vein. At the west end of its property the company purposes to work the Raymond-Ely vein and the Black Ledge through the No. 1 shaft to the 1,200-ft. level. Contracts are to be let for an electric power plant to furnish current for the hoists and pumps. The Day mine, at Jack Rabbit, is being worked by the same company, who have re-constructed the railway to Pioche and are running ore trains. An aerial tram is being built from the Day to the railroad terminus and large ore-bins have been finished. Electric power is to be transmitted to the Day from Pioche. It is as yet undecided whether to start the smelter at Pioche or to ship ores to Salt Lake City. Geo. F. Milligan is engineer in charge.——Godbe Bros., of Salt Lake City, propose to start extensive operations on their properties adjoining those of the Nevada-Utah Co. They are also prepared to treat the tailings pile at Bullionville. Cone classifiers will be put in to separate the sands and slimes. The sands will be treated by fine grinding in tube-mills and agitation and cyanidation in the Godbe agitators. The slimes, which carry values in lead, will be filter-pressed and either shipped or smelted at the mine.——The properties owned by Simon Bamberger and J. D. Wood have been patented and it is reported that work is to be started soon.——Arbogast & Mulhall are working gold mines two miles east of Pioche. ——The Yuba-East case was decided in favor of A. W. McEwen, but has been appealed by Lloyd & Cook, who are said to have taken out $5,000 in one month's work. ——The Boss claim, near Pioche, has been bought by Miller and associates, of Boston, who intend sinking a working shaft. E. P. Gordon has charge at the mine. ——A. W. Scott and E. H. Sheu, of Salt Lake City, are working 2½ miles west of Pioche, on a manganese-gold mine, which they have under option.——The Advance Mining Co., D. J. Lawrence president, is shipping ore from the Chief district, between Caliente and Pioche. ——Considerable work has been done by Lloyd, Cook & Osborn on the Mendah mine, seven miles west of Pioche. ——W. G. Nebecker and Hugh Tarbet will take up their option on the Bullionville mine, where a large low-grade lead-silver ore has been opened up.——The district is attracting much attention, the stages are loaded with men, lodging-houses are full and charging double prices, and real estate is booming.

Pioche, Feb. 24.

Geo. Freer and Dan Harris are planning to erect a five-stamp mill on their Grand Canyon claims, near Caliente. ——Crushing will begin at the Cyrus Noble mine, at Searchlight, on March 1. Sinking for the 600 ft. level has been resumed and a raise from the third level has been completed.——F. J. Harrington and Mr. Luxon are planning development for the Big Eight property, near Searchlight.——The flow of water in the Pompeii mine has increased until it is now reported to be 160,000 gal. daily.

Lloyd, Cook & Christian have opened up an old copper claim at Bristol, 28 miles from Pioche, and have put 30 men to work. The ore is being hauled to Modena.

Joseph Dedericks of Salt Lake has taken a contract to put in the 100-ton smelter of the Good Springs Smelting & Development Co. at Good Springs. He will begin work during the present week. The company is having plans drawn for a 6½-mile electric railway to connect the mine with the San Pedro, Los Angeles and Salt Lake Railroad.——The owners of the Alcott mine, eight miles from Good Springs, are to drive a 350-foot tunnel, from the terminal of which drifts will be run.——The Black Hawk Mining Co. is erecting a mill on its property in El Dorado Canyon near Searchlight.——Superintendent J. F. Gibbs of the Nevada Gold Butte Mining Co. has selected a site and begun work on a 1,000-ft. tunnel on the Gold Butte mine near St. Thomas. This tunnel is expected to cut the six veins on the property.

Lyon County.

The Nevada Reduction Co.'s plant at Dayton is to be enlarged. An electric plant and a 100-stamp mill will be built on the old Eureka millsite. The company has bought the Winters, Sutro, Illinois, Davis, Sweetapple, Metallurgical, Excelsior and Rock Point mill and power sites, and will connect its mills with the Nevada & California Railroad.

Nye County.

The National Bank mine, near Rhyolite, is to be equipped with a 10-stamp mill to be operated by electricity.

Butler & Ramsey, operating the Congress mine, near Johnny, began work last week on the western extension of this property, known as the California mine.

The German-American Mining Co. has contracted for the erection of a blacksmith shop, engine-house, bunkhouse, boarding-house, etc., at its mine near Tonopah. Bids have been received for sinking a 600-ft. shaft. An electric hoist has been placed and sinking is to begin next week. —— A 50-h.p. engine has been ordered for the Clifford mine, at Clifford hill, near Tonopah. —— The main working shaft at the California-Tonopah mine, at Tonopah, now down 678 ft., will be sunk 125 ft. farther before crosscutting is begun. —— The newly organized Manhattan Gold Mining & Milling Co. has decided to lease three of its claims and to work the remaining claim. Six leasers are at work.

Washoe County.

(Special Correspondence.)—At Olinghouse, in White Horse mining district, the Fall River Mining Co. is sinking a double-compartment shaft on their property known as No. 1, recently purchased from Short Bros. of Reno.——The Green Hill-Nevada Corporation, owners of mining property formerly belonging to E. Olinghouse, will build a standard gauge railroad into Olinghouse canyon and will erect a 25-stamp mill on the Truckee river. The citizens of Wadsworth have agreed to grade the roadbed in consideration of the location of the mill at that place. The road and mill will be completed within 90 days. This company has taken over the plant of the Wadsworth Electric Light & Power Co., on Truckee river.——Gov. Sparks and associates have let a contract for a tunnel on their Oro claims, in Stud Horse canyon.——A rich body of ore has been struck in the lower level of the Keystone-Nevada.——The long tunnel on the Optimus has been advanced 200 feet, cutting five parallel leads. This tunnel will tap the water supply in South Olinghouse canyon.——The lower Springfield mill is running on ore from the Texas-Nevada.

Olinghouse, Feb. 26.

The Nevada Exploration Syndicate, of Reno, will drive a tunnel in White Horse district, to crosscut at a depth of 1,800 ft. the veins in that zone. Air compressors and machine drills are to be installed.

The Charlton Mining & Development Co. has been incorporated to operate mines in Nevada. The incorporators are H. Charlton, J. H. Webb, O. W. Anderson, D. L. McLean, George H. Urban, D. H. Gillis, all of Sacramento, C. T. Short of Reno, and William Hebard of Truckee. The principal place of business will be Reno.

Pres. Stephenson, of the Green Hill Mining Co., is negotiating for electric light and power machinery, after which he will proceed with plans for the construction of an 80-stamp mill on the Truckee River, at Wadsworth, and for the construction of railway from Wadsworth to Olinghouse.

White Pine County.

Engineer Biddleman is at Ely arranging the details of the Nevada Consolidated Co.'s smelting works. It is given out that four units, each of 1,000 tons capacity, will be put in.

It is expected that about 5,000 people will be in the camp at Ely as permanent residents in seven months. The Nevada company alone will give employment to 1,200 men.

NEW MEXICO.

Grant County.

The Comanche Mining & Smelting Co. will, about March 1, put two corps of surveyors at work to survey a narrow-gauge railroad from Silver City to Leopold, in the Burro mountains. This line will be used in hauling ore to the company's smelter at Silver City.——The Aurora Mining Co. has increased the working force at the Last Chance mine, where three shifts are now being employed.

Taos County.

S. M. Malette has resumed development of the Ajax mine on Pioneer creek, near Red River. —— Work has been resumed on the Edison mine, near Red River. New machinery is to be installed. The main shaft is being continued.

Grant County.

Definite announcement is made by the Comanche Mining & Smelting Co. that as soon as it has its narrow-gauge line from Pinos Altos completed from Silver City, which will be by March 1, two corps of surveyors will be put into the field to survey a narrow-gauge line from Silver City to Leopold, in the Burro mountains, and that this road will be finished by December 1 of this year. The line is to supply cheap haulage of concentrating ore from the mining properties of the company to its smelter at Silver City. The ore is blocked out and awaiting mining and shipment. The company is excavating for a new smelter at Silver City, and is grading a tramway from its concentrator to the briquetting plant of its smelter.

Six houses for employes are being built by the Aurora Mining Co., operating the Last Chance mine at Pyramid. Three shifts of men will be employed.

The Robert E. Lee Co. will purchase new machinery for its property, near Lordsburg.——The Bonny Co., which closed its mine at Lordsburg a couple of weeks ago, is buying machinery and supplies with the intention of re-opening.——The Hermosa Copper Co. has equipped an assay office and sampling plant at Hanover.——The owners of the Last Chance mine, at Lordsburg, will sink the main shaft 100 ft. farther to open new stoping ground.——The Lost Chance Mining Co. has purchased whims, hoists and other machinery for its mines at Central, and is negotiating for the purchase of the Old Texas mill at that place. The double-compartment shaft on the Lost mine is to be sunk to a depth of 500 ft. A steam hoist will be used in this work. The company is also sinking a shaft on the Bismark claim and has leased a San Jose concentrator, which will be altered and improved.

Taos County.

Gilleland & Merlin have suspended work on the Edison mine, near Red River.

OREGON.

Baker County.

Albert Geiser, lessee of the Bonanza mine, in the Greenhorn district, will start up the 35-stamp mill at Geiser this week.——Two crushers have been received at Sumpter for the Imperial mine. The remainder of the plant is expected to arrive this week.——D. W. C. Nelson, manager of the North American Mining Co., is installing an Ingersoll drill at the company's mine in the Mineral Springs district, near Baker City.——P. R. Bishop, manager of the Climax mine at Bourne, is putting in a reverberatory smelter at the mine.

Thompson & Co. are preparing to begin work on their Powder River claims, near Sparta, with a hydraulic

plant. —— The owners of the Standard mine, near Prairie City, are putting in a new reduction plant.—— A new sinking plant is being installed on the Dixie Meadows mine, near Prairie City.——The Copperopolis mine shipped its first concentrates to the Sumpter smelter last week. A 125-ton reduction plant is being put in at this mine.——The 10-stamp mill at the Gold Hill mine, near Durkee, is to be moved from its present location on Swaze creek to a point nearer the mine, abundance of water having been found in the Spring gulch vein. A sinking plant is to be installed.

Crook County.

The Gatewood Mining & Trading Co., which has bonded the Mayflower mine, near Howard, has let a contract for the erection of a five-stamp mill on the property. A cyanide plant will be put in.

Douglas County.

Arrangements are being made by the North Fairview Mining Co. for a mill near Bohemia.

Jackson County.

A. H. Gunnell states that the foundation for the 10 additional stamps at the Opp mine, near Jacksonville, is completed, making 20 stamps, which it is intended to increase to 40 by the end of the year.

Josephine County.

Frank Fowler, general manager of the Gold Pick mine, on Boland creek, eight miles from Holland, has completed the installation of a stamp mill and a concentrator.

The Southern Pacific Gold Co. took possession of the Grouse Mt. mine, four miles east of Grants Pass, last week, and preparations are now under way for the installation of a cyanide plant and electric hoist.

SOUTH DAKOTA.

Lawrence County.

The New England Homestake is a new company organized to develop 80 acres of territory lying northeast from the Caledonia mine of the Homestake Co. The main office of the company is at Hartford, Conn. A double-compartment shaft will be commenced on the vein. The main vein of the property is supposed to be the extension of the Caledonia and can be traced the full length of the New England Company's holdings.——The Elliptic Co. will resume sinking at the main shaft during the week. Some weeks ago a hole was bored in the bottom of the shaft to a depth of 460 ft. In sinking 119 ft. with the drill, 14 ft. of gouge was found overlying the quartzite, which is 25 ft. in thickness. The three-compartment shaft will be sunk to quartzite, when prospecting will be begun to find the ore-shoots which pass through the Maitland Company's property, west from the Elliptic. This is the first drill work of the kind to be done in the Maitland district, and the results will prove a stimulus to mining in the flat formation of that section.

UTAH.

Beaver County.

G. H. Waterbury, is superintending construction of a leaching plant at the properties of the Newhouse Mines & Smelters corporation, at Newhouse. The plant will have a capacity of 40 tons of ore daily. It is intended to leach the oxidized ores of the Cactus group, which show an average of 5% copper with some silver and gold.——A steam shovel is now at work on the properties of the Newhouse Mines & Smelters corporation in this county. The caving system of mining introduced in this country by Duncan MacVichie, is now in use at several Utah mines, and shows a reduction in the cost of extraction. With the steam shovel at the Cactus mines the management will add materially to the output at less cost. The enlargement of the mill at Newhouse is contemplated to a capacity of 1,500 tons daily.

Morgan County.

M. A. Dougherty, manager of the Carbonate Hill Co.'s property in Weber canyon, reports that ore-bins are being put in by the company at Strawberry Switch, three miles from Peterson.

Summit County.

It is reported that the Naildriver mine, at Park City, will resume operations.——The Daly-West mill, at Park City, was disabled last week by the breaking down of the engine operating it.

WASHINGTON.

Chelan County.

All the machinery has been installed in the new 20-stamp mill at the Washington Meteor mine, near Blewett, and as soon as the tunnel is completed the mill will be started up. It is intended to strike the orebody about 85 ft. below the old Peshastin workings. When the orebody is reached, drifting will be started in both directions. Machine drills have been installed.

Ferry County.

(Special Correspondence).—Since resuming work in the Quilp, 30 tons of ore have been shipped daily to the Sullivan Smelting Co. at Marysville, B. C. It is expected that all of the levels will soon be operated to their full capacity. Success is claimed for the concentrating tests of various lots of ore from different mines of the camp at the Mountain Lion mill. Six tons of concentrates have been shipped from the ores of the Ben Hur, Quilp and Pearl Consolidated to the Granby smelter, at Grand Forks, B. C. The concentrates from ore on the 600-ft. level of the Mountain Lion mine are being cleaned up. The tests appear to be along lines of amalgamation, concentration and cyaniding. The ore, after passing over the battery plates, goes to two Frue vanners, by which 75% to 80% of the value of the ore is said to be saved. The tailings are then cyanided for what remains in them.

Ore is being shipped in small quantities from the Mountain Lion mine. The low-grade material will be treated at the mill. If the tests have proved as successful as they have been reported, the mill will probably be remodeled and additional concentrating tables installed.

The drift on the foot-wall at the 190-ft. level of the Lone Pine is in 138 ft. and streaks of silver sulphurets are seen in the face. For delivering mine timbers and fuel, a grade has been cut alongside and a tramway built down the face of the hill to the track of the Washington & Great Northern Railway and a small steam hoist will be set at the head of the tramway. A dump of 400 tons of second-class ore is being shipped to the Granby smelter. Twenty men are employed.——The production of the Ben Hur mine has been increased to 20 tons of ore a day. It is rich in silver and gold. Some of it is visible to the eye. Four carloads of this ore were shipped to the Trail smelter at Trail, British Columbia.

The vein on the Shamrock claim, owned by Trowbridge Bros., near Dutch Jake's camp, 3½ miles west of Curlew lake and eight miles north of Republic, has a shaft down 40 ft. on the foot-wall in a five-foot vein, which assays $19 a ton in gold, copper and some silver. The full width of the vein is not known, but the cropping is very wide.——No. 2 crosscut will be started in a few days on the vein at the Oversight mine from the foot-wall side. Superintendent E. J. Delbridge is making a trial of different makes of machine drills in the various kinds of ground encountered on the Oversight.

Perrott & McCormack have made a good strike on the Stemwinder claim, which adjoins the Phil Sheridan on the north. The streak is six feet wide and assays $70 a ton, chiefly in silver, but carrying $6 a ton in gold. The last car of ore shipped from the Phil Sheridan mine, at Sheridan camp, to the Granby smelter was as follows: Net weight, 39,908 lb.; assay value, 84.40 oz. silver and 0.11 oz. gold per ton; allowed for the shipment, $1,093.62; haulage, $100; railroad freight, $41.10; treatment, $109.74. The net profit over mining, transportation and treatment was about $60 per ton. It is expected after this to ship about 30 tons a month. There remains over 200 tons of ore on the dump. P. A. McCormack is superintendent.——Monroe Harman, manager of the Ruby mine, on Mount Chopaca, Okanogan county, reports the pay-shoot on the lower tunnel level to have been exploited 20 ft. in length and 50 ft. in height. The rich pay-streak averages 20 in. in width, and a lower grade shoot which overlies it, next the hanging wall, is five feet in width, and will pay to ship as soon as railroad transportation is available. The raise on ore is 5 by 7 ft., and has separate compartments for ore-chute, a manway and a timber-slide. The water in the face of the lower tunnel is 12 in. wide and 6 in. deep, which will necessitate cutting the drainage ditch deeper. The flow has not decreased since the water was tapped. Should it increase in volume upon driving the drift ahead, it will be used to generate electric power for working the mine.

The Eureka, Alpha and Omega claims, belonging to the Gold King Mining Co., on Belcher mountain, have been bonded to the Bortle Copper-Gold Mining Co., in which D. F. Anderson, president of the Belcher Mining Co., is said to be largely interested. The Gold King claims are believed to carry the apex of the Belcher vein.

Republic, Feb. 24.

The Advance Mining Co. has nearly completed driving an 800-ft. tunnel on its property eight miles south of Daisy, in Stevens county.

King County.

The contract for a smelter at some place between Seattle and Tacoma by the Copper-Lead Smelting Co., in which J. Furth, J. H. McGraw and J. A. Moore, of Seattle, are interested, was let on Feb. 12 to the Union Iron Works, of San Francisco. H. Haas, consulting metallurgical engineer for the Union Iron Works, who has been in Seattle for some time, concluded the negotiations. He says that actual construction of the plant will be commenced in June, and the total cost will be more than $1,000,000. The smelter will have a daily capacity of 1,000 tons of copper ore and 500 tons of lead ore, and will be the largest plant west of Anaconda. The plant will consist of a copper-converting plant, a 50-ton copper refinery, a 50-ton lead refining works, a 50-ton gold and silver refining works, a 500-ton stamping works, a 250-ton roasting plant for the treatment of flue dust, and a flue chamber 1,000 ft. long, with a cross-sectional area of 1,000 sq. ft., terminating in a stack 20 ft. diameter by 250 ft. high, in addition to the smelting capacity for copper and lead. The blast-furnaces will be mechanically charged. The latter will be completed by January, 1907, and the copper refinery during 1907.

Lincoln County.

A. O. Hellen, of the Hellen Mining Syndicate, reports that the 40-ton crusher and concentrating plant is now on the ground on the Swank, near Cle Elum.——The Washington Quicksilver Co. has arranged to build a wagon road to its property near Cle Elum. When this is completed a 50-ton reduction plant will be put in.

Okanogan County.

A. M. Wehe, of the Golden Gate mine at Wehesville, is running a tunnel on the ledge.——The Multnomah Mining Co. has cut a third ledge in running its tunnel a distance of 765 ft. The tunnel will be continued to the Multnomah ledge.

Stevens County.

John Keough has contracted to purchase the Anaconda and Copper King properties on Fish creek, northeast of Northport. The contract requires that not less than eight men be put to work immediately.——The Silver Queen Mining Co., of Spokane, lessees of the Silver Queen group, two miles south of Kettle Falls, is sinking a shaft.——The owners of the Daisy mine, at Daisy, 25 miles south of Kettle Falls, are planning to put in a concentrator.——The Jupiter Lead Co. is running a tunnel at the Jupiter lead mine, seven miles east of Northport, to strike the vein below the old workings for draining and more advantageous working. Sinking from the upper workings is also in progress.——Operations have been resumed at the Sunset mine, near Northport, after a shut-down of two months.——The owners of the Hecla mine, near Northport, will put in a concentrator and resume operations on a larger scale.——The owners of the Zodiac mine, on Sheep creek, west of Northport, have their crosscut tunnel in 600 ft. and are expecting to reach the orebody soon.——Abram Bros. began sinking last week on a vein in their property near Northport.——The owners of the Pearl Consolidated are drifting on the 200 level of their mine near Northport.

The Oversight Mining & Milling Co., of Seattle, has installed a three-drill compressor on its property on Belcher mountain, near Northport. A tunnel is now being run on the foot-wall of the main ledge and another on a ledge recently found.

Whatcom County.

C. E. Sheppard, representing the creditors of the Nooksack Mining Co., of Nooksack, bought in practically all of the company's property, for $9,598, at sheriff's sale a few days ago.

FOREIGN.

CANADA.

BRITISH COLUMBIA.

Official figures of the British Columbia Copper Co.'s Greenwood smelter for the year 1905 show the amount of ore treated to be 210,830 tons, the amount of custom ore received being 16,357 tons, the balance coming from the company's Mother Lode mine at Deadwood. The Mother Lode mine shipped during the year 174,567 tons, the difference between tonnage smelted and tonnage of ore received being made up of material other than ore, such as flue dust from storage, and in the reduction of ore stock.

The Dominion smelter at Boundary Falls is treating about 700 tons of ore daily.——The Granby Co. have taken a working bond on the Pathfinder group on the north fork of Kettle river.——A drift on the 350-ft. level of the Brooklyn mine cut an orebody which had been lost in the upper workings.——The Granby Consolidated is five years old. The first ore shipped from the Granby mines was in July, 1900, and since that time 2,258,458 tons of ore have been shipped and treated at its smelter, as follows:

	Tons.
1900 (six months only)	64,538
1901	231,762
1902	309,858
1903	393,718
1904	549,703
1905	653,889
1906 (January)	74,995
Total	2,278,458

Its smelting capacity is now 2,700 tons per day. It has one of the best equipped and most economical copper-smelting plants in the world. In 1905 a recovery of 26 lb. of copper per ton of rock was secured.

ONTARIO.

A rich find of gold in quartz is reported from the Laurentian mine, near Dinorwic. Prospecting is being done with a diamond drill.

MEXICO.

Coahuila.

The Mazapil Copper Co., of Saltillo, is planning a long tunnel from Concepcion del Oro, in Zacatecas, to the Aranzuzu copper mines.

Durango.

It is reported that the American Smelting & Refining Co.'s smelter at Velardena will not be ready for blowing in before July. The concentrating mills and plant have been increased in capacity. Trams and ore-carriers have been installed and the power plant improved. The smelter will have a daily capacity of 2,000 tons. The Chihuahua smelter, work on which has been commenced, will be ready to blow in within a year. It will start with a capacity of 500 tons of ore, to be increased in accordance with the demand.

Los Marches Mining Co. has completed the installation of a concentrator at Inde. The furnaces at the new smelter will be blown in during March.

Mexico.

The Borda Antigua Mining Co., located at Tlapujahua, is running its mill and concentrating plant. The estimated tonnage of the upper Antigua workings is about 30,000, with a value of $5 to $10 gold per ton. The manager of the property is Jose Luis Requena, president of the Dos Estrellas Company.

Oaxaca.

It is announced that the new Oaxaca smelter, at Magdalena will be ready to blow in by April 1. The plant will have an initial capacity of 75 tons per day.

Sinaloa.

The Tajo mines, near Rosario, have been shut down to permit reconstruction of the mill. A cyanide plant will be substituted for the amalgamating plant. It is reported that the plant will have a capacity of 250 tons per day.

The Compania Minera Guadalupe de los Reyes will instal a 5,000-h. p. hydro-electric plant to furnish power for its mines near Cosala. R. McF. Doble of San Francisco, Cal., is drawing up the plans. —— The electrical machinery for the mines of the Compania Minera de Panuco, near Concordia, has arrived.

Sonora.

A small smelting plant is being erected by the Santa Ysabel Mining Co., 25 miles south of Nogales, Arizona.

The Giroux Consolidated Mining Co., of Capote, is receiving machinery for a reduction plant, including a 60-ton smelting furnace and a 10-ton stamp-mill. Both amalgamation and cyanide processes will be used.

NOVA SCOTIA.

Queens County.

The Brookfield mine—the deepest, and in the past one of the most productive mines of the province—has been closed, the reported reason being unwarranted interference of an organization known as the Lord's Day Alliance, which objected to work being prosecuted on the Sabbath.

Personal.

S. F. PARRISH is at La Jolla, California.

W. M. CLARK, of Guanajuato, is visiting Denver.

F. L. BOSQUI has returned from Goldfield, Nevada.

OTTO SUSSMANN, of Salt Lake City, is in New York.

C. E. BORTLE, of Republic, Washington, is in the East.

M. D. SCHRIBNER, of Tombstone, Ariz., is at the Palace.

C. H. MUNRO, of Portland, is about to proceed to Alaska.

F. W. BRADLEY and MARK L. REQUA are at Ely, Nevada.

R. GILMAN BROWN has returned from Ymir, British Columbia.

THOS. H. LEGGETT has returned from Mexico to San Francisco.

MARK B. KERR has returned to Tonopah from San Francisco.

J. HERBERT CURLE is in Florida. He will proceed shortly to Japan.

A. A. TALMAGE, of the Blaisdell Co. of Los Angeles, is in Mexico City.

THOS. B. STEARNS, of Denver, is taking a short holiday at New Orleans.

FREDERICK H. HATCH is returning from the Rand, to reside at London.

CHARLES JANIN is on his way to London, to take a well-earned holiday.

D'ARCY WEATHERBE has arrived in San Francisco from British Columbia.

FREDERICK LYON is in San Francisco from Kennett, Cal., at the St. Francis.

NEWTON B. KNOX has joined the staff of Bewick, Moreing & Co., London.

J. OBALSKI has been appointed director of mines for the Province of Quebec.

B. F. EDWARDS, of the West End Mining Co. of Tonopah, is in San Francisco.

MALCOLM L. MACDONALD, of Tonopah, came to San Francisco for a few days.

CHARLES A. MOLSON is examining the Nevada Consolidated copper mines at Ely.

WILLIAM N. CUMMINGS, of Guanajuato, is examining mines at Silver Peak, Nevada.

W. P. RUTHERFORD has returned to London from an examination of mines in Japan.

D. A. FREEMAN, of Los Angeles, who is mining in Mexico, is visiting San Francisco.

L. H. JANSEN, of Kansas City, visited San Francisco on his way to Western Sonora, Mexico.

P. A. MCCORMACK is superintendent of the Phil Sheridan mine, at Sheridan Camp, Washington.

J. TROWBRIDGE BAILEY, of New York, is investigating the dredging industry at Oroville, California.

JOHN ROSS, JR., of Sutter Creek, and E. L. DAVIS, of Telluride, Colorado, are visiting San Francisco.

ALBERT LADD COLBY has opened an office as iron and steel metallurgist at 477 Central Park West, New York.

STEPHEN C. THOMAS has returned to Sutter Creek after having been in charge of the Caribou mine in Nova Scotia.

ROBERT C. GEMMELL has been appointed general superintendent of the Utah Copper Co.'s mines, at Bingham.

C. B. LAKENAN has gone to Philadelphia, whence he will proceed to Panama to report on some placer mining properties.

F. E. FIELDING has recently opened an office at 201 Henne Bdg., Los Angeles, Cal., which is run in conjunction with his office at Reno, Nevada.

EMERSON GEE returned to Los Angeles for a few days after a stay of five months on the west coast of Mexico. He will be at Culiacan, in Sinaloa, for the next three months.

R. S. RAINSFORD, of Salt Lake City, has left the employ of the Guggenheim Exploration Co. to become field engineer for the American Smelting & Refining Company.

THEODORE DWIGHT has resigned as assistant secretary of the American Institute of Mining Engineers and has become president of the Mineral Development Company, owning mines in Mexico.

THOMAS L. WILKINSON has resigned the position of assistant general manager and engineer of the South West Smelting & Refining Co., of Jarilla Junction, New Mexico, and has returned to Denver to resume his individual practice.

C. G. WARNFORD LOCK has just returned to Singapore from a three months' tour of inspection and exploration in Kenaman, one of the independent native States of the Malay Peninsula, and has since been engaged in reporting on tin mines in the neighborhood of Raub.

CHARLETON, DICKINSON & CO., mining consulting engineers, of 353 Mansion House Chambers, London, announce that they have arranged with Mr. Lock to act as their representative. Mr. Lock has opened an office in Singapore, and Messrs. Charleton, Dickinson & Co. have arranged to represent Mr. Lock in London.

METALS.

SILVER.—Per oz., Troy: New York, (by wire), bar silver, 66⅜c. per fine ounce; San Francisco, 66¼c.; London, 30½d. (standard ounce, 925 fine); Mexican dollars, 52@54c., San Francisco; 51½c., New York.

COPPER.—New York (by wire, average for week ending March 1), Lake, $18.37@18.50; Electrolytic, 18.12@18.37c.; Casting, 17.75@18c. per pound. Mill copper plates, $21; bars, 21@24c. London: £78 spot per ton.

LEAD.—New York (by wire, average for week ending March 1), $5.35 per 100 lb; San Francisco, pig, 5.70@6.60c. per lb.; pipe 8@8½c.; sheet, 9@9½c.; London: £16 2s. 6d. ℔ long ton.

SPELTER.—New York (by wire, average for week ending March 1), $6.05@6.10 ℔ 100 lb.; London, £25 17s. 6d. ℔ ton; San Francisco, ton lots, 7c.; 100-lb lots, 7¼c.

TIN.—New York, pig, $36.15@36.35; bar tin, ℔ lb., 42½c.; pig, 39c. London, £165 10s.

PLATINUM.—San Francisco, crude, $18.50 ℔ oz.; New York, ingot, nominal, $20@25 ℔ Troy oz. Platinum ware, 75@$1.00 ℔ gram.

QUICKSILVER.—New York, $40.00@$41.50, large lots; London, £7 7s 6d.; San Francisco, local, $38.00@39.00 ℔ flask of 75 lbs.

NICKEL.—New York, 48@60c ℔ lb.; ton lots, 40@47c.

ZINC.—Metallic, chemically pure, ℔ lb., 50c.; dust, ℔ lb., 10c.; sulphate, ℔ lb., 4c.

BABBITT METAL.—San Francisco, No. 1, 10½c.; No. 2, 8c.; No. 3, 7½c.; extra, 17½c.; genuine, 32½c.; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 23.50c; San Francisco, Plumbers', 100-lb. lots 19.75c.

ALUMINUM.—No. 1, 99%, small lots, 35@38c. ℔ lb.; 100 lbs., 35c.; 1000 lbs., 34c.; ton lots and over, 33c., Pittsburg. No. 2, 90%, small lots, 34c.; ton lots and over, 31c, Pittsburg.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $18.35; gray forge, $17.85; San Francisco, bar, 3½c. ℔ lb., 3¾c. in small quantities.

STEEL.—Bessemer billets, Pittsburg, $27.00 open hearth billets, $28.00; San Francisco, bar, 7c to 13c ℔ lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 8½c.; less than 500 lb., per lb., 8½c.; in 25-lb. tin pails, ½c. ℔ lb. above keg price; in 1 and 5-lb. tin cans, 100 lb. per case, ½c. per lb. above keg price. Dry Lead.—In bbl., 1 ton and over, 8c.; do. in kegs, 8¼c.

LIME.—Santa Cruz, $1.35 country, $1.25 city ℔ bbl.

CEMENT.—Imported, $3.00@4.00 ℔ bbl.; California, carload lots, $1.80 f. o. b. at works; small lots, $2.10 ℔ bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

LUMBER.—(Retail): Pine, ordinary sizes, $24.00@25.00; extra sizes higher; redwood, $28.00@30.00; lath, 4 feet, $4.50@5.00; pickets, $21.00; shingles, $2.50 for No. 1, and $2.25 for No. 2; shakes, $13.50 for split and $15.00 for sawed; rustic, $28.00@35.00.

NAILS.—This week the basic prices are: Wire, $1.85; Cut, $1.75. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d, Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4d and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

GENERAL SUPPLIES.

ANTIMONY.—New York, per quality, 16c@17c; San Francisco, 1000-lb. lots, 16c; 300@500-lbs. 12c, 100-lb. lbs. 12c; 100-lbs lots, 13c.

BONE ASH.—Extra No. 1, 6c ℔ lb; No. 1, 5c½.

BORAX.—Concentrated, 9½c ℔ lb; powdered, 10c; fused, 25c; crystal, refined, 8c.

CANDLES.—Standard Oil Co.—Electric light, 16 oz., 11c; 14 oz., 9¾c; 12 oz., 8½c; 14 oz., 7¾c; Hotel, 12 oz., 9c; Granite (mining), 16 oz., 11½@11½c; 14 oz., 10@10½c; 12 oz., 9½@9½c; 10 oz., 8½c; Paraffines, White, 1s, 2s, 4s, 6s, 10½c; 12s, 11c; colored, 1c higher; Radiant Paraffines, 4s, 6s, 14 oz., 9½@9¾c; 10 oz., 7¾c.

CAPS.—3x, $5.50@6 per 1000; 4x, $6.50@7; 5x, $8@8.50; Lion, $9@9.50, in lots not less than 1000.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 23@24c ℔ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 3@3½c ℔ lb.; caustic soda, in drums, 3@3¼c ℔ lb.; Cal. s. soda, bbls., $1.10@1.20 ℔ 100 lbs.; sks., 90c@$1.00; chlorate of potash, 12@13c; nitrate of potash, 6¾@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2½@2½c; flour sulphur, French, 2¾@—c; alum, $2.00@2.25; California refined, 1¾@2c; sulphide of iron, 8c ℔ lb.; copper sulphate, 6½@7c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66° B, 1¾@2c ℔ lb.; nitric acid, carboys, 8c ℔ lb.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1**, 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2**, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

COAL.—San Francisco, coast, yard prices to dealers: Wellington, $7.50; Seattle, $6.50; Coos Bay, $5.50; Cargo lot, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $14.00; Cannel, $8.50; Rock Springs, $8.50, long ton; Colorado Anthracite, $14.00. Coke, $11.50 per ton in bulk, $13.00 in sacks; Sunnyside, $8.50, long ton.

Commercial Paragraphs.

OFFICE of the Empire Consolidated Mining Co. of Searchlight, Nev., is now located at 201 Henne Bldg., Los Angeles, Cal., late No. 402 Douglas Block.

THE Union Gas Engine Co. shipped a 30-h. p. 'Union' double-cylinder stationary engine to the Ruth Pierce Mining Co., Hornitos, California. The engine is fitted to run on distillate and crude oil.

THE A. Lietz Co., manufacturers of high-grade surveying, engineering, mining and nautical instruments, announce the removal of the factory, main office and show rooms to their new four-story brick building, 632 and 634 Commercial street, San Francisco. They have a branch salesroom at 207 Montgomery street.

THE Tallapoosa Gold Mining Co., Yates, Ala., have bought from the Allis-Chalmers Co., Milwaukee, machinery for a five-stamp cyanide mill with steam power, for installation at Alexander City, Ala. The Alaska-Treadwell Gold Mining Co., Treadwell, Alaska, recenlty ordered a 20x48 double-drum, direct-acting hoisting engine from this firm.

THE Lima Locomotive & Machine Co. of Lima, Ohio, report that the Duluth, Virginia & Rainy Lake Railroad Co., Duluth, Minn., has placed an order for one 65-ton Shay locomotive; L. B. Walling, Victoria, Fla., has placed an order for one 15-ton Shay locomotive; Sumpter Lumber Co., Sumpter, Ala., has placed an order for one 37-ton Shay locomotive.

THE General Engineering Co. has been incorporated under the laws of Utah, with offices in the Dooly Block, Salt Lake City, Utah. The purpose of the company is to do a general mining, metallurgical, civil and mechanical engineering business. J. M. Callow is president, J. W. Neill vice-president, F. E. Johnson secretary and treasurer, and in addition to whom are G. M. Bacon and F. P. Callow, members of the staff. Milling, concentrating and other metallurgical tests will be made on ores in 100-lb. lots.

THE new ore-testing plant of the Colorado Iron Works Co., erected at its works in Denver, is kept constantly busy on lots of ore that come from many parts of the world. The equipment includes stamps, crushers, rolls, impact screens, concentrating tables, amalgamating plates, cyanide leaching vats, classifiers for separating sand from slime, and a well-equipped chemical laboratory. The company recently received and are filling the following orders: Four sets of 48 by 24-in. belted rolls and two sets of 48 by 24-in. geared rolls for the American Smelters Securities Co.; a 42 by 120-in. coppermatting furnace, for the Utah Smelting Co., Ogden, Utah; a 42 by 150-in. copper matting furnace, with accessory equipment, for the Great Western Gold Co., Shasta county, Cal.; one matte tramway, with settling bowls, special electric hoisters, sixteen 8-ft. self-dumping slag trucks, and five 35-ft. screw-dump slag-trucks for the Compania Minera Fundidora y Apinadora, Monterey, Mexico.

Trade Treatises.

'Petroleum Lubricating Oils' is the title of a neat little brochure issued by the A. W. Harris Oil Co. of Providence, R. I. It describes, with illustrations, the various grades of lubricator made for numerous purposes by this firm.

The F. M. Davis Iron Works Co., of Denver, has issued Catalogue No. 37, Ore Milling Machinery; No. 38, Smelter Machinery, and No. 41, Hoisting Machinery; No. 43, The Ferraris Ball Mill. These will be sent on application to the company.

'Concentration' is the title of the latest trade publication of the Joshua Hendy Machine Works, catalogue No. 17. It is a work of art typographically, and contains much valuable information on the art of concentration, and is devoted particularly to a description of the Pinder concentrator and its operation.

Books Received.

'Proceedings of the American Forest Congress,' by the American Forestry Association, is a volume of 474 pages, which deals with forestry conditions in the United States, and with forestry is related to irrigation, the lumber industry, grazing, the railroads and mining, and contains much of value to all interested in the lands of the public domain.

Obituary.

CHAS. SMITH, who for many years has been a millman at Mother Lode mines, died at Pine Grove, Amador county, on February 23.

EDITORIAL.

OUR contemporary, the *San Francisco Chronicle*, publishes a budget of mining news each Monday. This week there is a paragraph which is worth repetition for its cynical humor—whether intentional or not, we do not venture to say. It is stated that control of a certain copper mine in California has passed "to the American smelting trust, one of the subsidiary organizations of Amalgamated Copper and Standard Oil." The last sentence is one of those statements which are labeled "important, if true." We doubt, however, whether the Guggenheims are subsidiary to anyone at the present time, they give no signs of subsidence, either local or regional; but our contemporary evidently expresses a fear, which has grown of late, and which we share, that the big industrial combinations appear bent on a co-operation which cannot but be hurtful to the community, more especially those engaged in mining and smelting, by the creation of a huge monopoly prejudicial to anything like legitimate competition.

COBALT, in Ontario, is already the scene of the rush that was expected this spring, and that celebrated silver-nickel-cobalt camp is sure to attract further attention among mining men. The article by Mr. D'Arcy Weatherbe, of our staff, is timely and those who read it will obtain information likely to prove useful, especially if they contemplate contributing their presence to the local excitement. Our Toronto correspondent also gives later news from this part of the continent and describes the efforts recently made to improve mining regulations in the Province of Ontario. It is apparent that the legislature has awakened to the growing importance of the industry and means to give fair treatment to those who, whether as prospectors, engineers or capitalists, are likely to take part in the development of Ontario's undoubtedly extensive mineral resources. The arrangement to throw open the timber grants is a step in this direction; those who are well informed expect it to be the precursor of further finds of valuable ore in Temiscaming.

WE have been favored with an authoritative account of the great cantilever bridge across the Victoria Falls, of the Zambesi. Our readers will find it interesting. The height of Niagara is 158 feet, while that of the Victoria Falls is 420 feet; the width of Niagara is about half a mile, while that of Victoria is twice as much, so that this manifestation of natural energy must be greatly impressive. The bridge is important as affording a crossing to the railroad, which will stimulate the development of northern Rhodesia and central Africa in general.

THE market for South African shares, known at London as 'Kaffirs,' has suffered a collapse, such as would have been considered quite impossible a few years ago. Rand Mines, a consolidation of interests in a number of the richest mines on the Rand, has been quoted at £5⅛ this week, as compared to £13½ at the time the Boer war ended. This represents a strong reversal of financial sentiment, for Rand Mines has long been considered the "consols of South Africa," an investment that could not be moved though the heavens fell. The drop in Kaffirs means a loss of millions sterling, because however much of the present depression may be due to a feeling of panic over possible political developments, which may not in the end prove as hurtful as supposed at the moment, it is certain that confidence in the best of the South African mining shares as a non-speculative investment has been shattered beyond any mending. This will tend to lessen English participation in mining, because it has undermined the confidence of investors; but in the end, and before long, it will have the effect of diverting British money to other mineral regions.

FROM London we get our usual news-letter, and this week it is particularly interesting. To our Cornish friends it will be like a message from home to read of the mining revival in the 'old county,' this development being due to new discoveries of tin ore at Wheal Grenville mine, as well as at the 'old reliables,' Dolcoath, Carn Brea and Tincroft. The mining terms used by our correspondent, himself deeply versed in such matters, will be familiar to Cornishmen, while to others they will serve as a reminder of methods which long antedated the discovery of gold either in California or Australia. The 'cost book' system is based on the idea of partners who divide profits and share losses each month; the shareholders are called 'adventurers' in the sense in which Raleigh, Drake and Hawkins were adventurers, that is, they ventured forth into the unknown seeking either territory, gold or sport. The 'call' is an assessment, the 'bal' is the mine, the 'sett' is the ground under lease, 'black tin' is tin oxide (cassiterite) in distinction to the metal itself. The 'streamers' are the men who work the stream tin, the alluvial deposits, partly natural, partly the tailing from the mills or 'dressing floors.' When it comes to the 'Lord's dues' our readers may suppose that the tithing system or a contribution to the church is indicated. No, it is the rent payable to the landlord or owner of the claims, that is, the territory exploited by the mining company. Our Cornish friends still measure in fathoms, and not in feet as we do, indicating their larger ideas of exploratory work; for it is true in mining more than in any other field of activity, that those who seek are those that find.

THE article drawing attention to Job as the first writer on ore deposits will cause a flutter among our friends at Washington and New York, who had good reason, until now, to consider themselves the real thing in that branch of knowledge. But they grow haughty sometimes and deprecate the investigations of the less learned, therefore this new reading of the prophet of the land of Uz will be appreciated by our readers. It is obvious that the writer of the article is deeply learned in things holy and unholy, but he has overlooked a more recent communication from regions usually known only by hearsay. In that strange epistle to the Nevadans known as 'The Geology of Jell,' by a prophet who is not without honor in his own University, there is disclosed the innermost workings of Plutonic activity. We shall quote from it next week. The traveler from the deep, who knows a thing or two, says, among other things, that "the various kinds of igneous rocks are produced under the direction of the Jevil-in-Chief, very much as charges are mixed for a furnace. When the Jevil-in-Chief orders andesite, he issues instructions for the proper proportional parts of these ingredients, and the subordinate jevils run them together and over into a spout which connects with the volcanic conduit. Into this and on the principle of the injector, are run under enormous pressure steam and other mineralizers and the whole mixture, boiling and seething, forces its way through the zone of flowage and so to the upper world." But we must not anticipate. The copyright for this communication was printed on asbestos and bears evident marks of genuineness. Our readers will, we believe, feel proud when we put them in possession of both the first and the last word on a subject of such transcendent economic importance.

Smelters and Their Fume.

It is fairly certain now that the Guggenheim interests, otherwise known as the American Smelters Securities Corporation, will build a large copper smelter in the vicinity of San Francisco. The size of the plant is yet to be determined, but it is not likely to include a refinery; that last stage of the metallurgical process will be completed at Tacoma, where a refinery exists already. The northeastern end of the Bay of San Francisco has been the favorite site for smelters; the Selby works, the Copper King plant and the new Mountain Copper smelter having been erected along that shore of the Sacramento estuary. This locality is near the trans-continental track of the Southern Pacific Railway, of the Oregon and northern California branch line and, latterly, of the Santa Fe railroad. But the farmers have a habit of getting busy with damage suits in that part of the country and poor looking horses are found to increase in value when they eat smelter fume, so that such practices have become irksome to the smelter managers and this important industry now fights shy of Port Costa, Benicia or Martinez. It is understood that the new plant, a large copper smelter that will supplement the Selby lead reduction works, will be erected on the southwest shore of the Bay, at Point San Bruno, in San Mateo county, about six miles south of the city of San Francisco. The prevailing winds, for nine months in the year, are the westerly trades, so that the smelter smoke will drift across the water, here four to five miles wide, and in its crossing be rendered harmless to even the most susceptible cow. Speaking of smelter fume, we note

that the United States Circuit Court of Appeals has reversed the decision whereby an injunction was granted against the Mountain Copper Company, at Keswick, in Shasta county, California, on the ground that "the acids generated by the smelting works were injuring Government property." Two of the judges decided that it was contrary to public good to stop the operations of a large industrial establishment in the interest of the owner of 4,000 acres of granitic territory, worthless for agriculture, and already deforested. Judge Hawley, the minority, pronounced the dictum that "the innocent are not to suffer either in their property or comfort for the promotion of another's interest or profit." And this idea is undoubtedly at the base of all blackmailing suits brought against the smelters. They are always willing to buy land or compensate the owners of it when such land comes within the radius of their smoke nuisance, but they are not allowed to treat such cases equitably; on the contrary, they are put in the position of enemies of the public good. We regard the smelters as representing a beneficent industry, the wellbeing of which is essential to profitable mining; and in taking this view of them we disregard the financial schemes involved in their organization and the speculative share market which some of them afford. As the promotions of clever financiers they do not interest us, they are able to take care of themselves, but as an integral part of the vast operations by which the mineral resources of the country are exploited, it does appear to us that they should not be hunted from pillar to post by blackmailing pseudo-farmers who trade on the notion that a ranchman is a benefactor and a smelterman a criminal. The greatest good of the greater number is the aim of intelligent government; a right of way for a railroad can be obtained through another's land by proper legal proceedings, a city can extend a street by condemnation suits and, in general, the individual who obstructs a development conducive to the public benefit is politely told to be reasonable, and, eventually, compelled to take fair compensation. Fair compensation the smelters have always been willing to offer, unending blackmail they have fought. It would be to the injury of our community and of the State of California if the idea should prevail that a people whose existence was founded on mining has made up its mind to treat all smelting works as a public menace.

Wanted—A Wake.

We might have called for a funeral, only that would be too depressing, while an Irish wake with its mournful features enlivened by a bibulous accompaniment and the recitation of the deeds of the dear departed, just fills the needs of the occasion. Besides, at a wake the corpse has been known in rare instances to come to life again. We refer to the proximate end of the Royal School of Mines, London.

We have received a copy of the final report of the Department Committee appointed to consider what changes were necessary to give greater usefulness to the Royal College of Science, "including the Royal School of Mines." By the same mail comes a copy of our contemporary *The Mining Journal* giving an account of the recent School of Mines dinner at which a presentation was made to Professor John W. Judd, on his retirement as dean of the School. On that occasion the alumni and their friends united to do honor to one who, as teacher and as author, stands among the great men of geologic science; his retirement coincides with the approach of a new era and it is no wonder that the speakers at the dinner all expressed, in varying phrases, the hope that the Royal School of Mines may not be absorbed by any other institution. Having read the Committee's report and knowing something of the cross-currents that stir the lethargy of British interest in mining education, we have a profound and heartfelt regret that the School identified for over half a century with so much that was brilliant, honorable and useful should finally fall into the maw of a nondescript agglomeration.

The committee recommends that there be established an "institution or group of associated colleges, of science and technology," "to include the work of the Royal College of Science, the Royal School of Mines, the Central Technical College and departments to be established on the additional site at South Kensington." Thereupon arises the question, so the committee says, "What should be the relation of the new institution to the University of London?" but this matter is held in abeyance, with ominous signs of being decided in the affirmative; that is, the new institution is likely to be incorporated in the University of London.

And so one of the great schools of mines will be finally destroyed. It is all well enough to speak of improved facilities, larger schemes and the retention of the degree; but when you change the lock and barrel of a gun, even if the stock remains, you have lost the old weapon. We have no patience—and do not apologize for it—with the stupid neglect and final emasculation of the only mining school in the British Empire that has any traditions enabling it to rank with other places of its kind in Europe or America. The Royal School of Mines was started to train geologists and mining engineers fifty-five years ago, and it has numbered among its graduates men of rare usefulness. In 1879 it was moved from Jermyn street to South Kensington, and became part of an institution for training science teachers, the change proving highly injurious to the individuality and identity of the original establishment. Nevertheless, there was a good deal of college spirit at South Kensington, and an excellent training was obtained from a corps of teachers, many of whom had worldwide celebrity, and were not only effective lecturers, but great men. Now, not content with the blunder of grafting the old school onto a nondescript teachers' seminary, it is to be annexed to an industrial academy and finally to be absorbed by a mushroom university. It is stupid to make comparisons with Columbia University and its School of Mines; that university is a century older than its mining school; and the latter gains by the association. The scheme outlined at London is more like a proposal to join the Columbia School of Mines to New York University and to agglomerate both with a Brooklyn business college.

Sentiment apart—and sentiment is a power for good even in these money-grubbing days—we hold that the usefulness of the School is destined to be crippled by the new departure, because the special training will be swamped amid the diverse curriculum of the proposed institution; it cannot afford the spirit of a school intended to train professional men, and it will not attract the teachers that a smaller better-defined technical college does. As between the theoretical, scientific instruction of the big universities and the practical training of a provincial school of mines, there is need for an establishment combining men possessed of the highest ability to exposit science, with the instruction that can be given only by the men who have actually done the work of the engineer, and experienced the difficulties that the mining student is destined to face. That combination is attainable at a concrete school of mines and not within the wide-spread boundaries of a technologicum that can never appeal with any force to the support of the profession.

This British effort to create a grandiose Charlottenburg is as far as the poles asunder from the ideal of a small school of mines, receiving graduate students from other universities and colleges where a preliminary scientific instruction has been obtained, reserving the special training for the School of Mines itself, with a separate identity, noble traditions, a few first-rate teachers, supplemented by occasional courses of lectures from experienced engineers, the whole cemented and quickened by professional solidarity and enthusiastic support. The day has come, assuredly, when we ought to realize that mere bigness does not count for much in an educational center; unrestrained annexation produces only the jelly-like shapelessness of the lower forms of animal life and complex organization wearies itself out with red tape and departmental delays. It is a pitiable thing that an Empire which controls two-thirds of the gold production of the world and a financial center like London, holding the financial reins of a mining industry, the output of which is measured by the revenue of one or two continents, should be able to do no better than this—to smother the school of Ramsay and Tyndall, of Percy and Smyth, of Huxley and Judd, between the folds of an inflated kindergarten. If it be carried out to the bitter end, we look for an increase in the number of men, already not inconsiderable, who will enter at the mining schools of the United States.

By the Way.

In *Popular Science Monthly*, Mr. A. C. Lane, State Geologist of Michigan, makes some sound observations. He says:

The youth of a people is in reality like that of a man, full of hope, extravagant, feeling boundless resources and inclined recklessly to squander them in attaining the objects of desire. If it is wisely guided, age may bring riches which are not merely in prospect, but in possession, which are the fruits of useful industry. Unwisely guided, age may bring the exhaustion of the resources thought to be boundless, with nothing worth while to show for them; and as the individual man may be found bankrupt in purse and pride, so the nation or community may suddenly find its supposedly inexhaustible supplies exhausted, the fabulous fertility of its fields failing, its hills once clad in forests naked and seamed and gashed by gullies until they remind one of the beggar's clothes whose spendthrift habits have dragged him down to like depths of destitution.

Mill says that "looking on the world as not only the home of man, but as subservient in all its phenomena to the welfare of the human race, we may consider the development of any region to mean such treatment of its natural resources as will enable the land to continue to support an increasing number of inhabitants," and ventures the suggestion that "fortune hunting is inimical to development in its true sense. A fortune acquired through production or speculation can usually be made by only a few individuals and almost always entails the exhaustion of natural resources or the lowering of wages; a prosperous livelihood, on the other hand, can often be secured to a multitude without permanent impoverishment of the land." The former statement we may consider a fair definition of development of a country. The latter is one of those general statements which are hard to disprove, being both vague and qualified. But it suggests that there may be such a thing as improper development. Much talk and writing seem based on the theory that development is always and only good—is a good in itself. This we may fairly question.

In the first place, note that the development of national resources does not in all cases imply consumption. It is true that one can not eat one's cake and have it too, but it is also true that one can use a house, see a picture, and gaze at a statue, and they be none the worse for it. Italy and Greece are vastly wealthier to-day than they would have been had the marbles of their statues remained in the quarries of Pentelicos, Paros or Carrara.

As a second class we have the resources of which there is a continuous and transitory supply, in contrast to those of which there is a stock, in the using of which we are drawing on an original supply or the accumulation of generations. The farmer's windmill in using wind power is using a resource of the former class, while the use of coal is drawing on a reserve. Farm products so far as they are due to air, water, sunshine and hard work, the minting of golden sunshine into golden grain, are a development of resources continuously supplied, but there is also a little ash or mineral matter which, if not replaced by manure or fertilizer, is a draft upon the capital of the commonwealth. Most important perhaps of these resources is water power, which is indeed largely used, but of which there are millions of horse power yet unused. Any permanent substantial dams which may help us to utilize this will be a permanent gain to the resources of the State.

Third, are the resources which are wasting away in the use. As we gaze on a piece of soft coal across the cleavage, we shall see dozens of alternating bright and dull bands in an inch. Each of these may represent an annual or semi-annual change of climate, and a ton of coal may represent 30 tons of wood. Thus in using coal we are dissipating in a few years the accumulations of generations heaped up millions of years ago. Now of these reserve accumulations, and I can not emphasize the fact too strongly, there is never an inexhaustible supply. People a scant half century ago used to talk of the inexhaustible supplies of pine in the Saginaw. There is now hardly a stick standing. Men prate of inexhaustible mines. There are no inexhaustible mines. The bottom of perhaps the greatest mine in the world, the Calumet & Hecla, on its conglomerate is much too visible. The Spindletop bubble has already burst, and its wealth has practically vanished, wasting what should have been the industry of a generation in a scant decade. The towns that had natural gas no longer burn it in flambeaus that burn millions of cubic feet a day, but charge 20c a thousand for it. Of course sometimes the supplies are in a way practically inexhaustible. The salt of Michigan, if the present rate of production of two billion pounds a year is not too greatly exceeded, might probably last some two million years. Yet the consumption will increase—we know not how much, and a much less time and amount would threaten the collapse of Detroit beneath Lake Erie. They talked only a few decades ago of inexhaustible supplies of iron ore; at the present rate of consumption of some 23,000,000 tons a year, there is probably enough for 80 years' consumption. Still, that is not a very long time in the lifetime of a nation.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and to give information dealing with the practice of mining, milling and smelting.

IN electricity a watt is one ampere flowing at a pressure of one volt.

ALL KINDS of nitro-glycerine powders may properly be called dynamite.

ARAGONITE is a natural precipitate of calcium carbonate from springs.

IN mill screens No. 7 slotted screen is about equivalent to that known as 30-mesh.

CROSSHEADS for sinking buckets in shafts are now made provided with safety clutches.

THERE are several varieties of asbestos, of which mountain leather, a sheet-like variety, is one.

HOISTING ROPES will not endure well if passed over sheaves or wound on drums of small diameter.

IN June, 1899, the price of copper was 18½c. per pound, only a fraction of a cent below the recent high price.

NO SHAFT in which cages or skips are to be run is safe without substantial timbers to carry the guides.

IF the transit is out of adjustment, it is the better plan to send it to the instrument-maker for re-adjustment.

NO MINE SAMPLE is of value which is not representative of the vein at the place where the sample was taken.

THE Supreme Court of California has decided that where an error in the date of a location has been made the facts in the case control.

EACH miner's inch of water under 1,000 ft. head will develop, theoretically, 2.4 h.p. Therefore, 1,000 in. will give approximately 2,400 horsepower.

LIMESTONE is calcium carbonate, often rendered impure by admixture of clay and sand. When containing carbonate of magnesia, the rock becomes dolomite.

WHERE large quantities of gravel or broken rock are to be moved 1,000 ft. or more, it is usually good business to lay tracks and move the material in trains drawn by horses.

A SQUARE ACRE of land measures 208.7 ft. on each side and contains 43,560 sq. ft. In a lode mining claim of statutory dimensions—600 by 1,500 ft.—there are 20.661 acres.

BY 'cap sill' is meant a timber used in the square-set system, which rests at one end in a hitch cut in the foot-wall, the other end resting on a post of the set nearest the wall.

THE alleged absorption of solution by redwood tanks is largely an exaggeration, which is found useful in 'wild-cat' mining when the returns from the cyanide mill are disappointing.

THE courts have decided that mining claims, patented or unpatented, are real property in the strictest sense of the word, and may be taxed, or attached, and are subject to other legal processes.

IT is not advisable to have rock skips made too great a depth, as the impact of falling rock from the chute into the skip wears the bottom very rapidly, particularly if the distance be over five feet.

OXIDIZED COPPER ORES, when rich enough, are commonly smelted, if the necessary fluxes are obtainable. If too low grade to smelt, they may be leached with dilute solutions of sulphuric acid.

UNDER no circumstances should a metal bar be used in tamping powder in a drill-hole. Some States have passed a law making such practice illegal. The chief sufferer is usually the man who uses the metal-bar.

THE cost of producing a pound of copper depends wholly on the mine and its environment. Some mines are so situated as to require high-grade ore to pay. Others can work remarkably low-grade ore at a profit.

WHEN drilling in sandstone the drill-bit should be tapered somewhat and then flattened instead of drawn to a cutting edge. If a chisel-bit is used in drilling sandstone the bit will wear very sharp, and will frequently become fitchered.

THERE are few living streams in the peninsula of Lower California, except in the highest ranges. There are extensive mineral resources, and in several districts mining has been or is being carried on on a large scale. The most noted places are at El Progreso, near La Paz, and at El Boleo, near Santa Rosalia.

CONCENTRATES knows of no mineral veins or ore deposits in that kind of calcite known as onyx, or travertine, and called by some aragonite, though possibly there may be such. These deposits are usually of recent formation, and any vein or segregation of mineral in such deposit is likely to be superficial and of no great extent.

VERTICAL ladders in mines should not extend over 20 ft. without a platform. Where vertical ladders extend for long distances, in cases of emergency, when the men were obliged to climb out of the mine on ladders, instances have been known of a man falling from the ladder upon his comrades below, carrying all to destruction at the bottom of the shaft.

'POT-HOLES' in streams rarely, if ever, prove to be profitable places to mine for placer gold. The probable reason is that gold carried into such holes or depressions is either worn out by the grinding of the sand and cobbles swirled around by the current, or it is carried out of the hole by the rush of the waters. It seems more likely that the former reason is the more rational.

LYDIAN STONE, or basanite, is the touchstone of the jeweler and goldsmith. It is a velvety black stone—a sort of jasper, hard and silicious. Its use is in testing the purity of precious metals, which is determined by the streak made by drawing the metal across the stone making a streak. An experienced workman can form a very close judgment of the fineness of a gold alloy by this means.

FOR fast cutting in drilling, the straight chisel-edged bit is recommended. This style of bit must be carefully tempered, as the cutting is mostly done by the sharp corners, which are likely to be chipped off if there is the slightest flaw. The hammer blows should be sharp and quick. In hard rock a somewhat rounded and rather blunt bit is more economical, though not, perhaps, cutting so fast.

IN returning water from the cyanide annex of a mill to the stamp-battery, it is necessary to be careful about the cyanide in it. The cyanide, if present in sufficient quantity, exerts a selective action on the gold and silver in an ordinary ore; it dissolves the gold and actually precipitates silver on the amalgamating plates. It will also dissolve the copper of the plates and give them a wavy surface hurtful to amalgamation. Not more than five-thousandths or 0.005% cyanide should be allowed in battery water.

WHY a fault-fissure cutting a vein is not also a carrier of valuable ore is difficult to explain. In some instances such crossings, or crossheads, do contain ore, and occasionally they are barren. Those fissures having gangue and other evidences of movement, similar to those found in veins, but destitute of value, are probably of much later formation and may not extend to a depth sufficiently great to reach the zone of deep mineralizing waters which have flowed upward through the ore-bearing fissures.

THE type of riffle used in placer mining and known as the Hungarian riffle is made of strips placed longitudinally in the sluice-box. The slats are secured by stout cross-pieces nailed at each end, with small blocks (two inches long) inserted between the slats near the center to give the whole stiffness and strength. Where the riffle is not longer than six feet, these center blocks are not required. In flumes the Hungarian riffles are made of poles, or scantling, and are sometimes covered with iron to protect the strips from excessive wear. Cast-iron riffles are also in successful use.

HYDRAULIC MINERS say there is a higher efficiency in a single stream of given volume and head from a giant directed upon a bank than when this stream is divided between two giants, under the same head. The common practice is to employ one stream to break down the bank and another to aid in washing away the loosened gravel to the sluices. It is never safe to turn the water into a giant before it is securely anchored. If not firmly anchored it will thrash around, and the lives of all in the vicinity are in imminent danger. A stream from a pipe under 300 ft. is not to be trifled with, and will probably kill a man should it strike him.

SLIME which floats on the surface of the water in vanner-boxes, and elsewhere about mills, may usually be settled by carrying it away from such receptacle through a pipe which is bent downward at the lower end so as to discharge into another box under water. If the pipe be not immersed in water, air is imprisoned in the stream of falling water and slimes pouring into the lower box, and the bubbles of air rising to the surface carry the slime once more to the surface, where it will float again; a baffle-board placed in a settling-tank, which forces the current to pass beneath it, sometimes, though not always, accomplishes the same purpose.

THE first custom smelter in Colorado was built by N. P. Hill at Blackhawk in 1867. It consisted of a calcining furnace and small reverberatory. Every firebrick used in construction was shipped by rail from St. Louis to the terminus of the railroad, and then 600 miles by wagon; all the iron cost 22c. a pound and skilled labor $8 to $10 per day. Smelting charges were $20 to $45 per ton. The matte produced at these works was hauled 600 miles to the Missouri river and then sent by rail to New York, thence to Swansea, Wales, for re-smelting and refining. After being in operation for 20 years at Blackhawk, it was removed to Argo, near Denver.

MANY MINERS, in selecting a site for a tunnel for the development of a mine, make the serious mistake of starting the work too low. It is never good business to start the tunnel too low. While it gives a few feet more 'backs,' this advantage is often offset by the lack of facility in getting the ore into the mill. Where a suitable millsite can be found farther down the gulch, at a point which makes it possible for a tramway to enter the top of the mill at the tunnel level, the tunnel may be run lower than where such millsite is not available. Locate the tunnel, in any event, at such a height that the ore may be trammed directly into the top of the mill or above the rock-breakers.

THE first discovery of gold, which eventually led to the finding of the great Comstock lode at Virginia City, Nevada, was made on May 15, 1850, by a young man named William Prouse, who washed the gold from gravel in a milk pan, near Dayton, at the mouth of Gold canyon. Claims were taken up, and these placers paid $4 to $5 per day to each man, though worked in a crude fashion by inexperienced men. Gold canyon was worked for several years after this, and in the winter of 1858-59 the lode was discovered at Gold Hill by James Finney, popularly known as 'Old Virginny,' after whom Virginia City was eventually named. About the same time Pat. McLaughlin and Peter O'Reilly discovered good diggings on the slope of Mount Davidson—or Sun peak, as it was then called—at the head of Six Mile canyon, nearly two miles north of where Finney had located his claim. The discovery of the McLaughlin & O'Reilly claim led to a much more important discovery of black sulphide of silver in the Ophir claim. Since those days the Comstock lode has produced over $300,000,000, and will probably produce many millions more, as there still remain large bodies of low-grade ore, and possibly also some high-grade ore.

WITH regard to the advantages of ore-bins with inclined bottoms as compared to ore-bins with flat bottoms, it may be stated that with a proper construction of the frame the sloping floor should be amply strong to sustain the weight of the load. The lining of the floor should be of generous thickness, for the stiffness of this part of the structure largely reduces the expense of repairs. Furthermore, the inclined floor should receive a lining of sheet iron, or, preferably steel, under ordinary conditions, but where large quantities of material are being passed through the bins, railroad rails are often employed to furnish a wearing surface strong enough to withstand shock and the abrasive effect of the sliding rock. Such rails are placed side by side lengthwise down the slope of the bottom, the tread of the rail being uppermost. A bin thus constructed, the floor being made to slope at an angle of approximately 45°, will deliver almost any material at the gate and thereby practically empties the bin. The ore that is thus stored is therefore instantly available for use, and can be drawn upon, while with the flat-bottomed bin no ore can be drawn until a sufficient quantity has been introduced to fill up the structure to the angle-of-repose of the material that is being handled, that is, the angle at which the material will run or slide to the gate. Furthermore, if the ore is wet and inclined to stick, the tendency of the inclined bottom is to clear itself, and the packed material is therefore less stable than in the flat-bottomed bin. It will be noted that with the inclined bottom, the angle-of-repose is flatter than with the flat bottom, and the material will run more readily.

UNDER all ordinary circumstances and conditions, 'square-setting' a shaft is preferable to cribbing. The latter is sometimes advisable in soft ground, but not in that which swells upon exposure, for it is likely to crush the timbers unless they are of huge size. In the case of the shaft at Olinghouse, Nevada, if the rock is solid, as described, there is no necessity for cribbing, as the ground will stand without it. The 3-in. scantling being used in the crib—if the crib be solid—will require about 360 ft. board measure to complete 5 ft. of the shaft. If timbered with square shaft sets with 5 ft. from center to center, the two wall-plates, two end-plates and one divider of 8 by 8-in. timber, with a post 6 by 6-in. at each corner, will only require about 180 ft. of timber including blocks, for holding the timbers in place. Lagging may or may not be used, as required. If necessary, use 2-in. plank. In a shaft of the size given this will take about 200 ft. more, if closely lagged—making a total of 380 ft.—only 20 ft. more than are used in the crib, and making a far better shaft. If a pump is to be placed in the shaft, it will require a much more secure support than will be afforded by 3 by 3-in. scantling. It might be a very wise plan to re-timber the shaft from the 110-ft. point to the surface, for the light timber is likely to give trouble and does not make a safe shaft. The 3 by 3's can be used up in many ways, on the surface and underground. Re-timber from the 110-ft. level upward, placing first 'reachers,' resting on hitches cut in the rock for the shaft sets to rest upon. If 8 by 8-in. timbers are employed, the sets may be framed with the 'dovetail,' as in an inclined shaft, which saves some timber and is as good as the overlapping ends when the timbers are properly framed and placed.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

THE BEST SHAPE FOR A SHAFT.

The Editor:

Sir—In Mr. Burrows' article on the best shape for a shaft there are two problems presented, in both of which it is proposed to utilize a 10 by 10 ft. shaft already 320 ft. deep.

In the first case, the data are more or less explicit; the shaft is to be capable of hoisting 1,000 tons per day and of handling an appreciable amount of water. In the other case, a quantity is to be hoisted "larger than possible or advisable for two hoisting compartments." Unfortunately, the article does not even approximate *how much* is to be hoisted and one has to guess arbitrarily at the amount.

The question of the probable life of the mine and the richness of the orebody to be served is a factor that enters strongly into the problem of utilizing the whole of the present shaft, and it is quite possible that the saving (if any) to be effected by this may be comparatively so inconsiderable as not to be worth taking into account. In other words, it should be borne in mind that the first point in contemplating a work of such magnitude is to design a shaft that will effect a maximum of efficiency at a minimum running cost when completed and this ultimate object should not be influenced by any "penny wise and pound foolish" policy.

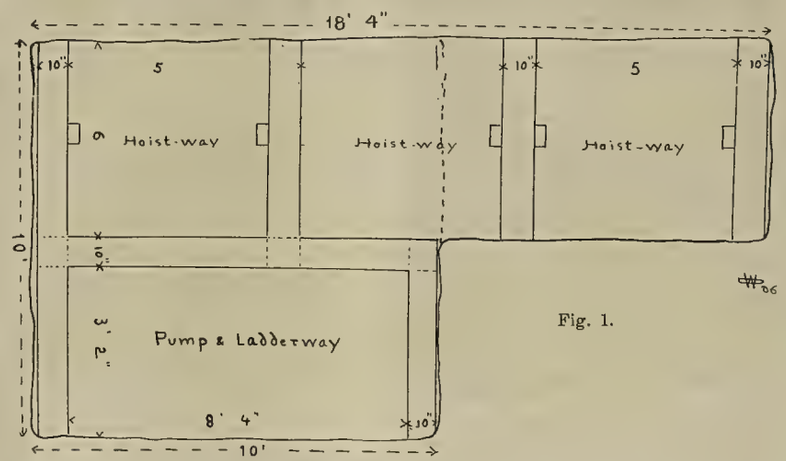

Fig. 1.

Assuming, however, that the old shaft *must* be utilized and considering the first case, it becomes obvious that, partly for the very reasons referred to in Mr. Burrows' article and partly because in a well-equipped and modern vertical shaft with proper platformed ladderway, it is out of the question to hoist and lower material in the latter compartment. The 'jog' idea must be summarily discarded.

It is stated that the old shaft will allow 6 by 10 ft. for two hoisting compartments and 4 by 10 ft. for ladderway and pump. It is hard to conceive of a shaft of such a daily amount of ore to be constructed without properly framed sets, but, admitting that the wall-plates are unnecessary, there remain the dividers and end-plates, which would probably be at least 10 by 10 in. in section. Allowing also for guides 4 by 6 in. and 2 in. for clearance, this, then, would provide only for two hoisting compartments with skips whose greatest possible width would be only 2 ft. 11 in., though, of course, a length could be obtained of 5 ft. or even more. The ladder and pump compartment would then be 4 ft. 2 in. by 8 ft. 4 in. Even using 8-in. timbers, which would not usually be considered adequate for the purpose, the skips (cages would be out of the question) could only be 3 ft. 1 in. wide.

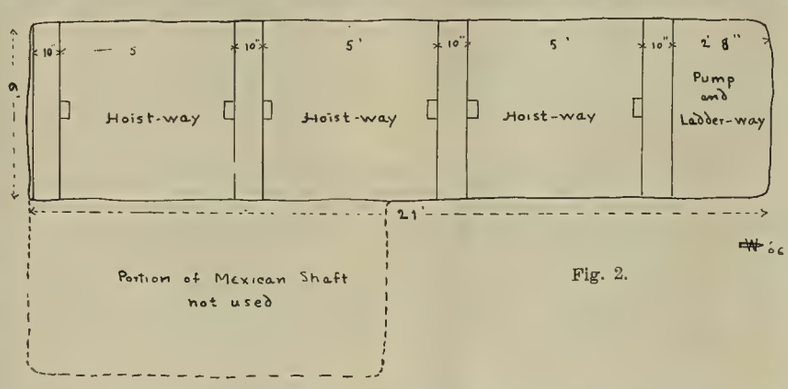

Fig. 2.

At the practical average rate of hoisting these skipways would be inadequate, particularly so, were more than 1,000 tons per day required to be produced. Therefore, the shaft will have to be enlarged, but *how*, is the question. Obviously the 'jog' theory must be discarded. The sketch in Mr. Burrows' article called "manager's proposal," although utilizing all of the old shaft, provides for an unnecessary large sectional area to be excavated. The pump and ladder compartment do not require such a space and with four hoisting compartments there are four separate points of loading and unloading and two hoisting engines, which must be run more or less all the time, thus wasting labor. In solution, I submit two designs. The first provides for the utilization of the whole of the old shaft, and when 320 ft. has been reached the shape of the excavation would be represented by Fig. 1, not a convenient one for either drilling and blasting or removing muck. Therefore, I believe that Fig. 2 shows as advantageous, economical and efficient a shape as can be put forward, and the larger part of the old shaft is utilized.

In both cases, I am assuming that wall-plates are *not* necessary but that end plates *are*. The extra portion to be excavated down to 320 ft. could be removed, either by sinking from the surface or by raising up from the bottom—probably the latter method would be preferable. Here it will be noticed that a four-compartment shaft is designed, with three hoisting compartments and a pump-and-ladderway. The two end hoisting compartments should be amply sufficient for 1,000 tons per day and the extra compartment would be available for an automatic bailer in times of need, which could be readily exchanged for a skip when the ore supply got beyond the capacity of the other two compartments.

It is true that an extra single-drum hoist would be necessary for this compartment, and though perhaps not so economical as the counter-balance engine, which would probably be used at the two other compartments, it is not likely that it would be in use more than a small proportion of the time and there should be no loss in extra labor.

D'ARCY WEATHERBE.

DISTRIBUTION OF ORE.

The Editor:

Sir—The editorial comment upon my first article on 'The Ontario Mineral Belt,'* in which I set forth the influence of the several geologic formations upon the occurrence of the ore in the veins and lodes, and also the cause of the selective deposition in certain beds, makes it evident that some features require explanation. It is thought that the solutions which deposited the mineral in the Ontario and Daly lodes were of different chemical composition from the solutions replacing the limestone in the formation of the bedded deposits. Let us consider first the extensive flat deposits in the 'gray limestone,' which occur irregularly distributed over an area 700 to 1,000 ft. broad and a mile long, in the Daly-West and Daly-Judge mines. The 'gray limestone,' which constitutes the favorable ore-horizon, is 25 to 35 ft. thick and rests upon a floor of quartzite. It is a hard crystalline rock, readily fractured by even slight crustal movement. The way this limestone was removed and the ore substituted in its place, is evidence that the rock was easily soluble in the waters depositing the ore. But why was this particular bed alone selected from a geological section of quartzite, shale, and limestone more than a mile in thickness? Prof. John A. Church, discussing the deposition of ores in limestone, says: "The operation of solutions whose composition we do not know can be judged only by their effects. When metasomatic replacement takes place in limestone, it is generally assumed that lime-carbonate goes into solution, its place being taken by the ore-substances. Limestone contains the elements for self-destruction, since the breaking up of one lime-carbonate molecule may cause the solution of another (by the carbonic acid set free); and, as this cannot be said of any other rock, we reach a possible explanation of the comparative frequency of orebodies in limestone. Ore-solutions exhibit a selective power which is extraordinary in a water fully supplied with dissolving qualities, but quite explicable in a solution which lacks that power."† The solutions that deposited the ore in the gray limestone ascended through fissures which connected with a source deep-seated in the igneous core of the Uinta axis, and in their up-flow traversed many thousand feet of sedimentary strata of widely variable mineral composition; yet they do not appear to have formed deposits in any place until they reached that favored horizon. My investigation of mineral formations in limestone, in other parts of the Great Basin, led me to believe that at the time the deposition took place, there existed a union of singular structural, physical, and chemical conditions in the special beds in which the ore occurs; that the solutions were, relative to the rock, chemically active, and that dynamic conditions that caused the shattering, cracking and fissuring of the strata, influenced the localization of the deposits. Analyses of the magnesian limestones over a broad belt at Tintic district, Utah, show that they vary but little in composition, and that eliminating the impure sediments, which seldom carry workable deposits, the structure of the rock appears to be far more important than the chemical composition in determining whether certain strata are ore-bearing or barren. In the Ontario belt the conditions are the reverse of those at Tintic; the prevailing limestones, without regard to the age of the geological formation, are impure and only occasional pure beds occur in the great thickness exposed. It is significant that the gray limestone, which constitutes the favorable horizon in the mines at Park City, is so pure that little sediment results from its dissolution. If structural conditions controlled, the quartzite on which the gray lime rests would also carry ore where broken and fissured—but the crushed masses of quartzite which occur are barren. In a few places, calcareous layers in this quartzite are observed to be replaced by ore. The evidence of the deposits in the gray limestone supports the view that the solutions were acid or neutral, poor in silica and with free carbonic acid in excess; that they were inert to quartzite and to all rocks in the series, other than pure calcareous sediments. The gray limestone is not alone ore-bearing; in the Crescent mine, on the northward flank of the Ontario belt, there occur eight distinct horizons, in the black limestone, that carry workable deposits.

In the case of the Ontario and Daly lodes, the character of the wall-rock influenced the localization. This action is due mainly to the fact that the material filling the fissure, which constitutes the gangue, is fragmental rock derived from the vein-walls. Owing to the vertical movement of over 500 ft., in the creation of these fissures, the rock-filling is dragged for some distance, especially where the lode is broad. Where the vein passes on the dip from one geological formation to another, the gangue is for this reason a mixture of the different rocks, and in consequence its favorable or non-favorable character for ore is affected. The nature of the wall-rock, and especially its mineral composition, influences the character of the gangue. This is shown where the walls of the lode are shale, which by its decomposition produces a clay gangue, impervious to the circulation of the mineral-bearing waters. Quartzite, on the contrary, yields an open permeable fissure-filling, in every way favorable for the deposition of the ore.

Secondary deposition alone has not been the cause of the occurrence of rich ore in the Ontario lode between the 250 and 1,050-ft. levels. The vein only goes to the surface in a few places, and the amount of ore removed by erosion has probably been limited. Oxidation and secondary enrichment are confined to the Ontario quartzite in vertical range and can in no way affect the question.

THE BEST SHAPE FOR A SHAFT.

The Editor:

Sir—I am tempted to say a word in answer to R. H. Burrows' request, that his letter on the above subject "provoke some remarks from those of the mining fraternity." I judge from his letter that he favors the 5 by 16-ft. shaft, and from my personal experience I believe he has good reason on his side.

The following are the several points in favor of the rectangular shape shaft: First—Supposing it were to be sunk with machine-drills; it would be convenient to work two or three cross-bars, with a machine on each bar, this length of bar (4 to 4½ ft.) would be easy to handle and a round of holes could be drilled in a short time. Second—The timbering question would be simple, for the length of timber

would be such, that the cost would be close to the minimum; the timbers themselves would be easy to handle and put in place. This is an item that should not be considered lightly, for in many localities timber is scarce and expensive. Third—The economy of the 5 by 16-ft. shaft over the 10 by 10 as to breaking of ground, shoveling and hoisting dirt, may best be shown by a few figures; suppose the new shaft were started at the bottom of the old 10 by 10 shaft, which is down 325 ft., and it is intended to sink to the 2,300-ft. mark. The 5 by 16 has a bottom area of 80 sq. ft. against 100 sq. ft. of the 10 by 10; in sinking the 1,980-ft. (2,300–320) there would be removed 158,400 cu. ft. of rock in the former against 198,000 cu. ft. in the latter; a difference of 39,600 cu. ft., or 3,046 tons (allowing 13 cu. ft. to the ton). I shall not press the point further, by estimating the costs, etc., for they would be widely different for different districts. This item alone would not be of great importance were the 10 by 10 shaft better in every respect or did it show a marked advantage over the 5 by 16; I cannot see where it does, from Mr. Burrows' letter. As Mr. Burrows states, in shaft work it is not the difficulty experienced in accomplishing rapid drilling, but in handling the broken rock rapidly and getting it to the surface; a 'mucker' using a short-handle shovel can do as much work in the 5 by 16 shaft as he can in the larger one. Fourth—I should say that the 5 by 5 compartment for the pump and ladderway would be sufficiently large for all ordinary purposes; as a rule pipes for the pump, rails and timbers are sent down in the regular cage or bucket during stated periods in the day or night time, when both hoisting compartments are not working on ore. It would be a very simple matter to run timbers and pipes through openings, made between the sets into the pump compartment. Fifth—As for the 'jog' (where the new shaft started from the old one), that is not a serious feature, for it could be beveled off for a distance of 20 or 25 ft. in height, so it would cause no trouble, except possibly, in lowering materials through the pump compartment; that, however, is not necessary, as stated above. Sixth—I see no reason why there should be any difficulty in handling the desired tonnage (1,000 tons) with the two compartments, provided the hoisting equipment and the underground loading facilities were good; should it be advisable to greatly increase the tonnage, in the future, to say 2,000, 3,000 or 5,000 tons daily, would it not be better to sink one or more new shafts at other points? In that way a good system of ventilation could be established when connections were made. This is the scheme practiced by large companies throughout the world; mines, such as the Little Johnny at Leadville, the Portland at Victor, Colo., those of the Lake Superior region, and in fact in many other camps throughout the United States.

As Mr. Burrows states, it is the custom in every country to sink shafts of rectangular shape in preference to square shafts (this applies to shafts of the larger sizes). Every engineer and superintendent has his well-founded reasons for doing so, consequently there must be a decided advantage in the former. I have given a few points that have come within my experience; undoubtedly, letters from men of wider experience will be published by you, and I believe that each will refer to points in favor of the rectangular shaft that I have not mentioned.

Such subjects, as this pertaining to the practical end of mining, are very interesting and beneficial to all concerned in the business, and I believe that if more men who are actively engaged in mining, would express their ideas on the different subjects published under the head of 'Discussion,' it would be beneficial to themselves, as well as to the profession.

H. R. Plate.

Denver, March 2, 1906.

Black Sand of the Pacific Slope.

In accordance with an act of Congress, the Survey sent a circular, in 1905, to all the placer miners of the United States (about 8,000), inviting them to send to the Geological Survey samples of the heavy sands collected in placer gold mines. More than 1,000 such placer miners promptly responded with samples, which were at once assayed for gold and platinum. Further, these samples were scrutinized closely to detect the presence of various other minerals which have become industrially useful within the last five years. Among them are chromic iron ore, for the manufacture of paints, chrome steel and bichromate of potash; monazite and zircon, for the manufacture of incandescent gas and electric lights; magnetic iron ore, for the manufacture of steel; and especially tantalite and columbite, which have recently become very valuable in incandescent electric lighting. By reason of the prompt responses from the placer miners it was possible to examine sand from 34 States and Territories. It was quickly recognized that the distribution of valuable minerals in these sands is vastly greater than had previously been supposed. In addition to the useful minerals mentioned, considerable supplies were indicated of such valuable minerals as corundum, cinnabar (quicksilver ore), tin ore, garnet, and others. It was found that platinum occurs at many localities where its presence had not been suspected, and the majority of the specimens were found to contain gold in appreciable amount which it had been impossible to extract, either because the gold is very finely divided ('flour gold'), or because it is coated with iron oxide or other materials which prevent amalgamation (rusty or black gold).

The Victoria Bridge. (See Page 163.)

In order to determine whether these valuable minerals could be extracted at a profit, a number of concentrating machines of the best types were assembled at Portland, Oregon; for Portland proved the most central point for collecting the necessarily large quantities of these sands, and during the dry season, when the placer miners could not work, they could assemble at the Exposition and note the results obtained. The Geological Survey retained Robert H. Richards, dean of the mining school of the Massachusetts Institute of Technology, for a study of the extraction of these minerals.

It was quickly found that from 95 to 98% of the gold and platinum could readily be extracted from the black sand simply by concentration on tables of the Wilfley, Pinder, and Woodbury types. It had been expected that the sand would require preparation for these tables by a special machine known as the hydraulic classifier, but this machine proved unnecessary, inasmuch as the sand of the sea beaches and the heavy sand from sluice-boxes, from which the valuable ingredients, such as fine gold, rusty gold, and the useful minerals alluded to above, could not profitably be separated, proved to be in the best condition possible for separation on tables. The railroad companies of the West co-operated by free transportation of many carloads of sand to the Survey's plant at Portland.

These concentration experiments attracted very much more attention than was expected from the placer miners. Concentrating tables had never been used in placer mining to any extent, but many hundred mines are now being equipped with machines of this character. Several thousand miners visited the concentrating work during the summer, and they were generally convinced that these methods would apply to some sands, but not necessarily to their own; therefore many of them asked and received permission to submit samples of their sands as soon as the rainy season would afford water for collecting them. As the minimum amount of sand necessary for such concentration was 100 lb., and many of these mines are situated from 50 to 100 miles from a railroad or even a wagon road, the miners went to much expense to collect samples.

The Victoria Falls of the Zambesi. (See Page 163.)

Cost of Cables.—It appears that there are some 225,000 miles of cable in all at the bottom of the sea, representing $250,000,000, each line averaging about $1,000 per mile to make and lay. The average useful life of a cable nowadays may be anything between 30 and 40 years, according to the circumstances. About 6,000,000 messages are conveyed by the world's cables throughout the year, or 15,000 a day, the working speed for any one cable being up to 100 words per minute under present conditions. About 90% of these are in code or cypher for business and official purposes.

The Grand Central-Mammoth Decision.

These mines in dispute are situated in the Tintic district, Juab county, Utah, about 70 miles southwest from Salt Lake City. The Mammoth and Grand Central mines are on the western slope of the Tintic mountains, at an elevation of 6,000 to 8,000 ft. A great thickness of carboniferous limestone, two miles across, upturned and extensively faulted, constitutes the prevailing productive country. This limestone area is surrounded on the north, east and south by igneous rocks; on the west side the sedimentary formations dip beneath the gravel deposits covering the desert. Tintic district, it may be recalled, has been recently cited by W. P. Jenney as an example of block-faulting due to repeated volcanic disturbances.* A peculiar fault or clastic dike cuts through the mountain and traverses the ground in controversy. It is known as the Finn dike. A branch-fault which departs from it is called the Coates dike. These 'dikes' are frequently referred to in the decision. It should be understood that they are fault-belts, zones of brecciation, and not in any sense intrusive or igneous in formation, save that they were created by movement following upon the volcanic upheaval of the region. These dikes are not in themselves ore-bearing; although in the Mammoth mine the Finn dike is intersected by younger fissures carrying ore, which form deposits in the midst of the dike. The influence of the Finn dike in the deposition of the mineral; how, in the early working of the Mammoth mine, the dike was looked upon as the west boundary of the ore-bearing ground, and the attempt to utilize it, as a component part of the broad lode claimed by the Mammoth witnesses, are fully set forth in the decision. The position of the limestone beds, relative to the strike and dip of the lode in the several blocks of faulted strata traversed, also influenced the deposition of the ore. Thus, in the large block lying east of the Finn dike, the strike of the beds is northwest and the dip 35° northeast; the vein WU (see Fig. 1) cutting the beds on both strike and dip. In the smaller block between U and T, the vein UT conforms to the bedding, having a strike north 75° west, magnetic, and a dip 70° north. The great block in which occurs the Grand Central mine, situated west of the Coates dike, is formed by beds of limestone striking west of north in the direction of TS and dipping 75° west, the vein TS being nearly conformable to the stratification.

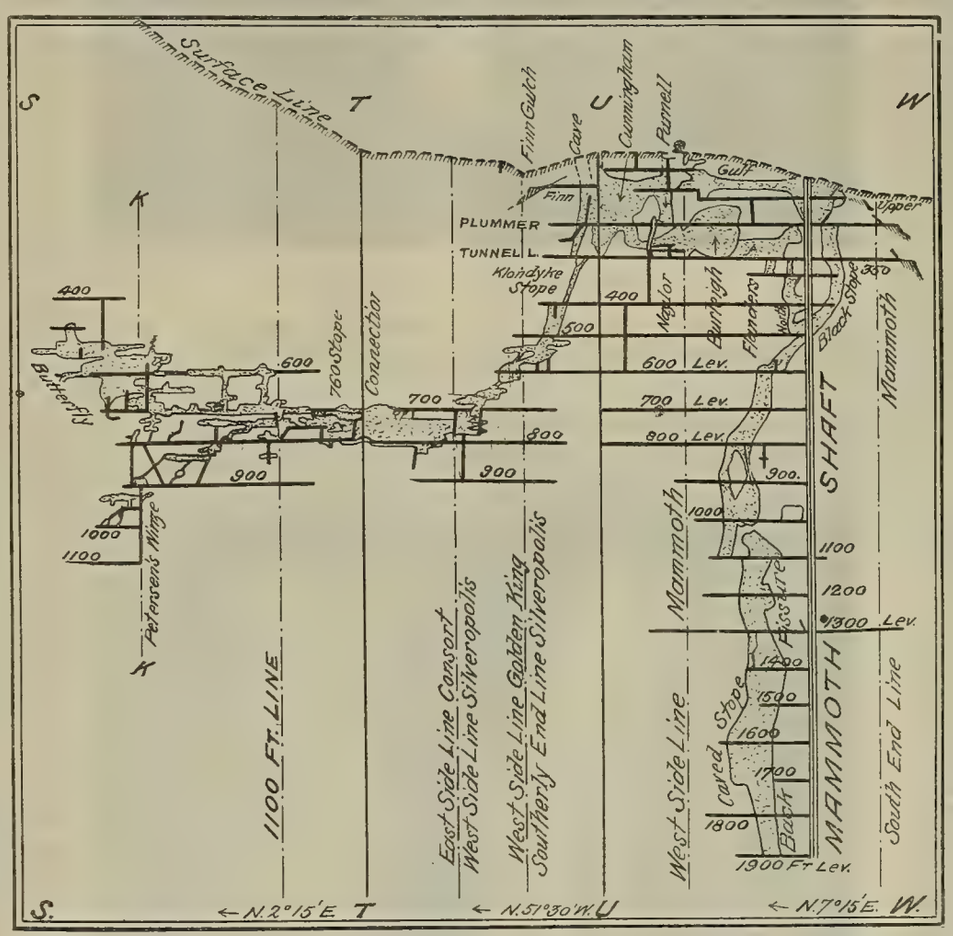

Fig. 1. Projection of the Grand Central and Mammoth Mines, on the Planes WU, UT and TS.

The plaintiff insisted that the projection on this plane exposes the vein on its strike and dip, while the defendant contended that its dip only is exposed, and that its strike is parallel to the side-lines of that lot.

The Grand Central claimed a fissure vein, modified by the nature of the wall-rock, having a course indicated by the stopes, following the lines WU, UT, and TS. The ore occurred in places in a more or less tabular form within the fissure; more commonly the solutions depositing the mineral attacked the limestone, and the ore formed irregular deposits, both within and without the fissure. The witnesses for the Grand Central maintained that the limits of the ore were the limits of the vein. It is not easy to describe the contention of the Mammoth—the broad zone of fractured and crushed country rock, taking in practically all the orebodies of the two mines, which included within the breadth claimed immense masses of non-mineralized limestone, that were in no essential way different from the limestone prevailing throughout the district. In the leading case involving the 'broad lode' theory, the Eureka-Richmond decision, the zone of mineral-bearing limestone was enclosed between a foot-wall of quartzite and a hanging wall of shale. But in the ground here in conflict, all such natural boundaries to the lateral extension of the mineral in its deposition were absent. By reason of this want of natural boundaries for their broad vein, the witnesses for the Mammoth were in difficulty to define in any place the breadth of the zone they claimed, or to fix the position of either its foot or hanging wall. The court quotes very fully the testimony of the witnesses for each party upon these issues. There were other difficulties: the Mammoth claimed that the lode apexed in the First Northern Extension of the Mammoth, Lot 38, from the south end to the 1,100-ft. line, and beyond, for no evidence was offered by the Mammoth that the apex anywhere departed from the mining claim. An inspection of Fig. 2 will show the line of stopes in the Grand Central mine rapidly diverging from Lot 38 to the west and northwest, so that any vein apexing in Lot 38 would have an almost flat dip, to include the orebodies in the Grand Central, north of the 1,100-ft line. And this in the face of the fact that the attitude of the vein in these mines, as shown by the stopes, is near vertical, the ore-bearing fissures conforming generally to the bedding of the limestone. In the ground in controversy, the strata-blocks are upturned on edge, so that any vein or lode, with dip assumed to approach horizontal, must cut the bedding. Further, the Finn dike is a normal fault, with downthrow on the west, or an upthrow on the east, (it matters not which, the relative displacement being the same). Evidence was offered by the Grand Central to show that a fault movement of 400 ft. vertical had taken place since the ore was deposited, whereby the country west of the dike, in which the Grand Central mine was situated, was relatively depressed, with respect to the ground east of the dike, where Lot 38 is located. And that at the time the deposition occurred, the top of the orebodies in the two mines was in the same horizontal plane; a fact which, if admitted, precluded the occurrence of any vein in the mammoth entering the Grand Central ground on the dip, or entering in any way save on the strike.

The Mammoth mine was discovered about 1870, and at the time of the trial in 1901, the production was stated to be $8,000,000. That of the Grand Central, for the few years the mine had been worked, aggregated $1,800,000. The ores vary widely in mineral character in the different orebodies in these mines, partly due to difference in original deposition and partly to subsequent oxidation. There are large bodies of quartz carrying gold with a variable amount of silver; also masses of high-grade copper ore associated with silver and occasionally of similar ore in which silver is absent; other bodies are mainly silver-lead ore. The mines are dry; no water has been encountered in the Mammoth from the surface to a depth of 2,200 feet.

In the Supreme Court of the State of Utah. Grand Central Mining Company, Respondent, vs. Mammoth Mining Company, Apellant. The plaintiff commenced this action in September, 1899, by filing a complaint in trespass, in which it alleged that the defendant had unlawfully mined and removed, from beneath the surface of the Silveropolis mining claim, ore exceeding the value of $300,000.

The defendant filed an answer and counter-claim subsequently amended. [These pleadings raise essentially the same issues as are decided in the second trial, here reviewed.—Editor.]

Upon the trial of the case, the court found that the vein, at its apex and on its strike did not continue within Lot 38 to the 1,100-ft. line, but that the apex passed over the westerly side-line of that lot and departed therefrom, at a point 700 ft. north of the south end-line of the lot, without again returning thereto, and dismissed the defendant's counter-claim.

Afterward, in April, 1901, another judge, presiding as successor to the one before whom the case had been tried, granted a new trial.

On November 20, 1901, the defendant filed its third amended answer and counter-claim, in which it alleged that the vein and lode at its apex and on its strike crossed the south end-line of Lot 38, and thence continued north in that lot to the 1,100-ft. line; that the apex of the vein was very broad, its width extending east of the east side-line of Lot 38, and overlapping portions of the Young Mammoth, Jenkins, Schley and Boss claims owned by the defendant; that its apex likewise extended west of the west side-line of Lot 38 and overlapped portions of the Jenkins, Golden King and Bradley claims, also owned by the defendant; that at no point south of the 1,100-ft. line did the apex wholly depart from Lot 38, the lode upon its course conforming to the side-lines of the lot; that Lot 38 was the senior location and long preceded all the other mining claims mentioned in the counter-claim; and that the vein on its dip to the west departed from the side-lines of Lot 38, passed under and beyond the surface limits of the Jenkins, Golden King and Bradley claims, and extended, at a depth of 700 ft., under the south end-line of the Silveropolis mining claim, further on its dip to, and beyond, the limits of the Silveropolis and Consort claims, and embraced all the orebodies lying underneath those claims south of the 1,100 ft. plane. The prayer was that the defendant's title to those orebodies be quieted against the adverse claim of the plaintiff.

To this counter-claim, the plaintiff answered, alleging that it was the owner of the Silveropolis and Consort claims, and of all the veins and ores therein or thereunder and within planes extending down vertically through the boundary lines of these claims. On the issue thus formed the case was again tried. A jury was empaneled advisory to the court to pass on certain issues.

The trial commenced Nov. 21, 1901, and lasted 70 days. The only issues tried were those formed by the defendant's last counter-claim and the answer thereto. The defendant introduced a vast amount of evidence for the purpose of showing that the vein or lode continued at its apex and on its course within Lot 38 from its south end-line to, and beyond, the 1,100-ft. line, and that the same was continuous on its dip to, and beyond, the Silveropolis and Consort claims, and embraced all orebodies found in either of those claims lying south of the 1,100-ft. plane.

Respecting the width, or exterior limits of the vein, Wm. A. Akers testified: "The boundaries of this vein would be the limits of the fracturing which had occurred and been produced by the dynamic forces exerted in creating the vein. Q. And so far as that fracturing extended, so far you would claim your vein extended? A. Plus any additional width of ore or vein-matter that might be produced by metasomatic change. Q. Would you claim that the limits of your vein were coincident with the limits of the fracturing? A. No, sir; not where replacement had changed the limits of the fracturing. Q. Would you claim that your vein extended at least as far as the limits of the fracturing? A. Yes,

*"Block-Faulting and its Relation to Ore Deposition." MINING AND SCIENTIFIC PRESS, page 54, Jan. 27, 1906.

Fig. 2. The Principal Stopes of the Grand Central and Mammoth Mines.

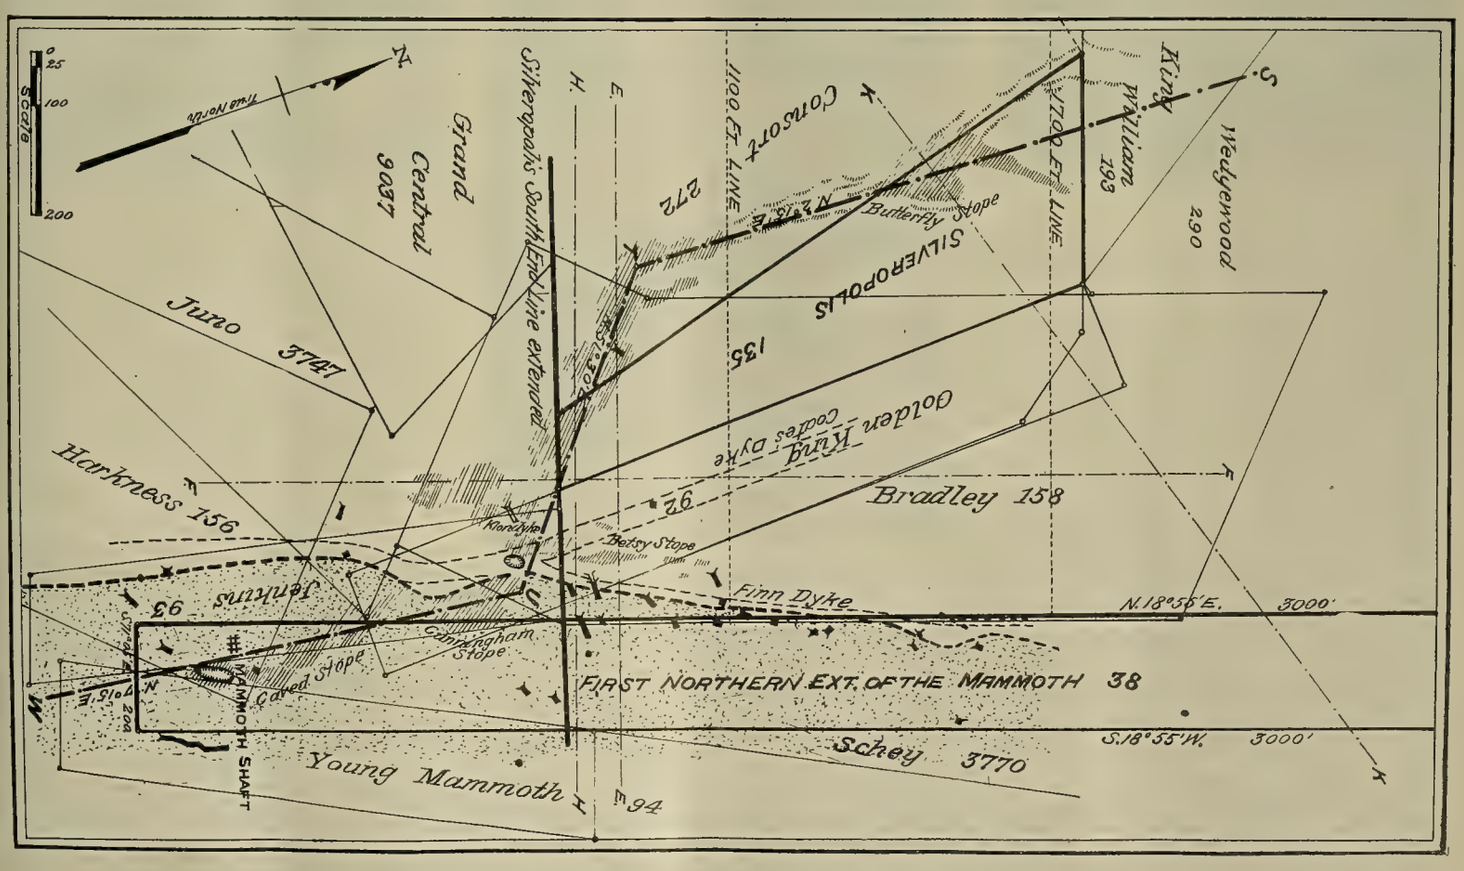

Fig. 3. Surface Boundaries of the Litigants in the Grand Central-Mammoth Case.

sir." The witness also stated that the vein was a "fissured section of limestone," and the witness, Watson, testified that, as he understood it, the vein was "bounded by the fissuring," and that "if the fissuring were all connected" and "extended 4,000 ft." he would say the vein extended that far. He could not determine from the developments on any level whether any of the workings extended beyond the foot-wall boundary of the vein.

From the testimony of Samuel McIntire, it appears the vein, as shown by the developments, on the 900 level is nearly 900 ft. wide, on the 700 level 1,050, and on the 600 level 1,020 ft. in width.

Walter P. Jenney says: "I consider the limit of the vein to be the limit of the mineralization."

James Talmage testified: "The boundaries of this orebody or vein, throughout its entire extent, would be determined by the nature of the mineralized matter, using the term, as indicating ore matter when it carries valuable metals to an amount in excess of the valuable metals carried by the country rock."

Walter P. Jenney, speaking of the Finn break, said: "In the first movement the rocks were shattered and broken up into large pieces, many feet in dimensions, and lines of sheeting or fissuring parallel with the dike were made through the rocks adjacent to the fissure. Then, as the movement continued, these masses of rock were pulverized more and more —more and more broken. It is very irregular in width, in some places only 15 ft. wide, in other places it would expand to 30, 40 or 50 ft. in width; where it united with the Coates dike on the south, it is possibly 100 to 125 ft. wide. The dike appears to have grown from its eastern side toward its western. On the eastern side, which would be its foot-wall, we find a heavy, tough stratum of clay; that is due to the grinding movement of one wall moving upon the other."

Sidney Tyler, referring to faulting, testified: "I think that there has been movement along the line of the foot-wall of the Finn break and on different parallel slips, included within the Coates dike, which has resulted in the dislocation of the orebody in a dropping of the orebodies lying west of the dike to a position anywhere up to 400 ft. or so, lower than that formerly occupied before the faulting took place."

The case was thus submitted to the court, and the jury returning a verdict upon the special issues, in favor of the plaintiff, the court adopted the verdict and found, agreeably with it, that the top or apex of the vein continued, from the south end-line of the first northern extension of the Mammoth, Lot 38, to the place where the Cunningham stope at its north edge or end crossed in its northwesterly course the west side-line of that lot, such point or place being, as found, 690 ft. north of such south end-line, and 90 ft. south of the south end-line of the Silveropolis mining claim, extended east in its own direction across Lot 38; that at that point the vein on its strike and at its apex wholly departs from Lot 38, and does not continue within that lot between the planes drawn through the Silveropolis south end-line extended, and the 1,100-ft. line; that such apex does not continue north of such end-line within the limits of Lot 38; that between such planes on that end-line so extended, and on the 1,100-ft. line, there is no apex of any lode which on its dip extends to and includes the orebodies known to exist beneath the surface of the Silveropolis and Consort mining claims, between those planes; and that the apex of the lode, which is in the south end of Lot 38, does not continue in that lot north of the Silveropolis south end-line extended.

Notwithstanding this decision, which was substantially the same as that at the previous trial, the judge filed a written opinion, in which he concluded that there are two veins in the Mammoth ground, and he argued that the orebodies in controversy belonged to a vein which had its apex in the Golden King and Bradley mining claims, and could be recovered by the defendant in a proper proceeding. Thereafter the defendant asked leave to amend its counter-claim, and later to file an original counter-claim, in accordance with the expressed views of the court. These requests being refused, the defendant prosecuted its appeal.

After stating the case, Chief Justice Bartch delivered the opinion of the court:

The main question is, whether the court erred in finding that the vein at its apex and on its northwesterly course crosses the western side-line of Lot 38 and wholly departs from that lot at a point 690 ft. north of its south end-line, and north of that point does not continue either at its apex or on its strike to or beyond the 1,100-ft. line within the limits of Lot 38; and that there is no vein having an apex or any part thereof within the limits of Lot 38 north of the south end-line of the Silveropolis mining claim extended eastward in its own direction, and south of the 1,100-ft. line, which, on its dip, extends to and includes any of the orebodies existing underneath the surface of the Silveropolis and Consort mining claims, south of the 1,100-ft. line.

In determining this question the surface of Lot 38, the extra-lateral rights of that lot, the dip and strike of the vein, and the underground workings of the mines are important factors. The extra-lateral rights, upon which the appellant has founded its claim to the orebodies in dispute, accrued to it as owner of Lot 38, by virtue of the provisions of Section 2,322 of the Revised Statutes of the United States, whereby the owner of a mining claim has a right to follow, between vertical planes drawn downward through the end-lines of the location, a vein, having its apex within the limits of such claim, on its dip to the deep, although such vein may so far depart from a perpendicular in its course downward as to extend outside of the vertical side-lines of the surface location. The orebodies in controversy, however, being situated without the limits of Lot 38, and underneath the surface of the Silveropolis and Consort mining claims, the appellant, notwithstanding the law of Congress, is met at the very threshold with the presumption that they belong to the respondent, the owner of those claims. Where a person owns a patented mining claim, although the statute reserves the right to locators of other mining claims to follow their veins under its surface and extract ore, he is presumed to own all the ore within planes drawn vertically downward to the deep through the boundary lines of such claim, as well as the surface and everything else appurtenant to the claim; and such presumption continues until some other locator or owner establishes the fact that he is entitled to exercise the reserved rights by virtue of the statute. "Within the lines of such location the owner shall be regarded as having full right to all that may be found, until some one can show a clear title to it as a part of some lode or vein having its top and apex in other territory. To state the proposition in other words, we may say that there is a presumption of ownership in every locator as to the territory covered by his location, and within his own lines he shall be regarded as the owner of all valuable deposits, until some one shall show by preponderance of testimony that such deposits belong to another lode having its top and apex elsewhere."

To overthrow this presumption and establish its rights to enter its neighbor's ground to extract ore the burden of proof was upon the defendant, and it was incumbent upon it to show, by a preponderance of the evidence, not only that the apex and strike of the vein were in Lot 38, north of the south end-line of the Silveropolis mining claim, extended, and to the 1,100-ft. line, but also to show that, between planes drawn vertically downward through that end-line and the 1,100-ft. line, the vein, from its apex, on its dip, was continuous; that its continuity extended to, and through, respondent's ground; and that the orebodies in question formed a part of the vein.

We concede, as claimed by the appellant, that a patent to a mining claim raises a conclusive presumption that there is the apex of a vein within the patented ground (1 'Lindley on Mines,' Sec. 305); but there is no presumption that it is the apex of the vein in dispute, and such presumption applies equally to the Silveropolis and Consort mining claims as to Lot 38, and does not shift the burden of proof in this case.

Respecting the geological features of the country in which the properties are situated, there is practically no conflict. It is shown that the mines are found in a lime belt that covers about two miles square, and is the great producing area of the Tintic district. In some places the limestone beds are upturned, large areas tilted upon edge, the beds dipping nearly vertically, while in other places they dip at lower angles, and in special areas the dips are quite uniform, and again, though, it seems, not frequently, anticlinals exist. This limestone is surrounded on all sides, except the west, by igneous rocks. The sedimentary rocks are broken up and fractured, evidently the result of igneous intrusion. The limestone carries the different forms of iron oxide, also some manganese, and, in places, the limestone is crushed, crumbled and brecciated. How these beds of sediment were dislocated, bent and upturned, is not free from doubt. Whatever the cause, the disturbance is apparent from the evidence. The surface of the limestone area, wherever exposed, is marked with innumerable seams, cracks and small fissures filled with carbonate of lime. Quartz, spar, and other materials, characteristic, in general, of mineral-bearing limestone areas, are present, and, in places, the surface material is brecciated and recemented. A trace of mineral, of one or more of the precious metals, and, in places, more than a trace, even where there is no known vein, seems also to be characteristic of that lime belt. The witnesses for the appellant, who had examined the surface and open-cuts as well as the underground workings of the mines, testified, in general, that the fractured, stained and brecciated conditions appeared to such an extent upon the surface and in the open-cuts of Lot 38 as to furnish unmistakable evidence of the apex of a vein; that the vein was so clearly defined upon the surface, and so distinctly differentiated from the adjacent country, that its boundaries could readily be traced throughout the length of that lot, and be recognized by mere observation; and that the indications showed the apex to be so wide that it overlapped the side-lines of that claim.

The leading witness for the defendant, William A. Akers, an expert of much scientific knowledge, after testifying that the Mammoth was a fissure vein, and that it was not an individual fissure, but consisted of a series of approximately parallel fissures, or breaks, in the fractured mountain, said: "Taking this individual vein; this broad, beautifully defined fissure that I personally have traced for a distance of between three and four thousand feet on the surface, we find that it is clearly defined on the surface, and so clearly and distinctly differentiated from the adjacent country that I could identify all points generally along the course of that vein. I could stand at one end and as far as the configuration or topography of the country permitted, see how that vein ran; and to guide me in the other direction, namely the southerly, a portion of the ground not in controversy at all, I could see the vein there through extensive workings for say a thousand or two thousand feet."

While the defendant's witnesses are emphatic in asserting an apex in Lot 38, and clearly defined differentiation of the surface of that lot from the adjacent country, none of them attempted to locate upon the surface, or fix the hanging or foot-wall of the vein, north of the Silveropolis south end-line extended, nor north of that point at the Cunningham stope where the court found the vein departed from the lot, and yet, if its differentia be so clear that, "to recognize its boundaries," one, as claimed by Mr. Akers, need but look at the surface, aside from the open-cuts, the query naturally and logically arises why, in a controversy of this magnitude, its vital and decisive point—the apex of the vein—was not traced and definitely fixed within the disputed territory. Why was such a point left to mere conjecture, to mere inferences from disputable surface appearances? The only answer, which this voluminous record affords, comes from the witnesses for the plaintiff, and that answer has the support of the findings of the court. These witnesses say, with at least equal emphasis, that no such differentiation exists; that there are no indications of a vein or apex on Lot 38 north of the point where the Cunningham stope crosses its west side-line, which is about 90 ft. south of the Silveropolis south end-line extended; that, apart from the dike material, the limestone, north of that point, within Lot 38, is not any more broken and brecciated than in the adjoining country to the east and west; that neither the calcite, the calcspar, the iron seams, the iron stains, nor the fracturing or fissuring is any more abundant within the limits of that lot, north of that point, than for a long distance to the eastward and westward; that wherever, in that belt, the surface of the rock is exposed by erosion or otherwise, there appear innumerable seams, cracks, small fractures or fissures, running in every conceivable direction, filled with calcite, stained more or less with iron, in instances containing some manganese; and that in many places the surface material is brecciated and re-cemented.

The evidence also shows that numerous samples were taken from the various open-cuts and exposures, but, with few exceptions, the assays of those samples taken north of the Silveropolis south end-line extended revealed either nothing or but a trace in any of the precious metals, and the few exceptions yielded little more than a trace—simply such results as may be obtained, at least according to the evidence of the plaintiff, in many portions of that limestone country where no vein exists, or beyond the limits of any vein.

(TO BE CONTINUED)

BISMUTH.—The marketed production of bismuth ore in the United States in 1904 was 5,184 pounds, valued at $314. No sales were reported in 1903 or 1902. A total of about 83 short tons of crude bismuth ore is reported as having been mined but not sold during 1904. The price of refined metal is kept so low by the combination controlling the business that profitable mining of our domestic ores is practically out of the question. Bismuth is valuable for the quality it gives its alloys with certain metals, by virtue of which they melt at low temperatures. The chief alloys are with lead, tin, and cadmium, singly or together, and in varying proportions according to the use to which the alloy is to be put. The melting point of the several alloys in common use ranges from 60° C. to 94.5° C., and they form safety fuses for electric apparatus, safety plugs for steam boilers and automatic fire extinguishers, some solders and dental amalgams, matrices for plaster or wax casts, etc. The bismuth alloys are used also for baths in certain operations which require liquids at definite temperatures below that of boiling water.—E. O. Hovey, in *Mineral Resources*.

THE *Engineering Record* gives an account of some magnetic observations which have been made by Thomas Russell, United States assistant engineer in the Tamarack copper mine, at a point 4,760 ft. below the ground, in a level about 1,200 ft. from the shaft. It was found that the diurnal range of declination in the mine, the difference between the morning eastern and the afternoon western elongation was 14 minutes of arc, which is about the same as observed at the surface of the earth at the same place. The times of elongation, or of maximum deflection, were about the same as at the surface. The total magnetic intensity in the mine was about one-fortieth part greater than at the surface of the ground, or 0.6227 of a dyne, as compared with 0.607. It was found that the dip decreased and the intensity increased as the observer descended farther into the earth. The work was done as part of the Great Lake survey.

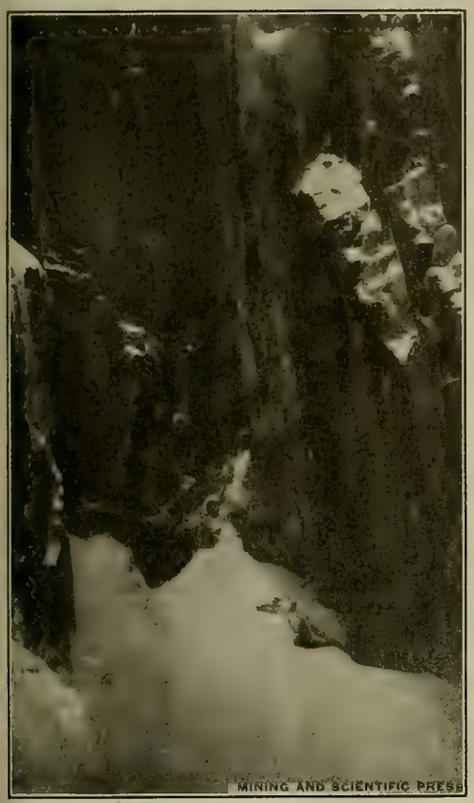
Cobalt.

Written for the MINING AND SCIENTIFIC PRESS by D'ARCY WEATHERBE.

This now celebrated mining camp is situated at an altitude of 925 ft. immediately west of Lake Temiscaming and 103 miles north of North bay, on the Canadian Pacific Railway, in Ontario, Canada.

The Temiscaming & North Ontario Railway (owned by the Ontario Government) which connects the mines with North bay, extends beyond Cobalt for some 50 miles; it is still in process of construction and it will eventually join the new trans-Canada Road near Lake Abitibi, and thus afford an entrance into that vast northland, so long the eager hope of the prospector and lumberman.

A handful of shacks grouped round a wide-eaved railway station comprised the Cobalt of June, 1905; January, 1906, saw over 100 buildings, two frame-and-shingle banks, a large stamped-metal boarding-house and the usual collection of pool-rooms, restaurants, barber shop and Chinese laundry, etc. The typical building of the townsite and mines is a log cabin, of varying size, built of round timber roughly hewed square on the inside and stogged with plaster or cement mortar—not with mud or moss, as is usually seen in the remote wooded country of Lower



Bluejay Vein at Surface.

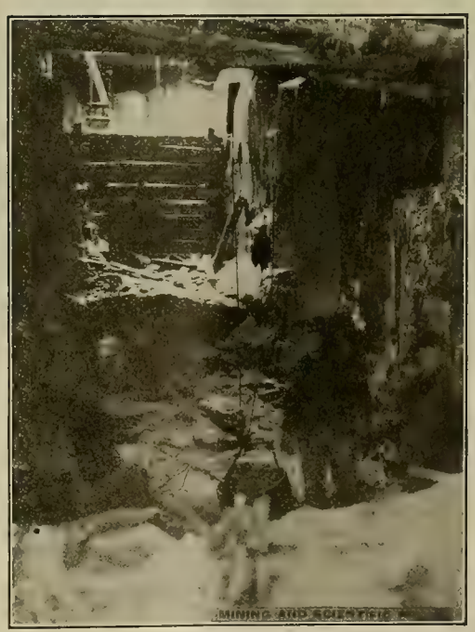
Canada. Besides these log cabins there are, interspersed throughout the settlement, shacks of every conceivable shape and structure, the board and tar-paper variety predominating.

I reached Cobalt in a storm of rain and sleet, after six hours in a '19-mile-an-hour' train, stuffy and crowded with a polyglot collection of humanity, speculators and business men from Toronto, miners seeking work, lumbermen with their snow-shoes, *habitants* of the district (Cobalt is only 20 miles from the Quebec border) reeking with *rouge* tobacco, and a few women and children. It was impossible to get a bed in the town, but fortunately I met an old college mate, R. W. Brigstocke, formerly connected with the Ymir mine, in British Columbia, and now manager of the Drummond mines at Cobalt, who made me most comfortable at his quarters; in fact, it is due to his kindness, combined with that shown me by R. J. Trethewey, N. A. Timmins and Capt. Harris, that I was enabled to see their mines under the most favorable circumstances.

I had little opportunity, however, of examining the surface conditions, as three feet of snow lay on the ground, and the country, which is undulating, is covered with a thick growth of hacmatack and spruce and both in topography and flora greatly resembles Nova Scotia.

The excellent reports of Mr. W. G. Miller, published by the Ontario Bureau of Mines, give a very full account of the geology of the district and tell of the development work on its immensely rich veins, up to June of the past year. Since that date, new discoveries have been added to the list, and instead of the six mines that were producing at that time, there are now 27 separate workings in operation in, and around, Cobalt—an area four miles long by two miles wide. True, some of these are only shallow pits on mere veinlets, but in this district where the ore runs to so much money per ton and in some cases is practically all native silver (valued at present at 66 cents per ounce), the fact will be appreciated that it does not take a large mine to produce a big fortune. I saw in the stock-shed at Timmins' La Rose mine 400 tons of ore in sacks, one bin of which was said to assay between $1,200 and $1,300 per ton. This mine has already produced, it is said, over half a million dollars from workings consisting of two shafts, the

La Rose Mine, Cobalt, Ontario.



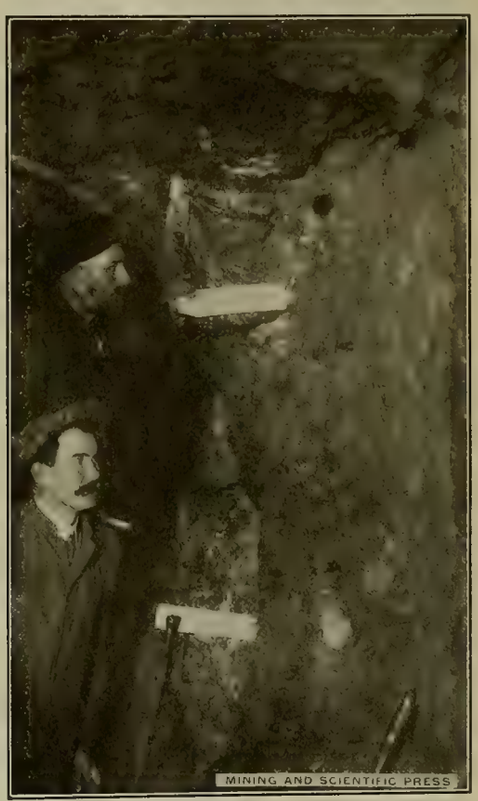
Cinderella Workings, Drummond Mine.

deepest of which is only 135 ft., a level (at 100 ft.) less than 450 ft. long and a winze 70 ft. below this level. (See Figure 1.) These are not extensive workings to make such a production, particularly when it is considered that the ore taken therefrom averages probably less than 12 in. thick and that not an ounce of it has as yet been stoped. Moreover these are the most extensive workings in the district, no other mine having yet reached a depth of over 70 ft. From the whole district more than $2,000,000 worth of ore has been produced to date, that is since October, 1903. La Rose Company has opened several other veins on the surface and from one has shipped three carloads of ore. The plant consists of two small boilers, a steam hoist and a four-drill Rand compressor supplying two machine-drills in the mine.

The extraordinary variety of metals and minerals in these ores, as explained fully in Mr. Miller's last report, is amply illustrated in a cabinet collection in the office of La Rose Company. There, the delicate pinks and greens of the cobalt and nickel blooms contrasting with specimens of native and ruby silver and relieved by the duller hues of the pyrite and pyrrhotite, bismuth, antimony, galena, with the sulphides and arsenides of the rarer metals, form as attractive a collection as could well be got together and will make a rich addition to the display in the Ontario Bureau of Mines.

On the day following my arrival the thermometer dropped to 12° below zero and a biting wind made it most disagreeable. My available time was short and although I had a cursory view of almost all the workings in the district I was only really able to examine, beside La Rose mine, the operations of the Drummond Mining Company and part of the workings at Tretheweys; these are the three most important mines. I was pleased to see that a Nova Scotia syndicate had struck it rich at one point. The manager is Mr. Woodworth, recently of the Big Five Company, at Renfrew.

The Drummond Company is working at two points on the east side of Kerrs Lake and close to the shore (Fig. 2 and 3). The methods of opening and extracting the ore—it can hardly be called 'mining' yet—



La Rose Vein. (See A, Fig. 1.)

generally employed in the district are exemplified here (see Fig. 2 and 3 and photograph). The vein is stripped for a short distance along the outcrop, and trenched for about 20 ft. deep. A shaft is then sunk, either at one end or in the middle of the trench, and the opening is lagged over with heavy poles while a sort of open stoping operation (underhand method) is carried on pending the sinking of the shaft to a depth necessary for a regular drift. The hoisting is being done by horsewhip and derrick, as is also the unwatering; but a boiler, hoist and small compressor have been ordered. A diamond drill has commenced boring on the property to prove the veins in depth.

In the Cinderella workings, three veins, aggregating about nine inches of ore, are being mined, and at the Bluejay pit, a vein (Fig. 4, and the photograph), which at the surface measured about eight inches, split up into several bands consisting chiefly of calcite and cobalt bloom; at a depth of 20 ft. it is giving good percentages in native silver and smaltite, but is reduced in size to between two and three inches. The ore when hoisted is all picked over in the cobbing shed by two men; at present it is divided into three grades: No. 1, chiefly composed of cobalt and silver; No. 2, calcite and silver; and No. 3*, a lower grade ore, which is at present left on the dump. No. 1 and 2 are said to comprise over half the ore mined. The shipping ore is placed in sacks measuring 15 in. by 21 in. and weighing 110 lb. when full. Much care has to be taken in packing and

*It has been stated that under the prevailing freight rates and prices paid for ore in New York, it does not pay to ship any material assaying under $50 to $60 per ton.

shipping on account of the great value of small lots, and when I was in Cobalt two ore-thieves were in limbo, at the neighboring town of Haileybury, awaiting trial. A great nuisance to the managers of the mines is the importunity of visitors who ask for souvenirs—which in this district practically means begging for *money;* indeed, at one of the chief mines situated close to the railway the owner informed me that during the past summer over $1,000 had been carried off in this manner. The consequence is that at the larger workings strict rules are in force prohibiting any one from access to the mines or buildings without a special permit from the company's office.

At the Trethewey mine, a short distance west of the railway and near the townsite, a number of veins have been opened, but their average width is not over 2½ in.; three or four of these have been opened by trenches to a depth of about 20 ft. and two shafts, each about 70 ft. deep, are in process of sinking, a small compressor, hoisting plant and air-drills being employed in these operations.

At the Coniagas* property, controlled by Trethewey and others, the open-cut on No. 3 vein represents the curious sinuosity in strike mentioned at one place in Mr. Willet G. Miller's report, and partly accounted for by the vein dividing around a columnar structure in the country rock; the dip of the vein, as is usually the case throughout the district, is about vertical. Some of the ore now being mined on this property contains $3,000 per ton in silver. Three lumps of ore, almost entirely native silver, in the Imperial Bank at Cobalt, weighed 270 lb., 236 lb. and 30 lb., respectively.

All of the veins so far discovered, with the exception of a few in the diabase and one or two supposed to be in the underlying Keewatin rocks, occur in the measures assigned to the Lower Huronian. By reason of the great age, metamorphism and shattering, the stratification or bedding of these rocks is not readily apparent, but it is evident that they generally lie at a comparatively flat angle and the veins, which cut them vertically, have, as a rule, a smooth wall on each side. One of these walls is generally utilized when breaking the ore in the mine.

The supply of labor is at present in excess of the demand, but it is largely composed of men who are simply congregated here to accustom themselves to the conditions, so as to be prepared for prospecting immediately the snow leaves the ground. It is expected that spring will advent the greatest rush that has ever been experienced in Ontario, and much anxiety is felt as to the intentions of the Government in the matter of modifying the existing mining laws and throwing open for prospecting the timber limits lying immediately south of the camp.

Labor is paid prices approximately the same as in British Columbia; the rates at most of the mines are as follows: Surface labor, $1.50 to $1.75; miners, $1.75 to $2; helpers, $2 to $2.25; drill men, $2.25 to $2.50. In each case, board and lodging, equal to about $5 per week, is paid as well. Undue excitement and a boom atmosphere prevails at Cobalt, and fabulous prices are asked for merely superficial exposures of ore. Town lots, too, are selling at unreasonably high figures. One 20-ft. front (of stumps), situated on a rough side-hill, was reported as selling at $400 the day I left. Doubtless, such conditions are the inevitable accompaniment of bonanza discoveries and one pleasurable feature that I observed was the universal caution so far exercised in regard to expenditures in plant, equipment, etc., at the mines. Companies with heavy capitalization, and in some cases, I fear, with doubtful assets, are being floated with more frequency each week.

Up to the present time, I believe that no vein has been found to extend from the Lower Huronian rocks (in which they generally occur) into the underlying Keewatin, which, according to Mr. Miller, do not afford the same favorable conditions as the former. The *extreme* known thickness of the Huronian in this district is given at 500 ft., but this only occurs in spots, great erosion having denuded all but the ancient hilltops. The one or two veins, said to occur in the Keewatin, are not excessively rich, and they may have been of earlier origin than the Huronian veins. At any rate, they and the few veins occurring in the diabase, are not characteristic of the producing ore deposits of the district and need hardly be taken into account when considering upon the general question of persistence. Only one vein has been traced for as much as 1,000 ft. along the surface and it is extremely doubtful whether this was rich at more than a few spots, if indeed at more than one. All the worked veins in the district, I am told, do not average six inches in thickness and many of them have been proved to become smaller in depth.

Bluejay Vein at Surface.

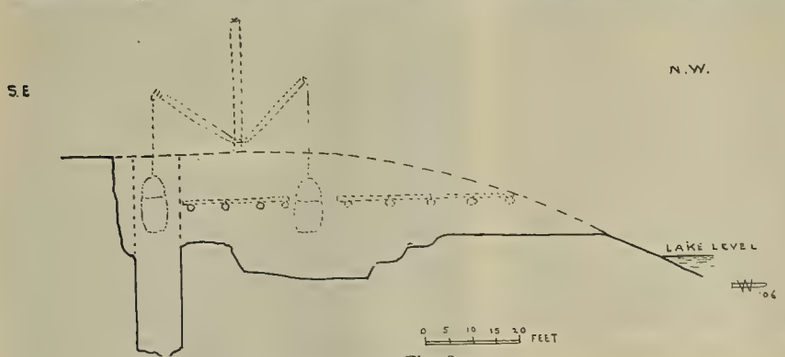

Fig. 2.
Longitudinal Section, Drummond Mine.

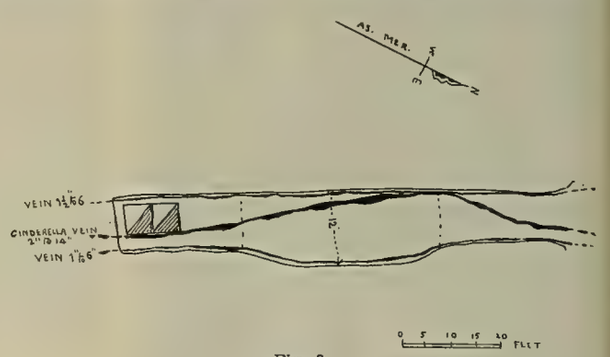

Fig. 3.
Plan, Drummond Mine.

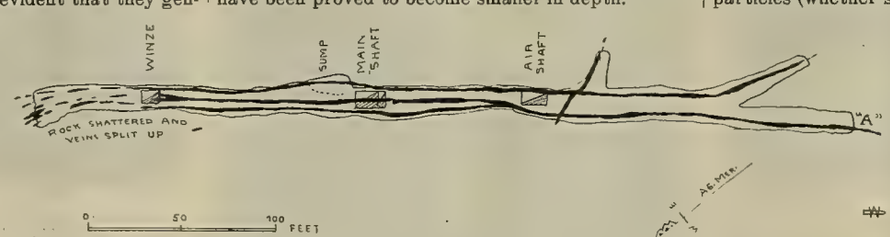

Fig. 1.
Sketch of 100-ft. Level, La Rose Mine.

In the light of these facts, reckless expenditures and high-financing methods incidental to a boom should be discouraged, at least until more has been learned of the practical character of the deposits by drilling and mining. No doubt much money will yet be taken from the veins now being worked and those probable veins yet to be discovered, but development work so far can hardly be said to point to future mines which, though probably containing extremely rich ore, approach the unlimited in depth and extent

The smelting companies to which the ore has been shipped, are now only paying for 90% of the silver, nothing being allowed for the nickel, cobalt, and, particularly, for the arsenic. Recently parcels of ore from Cobalt that had been shipped to the Eastern States for treatment were re-shipped to Canada to the International Nickel Company's modern smelter at Sudbury. Experiments there have proved successful in eliminating and collecting the arsenic and in producing a matte of the other metals which can be refined. These facts were given me by the general manager of the smelting works. The practical suggestion of Mr. Miller, of erecting an arsenic reduction plant at some point between Cobalt and the Temagami district, which contains the high percentage mispickel ores, is well enough, but whether it is a good idea to add to this a smelter and refinery, as has also been suggested, for the treatment of the metals in the Cobalt ores is doubtful at present, as the process is said to be expensive and extremely difficult, and requires much careful experimenting to perfect. About 200 miles of freight charge, at least, would be saved by such a plant, however, and with the application of available water-power the treatment charges could be reduced to a minimum.

*So called from the fact that each successive pair of the letters in the name is the chemical symbol of some metal in the ore.

Lime in the Cyanide Process.

In the cyanide process lime has two principal functions: one chemical, in neutralizing acid; the other mainly physical, in coagulating slime and hastening the settling of fine particles. In slaking, the calcium oxide (CaO) takes up water to form the hydroxide $(CaOH)_2$, which dissolves in water to the extent of about one part in 800. This solution neutralizes sulphuric acid, and decomposes ferric sulphate contained in the ore or tailing, or developed in them by oxidation during treatment, and also combined with carbonic acid derived from the atmosphere, thus protecting the potassium cyanide. In this respect it is preferable to caustic soda, as the carbonate of calcium is insoluble in water, and the sulphate but slightly soluble, so that they do not accumulate in the solution, as the corresponding sodium salts would do if NaOH were used as a neutralizing agent. Soluble carbonates are also precipitated by it, leaving caustic alkali in solution, thus:

$$CO_2 + Ca(OH)_2 = CaCO_3 + H_2O$$
$$Na_2CO_3 + Ca(OH)_2 = CaCO_3 + 2NaOH.$$

Its effect in settling slime is of a more complex character. Much of the material properly classed as slime is of a 'colloid' nature, and when brought in contact with pure water becomes almost gelatinous and impermeable to solution. Certain substances added to the water, notably alum, lime, acids and soap, coagulate or flocculate this gelatinous material and cause it to separate into more or less distinct particles or agglomerations. Again, excessively fine particles (whether slimy or not) if suspended in water and settling very slowly, have their rate of settling much increased by the addition of lime, acids, alum or other salts. The causes of these phenomena are as yet imperfectly understood, but they are of great importance in hydrometallurgy and in agriculture. Although, weight for weight, lime is less efficient in coagulating and settling than either alum or sulphuric acid, it is generally employed both for slime and for soil, because of its additional advantage in neutralizing acids. The question of settling has been studied by Barus, United States Geological survey, *Bulletin* 36, and by several others whose work is summarized by Julian & Smart, 'Cyaniding Gold and Silver Ores,' page 204, *et sequitur.*

A WATER-PROOF CEMENT has just been patented in Germany. A mixture of vegetable wax and caustic lime in boiling water is added to unground portland cement clinker, and all ground together. The inventor makes the claim that one-half inch coating of this cement placed on a brick wall will render it absolutely water-proof. The formula is given as follows: To each two hundredweight of cement clinker is added a mixture of three-fourths of a pound of Japan vegetable or berry wax, and one ounce of caustic lime which has been dissolved in 14 pints of boiling water. These ingredients are thoroughly mixed, and when cooled are dried and ground very fine with cement clinker.

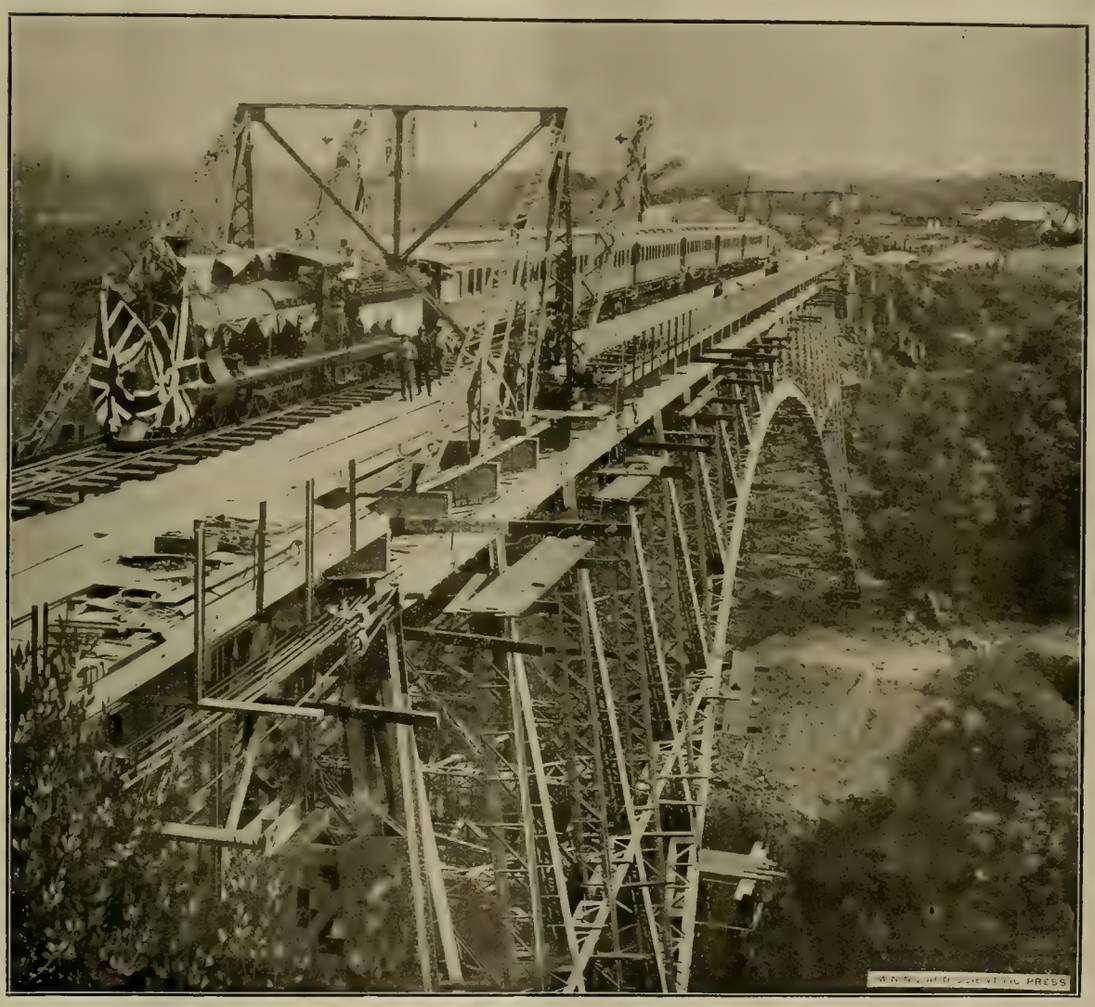
THE coal production in the principal coal-producing countries of the world was in 1904, the latest available year, as follows: United States, 314,563,000 tons; the United Kingdom, 232,428,000 tons; Germany, 118,907,000 tons; France, 33,303,000 tons; Belgium, 23,135,000 tons, and Japan, 9,701,682 tons, the quantities in each case being long tons of 2,240 lb. each.

Victoria Falls Bridge.

Specially contributed to the MINING AND SCIENTIFIC PRESS.

Writing about the Rhodesia railways in 1900, to Mr. Ewart S. Grogan—a traveler who had just completed an adventurous journey from the Cape to Cairo—Cecil Rhodes said: "We propose to go on and cross the Zambesi just below the Victoria Falls. I should like to have the spray of the water over the carriages." Were Cecil Rhodes alive now he would see his dream realized, for the railway from the south has been carried from Bulawayo, through the valuable coalfields at Wankie, right up to those wonderful falls, which are twice the height of Niagara and more than double its width, and, simultaneously with the construction of the Victoria Falls bridge, has been pushed forward till the railhead is now 260 miles north of the Zambesi.

The bridge has been constructed at a spot where the gorge is 650 ft. across at the upper level, and the depth from the top to the surface of the water below, in the dry season, is nearly 400 ft. The sides of the chasm are formed of an igneous rock, hard in structure, reddish brown in appearance, and well covered with vegetation. Prior to the construction of the bridge this rock had always been thought solid, but when the work of excavating the foundations for the abutments of the main arch was undertaken, it was discovered that the upper part of the south bank was composed of rock debris to a considerable depth. This unexpected circumstance not only caused much unforeseen labor and loss of time, but it necessitated the lowering of the level of the entire bridge by 20 ft. It is probable that the place where this debris lay was formerly the precipice over which the water fell, previous to the time when the dividing barrier between it and the present fall was removed by the erosion of water. The bridge consists of a main span 500 ft. long, the arch of which it is composed being 15 ft. deep at the center and 105 ft. at the springing. The rise of the arch is 90 feet.



The Cantilever Bridge Across the Zambesi.

The contract for this great engineering work was finally secured by an English firm—the Cleveland Bridge & Engineering Company of Darlington—and although everything possible was done to assist the contractor, the erection of the bridge was a matter of much difficulty. He was provided with free transport to the spot for all material to be used, houses were built for the workmen, and a powerful aerial cableway was provided for the transport across the hitherto impassable gorge of one half of the material for the construction of the bridge, which was designed so that it might be built out from both sides simultaneously.

The cableway consisted of a steel wire rope of 8.4 in. circumference, with a breaking stress of 270 tons, and 830 ft. long, suspended between two supports, one of which was vertical and of ordinary type, the tension of the cable being carried by guy-ropes fastened in the rock. The other support was inclined and carried a weight of several tons, equal to the working stress on the cable. As the conveyor moved across the gorge to the center this weight was lifted, but fell again as the conveyor moved over to the far side. The effect of this 'compensating' arrangement was to make the power required for operating the conveyor more uniform throughout its travel. The conveyor, of the 'Brothers' type, carried its own driving mechanism, operated by a Crane motor of 20 b.h.p., and lifted a load of 10 tons at a speed of 20 ft. per min. and traveled with it at 300 ft. per min. The motor received current from a trolley wire crossing the gorge, the electric supply being obtained from a small generating plant sent out for this purpose. This plant consisted of a dynamo, running at 970 rev. per min., and generating 220 volts, driven by a portable engine of 14 nominal horsepower.

The conveyor successfully handled all the material required for the northern half of the bridge, and many thousands of tons of permanent-way material required for the construction of the portion of the line north of the Zambesi. Some time before the completion of the bridge, the main cable and the conveyor showed signs of wear. As the plant was of such vital importance, both a spare cable and conveyor were constructed, but, as a matter of fact, the original plant held until the bridge was sufficiently completed to permit of a contractor's road for carrying railway material being laid across it.

Owing to the immense depth of the chasm, the bridge was designed so that, throughout the process of its erection, commencing from opposite sides, each half is a cantilever until their ends, reaching one toward the other, join in mid-air, when it becomes an arch. This type of design made an efficient anchorage during erection a necessity. The strength of the attachment had, therefore, to be equal to the pull caused by the weight of the projecting bracket or cantilever, with a sufficient surplus for safety. The pull on the anchorage apparatus was estimated at 400 tons, and in the present case the means of attachment were provided by a series of steel wire ropes. These were secured to the top of each cantilever, and carried to a point some distance to the rear, where they entered a hole bored downward in the solid rock, through it at right angles to the bridge, and up again on the other side; thus each wire formed a loop gripping the rock, with its free ends fixed to the cantilevers.

The most difficult part of the construction of the bridge was the erection of the end spans, but when once the tall end-posts of the main span were erected, and the short spans were connected with them and the shore, affording a stable platform to start from, the work proceeded rapidly and smoothly.

The designing of the bridge was the work of many months in the office of the company's engineers, Sir Douglas Fox and Sir Charles Metcalfe, the calculations being long and laborious. The quality of the steel of which the structure was composed was strictly defined in the specifications, and the material itself, which was rigidly inspected and tested, is capable of bearing an ultimate tensile strain of 30 tons per sq. in. As regards quality and accuracy of workmanship, it was stipulated that the principal members should be made to within one thirty-second of an inch of their calculated length. Before being shipped, every panel of the arch and lateral bracing was put together in the contractor's works, and fitted with perfect accuracy.

Owing to the spray from the falls which descends upon the bridge during the wet season, the question of maintenance is of paramount importance, and it is an important feature of the design that every portion of the steelwork is accessible to the painter's brush. The painting can, fortunately, be succcessfully carried out by natives. This is particularly satisfactory, as, prior to the advent of the railway, there was not a native living within 60 miles of the falls, owing to their superstitious dread of the locality, but now that this has been overcome the proper preservation of the structure is assured.

A special and most suggestive feature of transportation by steam, electricity and other kinds of mechanical force is that its capacity is not only unmeasured and unknown, but will doubtless prove to be practically inexhaustible. That is to say, no certain limits can be assigned to the operation or effect of these new agencies as compared with those which have been superseded. Therefore, speed may reach many times the rate now attained, the size of vehicles may be greatly increased and the cost of carriage for the longest distances reduced to an astonishing minimum; so that as progress goes on in developing the means and methods of distribution, the habits and needs of men will be more and more modified, with consequences to social order and the general conditions of life which may be far greater than have yet been imagined.

But this is not all. Another fact is still more wonderful. Coincident with this sudden transfer from animal power to steam have come the new and amazing means of transmitting intelligence. In a brief generation the barriers of time and distance, hitherto so formidable, have been swept away by telegraph and telephone. No longer limited to the agencies by which material things are transported, we send our thought and speech with lightning swiftness to the four quarters of the globe, and hold all lands and peoples within the sphere of instant intercourse. So recent is this miracle that we are dazzled by its marvels without realizing its tremendous import.

That this substitution of steam and electricity as the instruments of commerce and communication has been an immeasurable gain is witnessed here and everywhere by half a century of unparalleled progress. Along these wondrous pathways the world has literally leaped. Released from dependence on beasts of burden, the entire realm of industry has been quickened and enlarged; productive energy has been vivified by new and limitless means of distribution; the products of the whole earth are embraced in wide circles of exchange; all the luxuries of all lands are brought to every household; wealth has multiplied until we are almost surfeited with its abundance, when other people possess it; the genius of invention has been stimulated to larger exercise, the sphere of thought grandly extended, the impulses of charity awakened to nobler activity, while keener sympathy through closer contact is pointing the road to real brotherhood.—Martin A. Knapp in *Science*.

STEAM SHOVELS are now being used for stripping copper deposits, in a manner resembling the practice of the iron mines of Minnesota and Michigan.

The First Writer Upon Mines.

Written for the MINING AND SCIENTIFIC PRESS by a Special Contributor.

"There was a man in the land of Uz, whose name was Job." Thus in a few simple words we are introduced to the earliest known writer upon mines. Unnumbered centuries before Lyell wrote, and the science of geology sprang into being, Job recognized the paramount agency of volcanic disturbance in the upheaval of the geological formations in mountain building. Thousands of years before Dana and Judd and Dutton had studied volcanoes; before Powell and Gilbert of the United States Geological Survey made known the Basin Range structure and traced the evolution of the mountain ranges in the great volcanic region of the West, Job described a similar desert region in the Far East and the evolution of its topography. "As for the earth, out of it cometh bread; and under it is turned up as it were fire. The stones of it are the place of sapphires; and it hath dust of gold. He putteth forth his hand upon the rock; he overturneth the mountains by the roots. He cutteth out rivers among the rocks."

Although from the dawn of history, sapphires were found in gravel deposits, associated with other precious stones, nothing was supposed to be known of the geological formation from which they were derived, until Weed published the finding of sapphire in the igneous dikes of Yogo gulch, Montana. For no one appears to have understood the meaning of the passage, where Job, describing the evidence of igneous upheaval in the earth's crust, recites, "The stones of it are the place of sapphires; and it hath dust of gold."

In the early part of the last century, Humboldt was impressed with the association of igneous rocks with ore deposits; a theory treated in the most convincing way, in our own day, in that classic paper of Kemp, 'The Role of the Igneous Rocks in the Formation of Veins.' The genetic relation of volcanic phenomena with the occurrence of mineral formations, seems to have impressed Job as it did Baron von Humboldt. The evident belief of the writer of Job, that minerals were formed through fissures coming from the unknown depth of the earth's crust, is the accepted theory of our leading specialists upon ore deposits. "There is a path which no fowl knoweth, and which the vulture's eye hath not seen; the lion's whelps have not trodden it, nor the fierce lion passed by it."

Special mention is made of the occurrence of silver and gold in veins; while iron ore was mined from deposits in the earth, and brass (which also included bronze), was smelted from a mixture of the ores of copper and tin, and of copper and zinc. "Surely there is a vein for the silver, and a place for gold where they fine it. Iron is taken out of the earth, and brass is molten out of the stone."

The opening verses quoted, of the 28th chapter of the book of Job, appear to be only a fragment; it is thought that a portion of the poem is lost—a view supported by the repeated interruption of subject. Possibly no passage in the Bible has been more often misquoted, or is less understood than the opening verse; "Surely there is a vein for the silver, and a place for gold where they fine it." Gold-quartz veins are known to have been worked, at a time so remote that all record is lost, in parts of Africa tributary to the commerce of the people of the East. It is probable that river gravels were washed for gold at a still earlier period. At first, the rock was broken by stone hammers, and at a later date, metal tools were used. Fires were built against the rock-face, and when the quartz was hot, it was shattered by throwing water upon it. The ore was crushed by large stones, and the gold obtained by winnowing the dry pulp with mats, in a manner similar to that employed in working dry placers. Where water was available, it is probable that the crushed ore was washed over matting to catch the gold, in the way now practiced in Japan. The numerous excavations, and the remains of stone mills used in grinding the ore, in the ancient gold-quartz mines of Zanzibar (by whom, or when worked, nothing is known), show that even before the historic period, the arts of mining and treating ore were well advanced. Beyond the sphere of influence of modern civilization, the East changes little its ways of doing things in the lapse of ages, and it is probable that the primitive methods of extracting and refining the metals, in use in remote regions at the present day, closely resemble those employed in the time of Job.

Gold obtained from dry placers or from river gravels, was of a fineness suitable for immediate manufacture into ornaments, the "jewels of fine gold," but much of the gold of the veins was combined with silver and had to be first refined. The refining of the vein-gold was a long and tedious process, requiring so much fuel that it was usually carried out at the mines, in mountainous districts where wood could be readily obtained. Fuel was possibly as scarce in the grazing country in which Job lived, as it is on the plains of the West. As practiced in remote parts of the East, gold alloyed with silver is refined for the manufacture of jewelry, by native goldsmiths, who use a process of cementation with salt that is probably of very ancient origin. The gold is melted and cast in thin discs, which are packed on edge in a furnace, imbedded in a mixture of wood ashes and crude salt, and subjected to prolonged heating at a temperature such that the silver is gradually converted into chloride, without melting the gold. The discs are removed from the furnace, and while hot are thrown into a strong solution of salt to dissolve the silver chloride formed. After cleaning by scouring with ashes, the discs are melted, re-cast in discs, and charged as before in the furnace. The process is repeated until the gold is of the desired fineness. The salt used, obtained from the natural salt lakes of the country, is often mixed with sodium sulphate, which in the cementation aids the chloridizing of the silver by decomposing the sodium chloride. The term, 'fining the gold,' seems to have been sometimes applied to the whole process of extraction of the gold from the ore and the subsequent removal of the silver. The refining of silver and also of gold (alloyed with copper and other base metals), by cupellation with lead, upon a hearth of leached wood-ashes or bone-ash, is supposed to have been first practiced in the mines of Greece and the Mediterranean provinces. Whether the process of refining by cupellation, was known in the time of Job, the fragment preserved of the 28th chapter gives no information. It is probable, however, that the knowledge of fusion methods of refining, came from the West, with the knowledge of mining for the ores of silver and lead.

Job closes with these words: "But where shall wisdom be found? and where is the place of understanding?" "Man knoweth not the price thereof; neither is it found in the land of the living."

Concentration.

The object of concentration is to separate or 'concentrate' the rich particles containing the valuable metals from the great mass of sand, in which they are disseminated, and which may be either the tailing from a mill where they have already been subjected to various processes, or may be the direct product of grinding low-grade ores. In general, it may be said that the 'concentrate' constitutes the particles saved coarser than 100-mesh; the 'fine' that between 100 and 500-mesh, and settling in water quickly, while 'slime' is in a still more minute state of division and is held in suspension by the water, or floats on top, settling only after long standing. Slime is collected only by adhesion, or cohesion, as the mineral in this state flows off readily in a stream of water, and refuses to settle away from the accompanying gangue. If dry points occur, the water, as a consequence, runs in streaks, and at the junction of the wet and dry channels minerals will be picked up and floated away on the surface of the water; this 'floating' of the mineral is caused by its dryness, not by its lightness—it has been coated with a film of air. 'Middling' is a term used to describe particles of gangue firmly united with minute particles of ore; it is a product generally obtained in the process of concentration. It is common practice to return this product to the head of the table; but as the ultimate object to be attained by concentration is the separation of the mineral from the gangue, the procedure is useless, for the second effort of concentration simply repeats the first process, and will be of no avail unless it includes re-crushing, to liberate the metallic mineral.

The tendency of a mixture of ore particles of approximately similar size, but of varying specific gravity, is to arrange themselves when in motion in layers according to their gravity. Another important feature on which concentration is based is that thorough settling sends the heavy metallic minerals to the bottom, leaving the lighter on top, any other material too low in grade to pay for further treatment being run to waste. The concentrate—if rich enough—is shipped without further handling; but it is found occasionally economical to re-concentrate it over another table, running at slower speed and increased grade; in this case two machines of the same type are used, the concentrate from the first passing directly to the second. With some ores it is advisable to re-concentrate the tailing from the first operation in order to further save that portion of the slime which may contain sufficient value to warrant this additional treatment.

As a working guide, it may be stated that an ore to be considered capable of concentration must have a gangue which mills freely, so that the fragments of the concentrate may be freed from the gangue without being reduced to slime. That is to say, the gangue should either break readily or be softer than the enclosed metallic minerals. It is also essential that the valuable minerals be fairly hard and of a distinctly heavier specific gravity than the gangue, as otherwise not only will they be reduced to slime in the process of milling, but it will be impossible to separate them afterward. Lead carbonate and the carbonates and silicates of copper may, therefore, be classed among those ores which are to be excluded from treatment by concentration.

The earliest and simplest form of concentrator is the miner's pan. The shaking action given by the operator tends to settle the heavy grains to the bottom, while the light and worthless particles are washed away by the water. Broadly speaking, we may divide the methods of wet concentration under six heads:

1. Concentration by a large and nearly horizontal stream of rapid running water, where, the whole mass being in free motion, the heavier particles sink to the bottom and are caught by 'riffles,' and the lighter are washed away. This is the sluice-box of the hydraulic miner.

2. By a thin skin of comparatively slowly moving water mixed with fine material only. Under this head may be classed 'undercurrents,' blankets, canvas tables, etc.

3. The same as No. 2, but with the addition of action in some form, to assist in settling the heavier particles.

4. The same as No. 2 and 3, but with the motion arranged in such a way as to cause the heavy particles not only to settle to the bottom, but to travel continually in one direction, so as to assist in the separation of the sand and the heavy mineral. Generally speaking, the motion of the particles is at right angles to the direction of the current of water. (Table concentration.)

5. In which the motion is arranged so as to merely cause settling, the current of water removing the sand. This, in conjunction with a moving belt, forms the well-known belt concentrator, or Frue vanner.

6. In which opposing currents of water in a tank are utilized in a combination with gravity to classify the particles and make a separation. These are known as hydraulic classifiers, and their operation depends on what is known as "the law of equally falling bodies," which may be stated as follows: "Bodies falling free in a fluid fall at a speed proportionate to their weight divided by their resistance." From this it will be seen that small masses of a heavy mineral will fall as rapidly as large masses of a light mineral, owing to the fact that the weight increases as the volume, and the resistance only as the area. These hydraulic classifiers are generally used to size the pulp of a mill before passing it to the concentrators, and especially to separate the very fine slime.—*Bulletin*, the Joshua Hendy Machine Works.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

The rocks from Oasis, Nev., are: No. 3, andesite; No. 4, diabase.

The rocks from Orseco, Or., are: No. 1, felsite, containing pyrite; No. 2, diorite.

The white mineral specimen from Dayton, Nev., marked S. G. T., is gypsum; variety, satin spar.

The two mineral specimens from San Jose, Cal., are: No. 1, a slaty gouge; No. 2, crystalline limestone, containing iron sulphide.

The sample from Breckenridge, Colo., marked T. A. B.: No. 1 is aplite (a micaless granite occurring in dikes and intrusive masses).

The rock sample from Dyer, Nev., is metamorphic. Some of it is greenstone schist, and some pieces consist almost wholly of granular quartz, others largely of iron. The bright, shining mineral, resembling galena is micaceous iron ore (hematite).

The rock samples from Badger Hill, Cal., are: No. 1, a dike rock, somewhat altered. It contains a little pyrite. No. 2 is a feldsitic dike rock. The sulphide is marcasite (white iron sulphide). No. 3 is a much-decomposed, igneous rock of granitic type.

The rocks from Atwater, Cal., are: No. 1, greenstone schist, with red iron oxide, green copper carbonate, and a little quartz; No. 2, quartz, with mispickel (arsenical iron sulphide); No. 3, quartz and iron oxide, with iron-stained clay. No. 2 may be gold bearing.

The rocks from Nevada City, Cal., marked J. R., are: No. 1, felsite, containing finely disseminated pyrite. No. 2 is a silicious dike rock. No. 3, diorite; No. 4 is evidently an altered dike rock, in which occur quartz and pyrite. This last rock may be gold bearing and should be assayed.

The rock samples from Homestead, Or., are: No. 1, a metamorphic, silicious rock, containing green epidote. No. 2, a much altered, granitic rock, apparently from the vicinity of a vein. This rock may contain gold. No. 3, calcite (calcium carbonate). No. 4, a fine-grained dike rock (diorite ?), containing a little chalcopyrite. No. 5, similar to No. 4, but rather coarser grained. No. 6, diorite.

Mining and Metallurgical Patents.

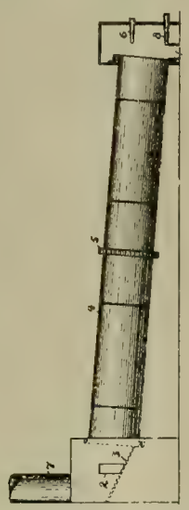
PATENTS ISSUED FEBRUARY 20, 1906.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

AGITATOR FOR CYANID SOLUTIONS.—No. 812,460; H. P. Smith and F. J. Hobson, Guanajuato, Mexico.

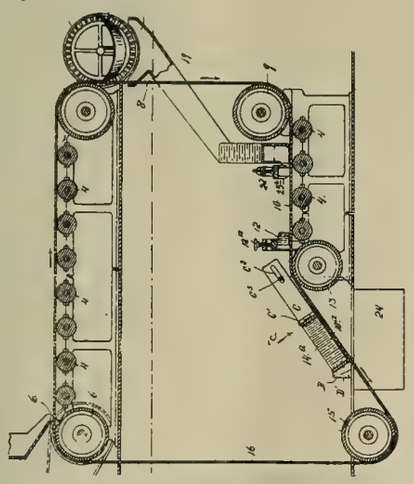
In apparatus for treatment of ores, tank and shaft rotating therein, stirrer-arms operated by shaft, pipes carried by stirrer-arms, and means for supplying pipes with compressed air; such means permitting removal of pipes from solution in tank at desired times.

PROCESS OF TREATING ORES.—No. 812,473; E. W. Arnold, San Francisco, California.



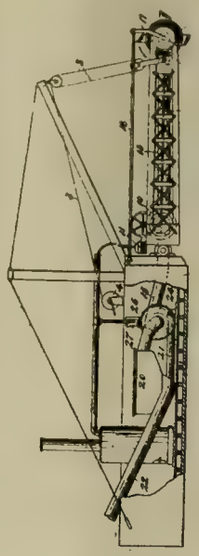
Treatment of refractory ores which comprehends heating of ore to incandescence, and direction of blast of chlorin gas and charcoal-fumes upon and into body of ore, while latter is in state of incandescence.

ORE-SORTING BELT.—No. 812,270; F. W. Jacques, Victor, Colorado.



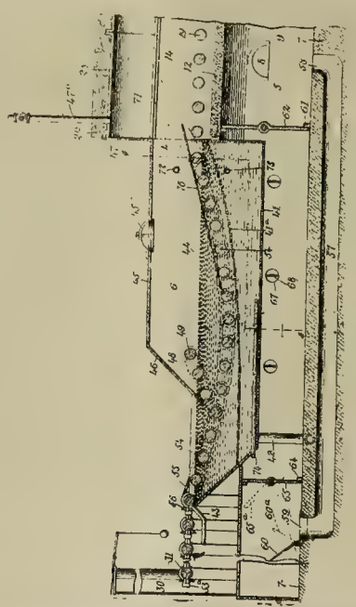
In ore-belt apparatus, combination of endless traveling belt or apron one part of which is considerably higher than other, means for delivering ore to be treated, to upper portion of belt, rotary grizzly for receiving discharge from upper portion of belt, chute for receiving finer material which passes through grizzly between its extremities, and arranged to discharge material upon lower portion of belt, vertically adjustable spreader located adjacent point of discharge and extending transversely of belt, and discharge device mounted above belt remote from spreader and consisting of stationary inclined wings located to scrape material from belt and discharge same on opposite sides thereof, arm pivotally connected with apex or angle of inclined wings and adapted to be swung in either direction for purpose of discharging whole of material on either side of belt, and small V-shaped device located above central portion of belt and directly in front of pivoted arm when in its central position whereby material upon belt is prevented from interfering with action of arm.

DREDGER.—No. 813,252; V. A. Strom, Alameda, California.



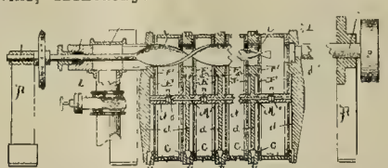
In dredger, float, hinged ladder projecting therefrom, with means for raising and lowering its front end, an excavator carried upon front of ladder, an internal receiver into which excavator discharges, receiver having closed bottom and open top, means whereby receiver may be turned axially relative to ladder to maintain its open portion uppermost during raising or lowering of ladder, and a suction pipe connecting with receiver.

PROCESS OF TREATING METALS.—No. 813,206; H. H. Goodsell, Indiana Harbor, Indiana.



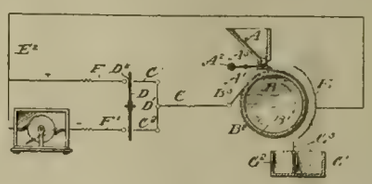
The method herein described of treating plates of metal, which consists in subjecting the same to action of aeriform body, of which different portions are heated unequally, plates being first brought into contact with portions of aeriform body having comparatively low temperatures and passed successively along to portions having higher and higher temperatures, and finally causing plates to emerge into open air.

FILTER-PRESS.—No. 813,121; S. Thurstensen, Louisville, Kentucky.



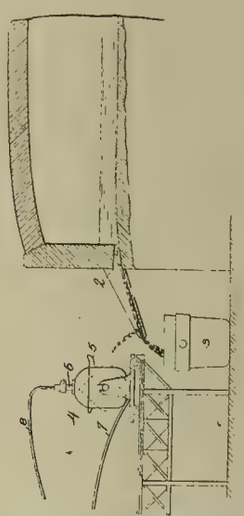
In filter-press, series of separated filter-plates having near their tops alining apertures adapted to have material distributed therethrough, rotatable worm-feed passing transversely through all of alining apertures, filter surfaces of filter-plates being provided with plurality of closely adjoining ribs forming deep narrow channels, filter-screen for each of filtering surfaces, drains on each of plates communicating with channels therein and adapted to receive and discharge liquid therefrom, means for rotating worm-feed to clear apertures and distribute material, alining hubs for each of filter-plates outwardly extending to contact inner face of filtering screen, abutments outwardly extending from hubs and adapted to clamp filtering screen between hubs and abutments, and bolt for each of filter-plates passing through hub and clamping abutments, hubs and abutments extending continuously from end to end of filter and adapted to distribute pressure on intermediate filter-plates to end plates.

PROCESS OF SEPARATING SUBSTANCES OF DIFFERENT DIELECTRIC CAPACITIES.—No. 813,063; H. M. Sutton, W. L. Steele and E. G. Steele, Dallas, Texas.



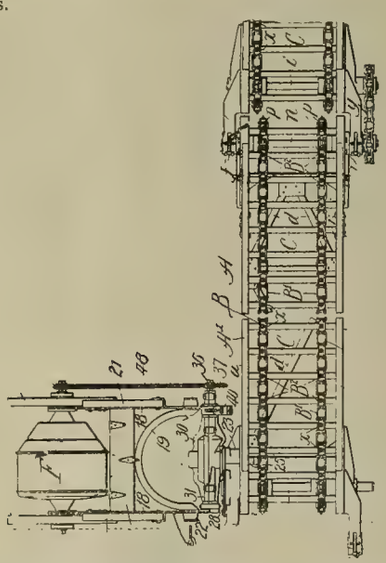
In process of separating particles of mass or components of a mixture, developing in particles or components dielectric hysteretic impedance, and separately collecting the particles.

PROCESS OF COMBINING TITANIUM WITH OTHER METALS.—No. 813,278; F. E. Canda, New York, New York.



Process of combining titanium with other metals, which consists in melting separately titanium-bearing material and the metal to which the same is to be added, and then uniting the two molten substances.

CONVEYER.—No. 813,134; C. H. Anderson, Chicago, Illinois.



In conveyer, conveyer frame having sides each constructed with mutually braced parallel upper and lower channel bars forming guides, shafts journaled toward opposite ends of the frame, sprockets on shafts, endless parallel conveyer chains, extending around sprockets, formed of alternate heads and links pivotally connected together, an endless series of transverse tubes connected toward opposite ends with heads of respective chains, shafts passing through and journaled in tubes and movable at their ends in guides, and driving means for the chains.

Mining Summary.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

Special Correspondence.

LONDON, February 21.

The old order changeth slowly in the ancient seabound strip of country west of the Saltash bridge. In the days of yore when the Limited Liability Act of 1862 was still unborn, mining as conducted in Cornwall in its relation to local coloring, somewhat resembled the old pocket boroughs in which the County participated—the outsider was not permitted to share in its mysteries. Under the 'cost book' system such modern questions as 'ore reserves,' 'parity of assets,' 'redemption of capital,' &c., do not trouble the 'adventurers' or shareholders.

If money is required to prove a likely piece of ground, or the engine bob develops an unsuspected flaw, or a new boiler is decided on—the financial exigencies are met by a 'call' just sufficient for the wants of the moment. Profits when accrued are divided up to the hilt; with no provision for a rainy day, a not very prolonged run of bad luck exhausts the resources or the patience of the adventurers, and the 'bal' being 'skat,' the pitwork is drawn, the machinery sold, and the erstwhile scene of activity becomes a desolation.

But there is a reverse to the picture. The records of the past abundantly prove that Cornishmen were able to triumph over the difficulties of finance as well as those imposed by nature. Mr. Peter Watson, than whom there is no better exponent of Cornish mining in its most acceptable form, when presiding over the Wheal Grenville meeting the other day, reminded his audience that the Carn Brea district alone—the 'Rand of Great Britain'—had produced from twenty-five to forty millions sterling. The meeting in question was a characteristic one—breezy and hopeful. The chairman and manager each had a pleasing account to give for the past twelve weeks—178¾ tons of black tin sold, which realized £17,279. Net profit £3,934 after deduction of lord's dues, amounting to one-fifth of the profits. The 6,000 shares stood at about £9½ in the market. Dividends amounting to £2 8s. per share had been paid during the year, or about 25% on the market price. At the deepest point, 320 fm., the first western shoot had been struck, worth —for the seven fathoms explored—£50 per fm. Other improvements were reported. Up to the present Wheal Grenville operations have been limited to the flat lode. The Polgine lode in the southern part of the 'sett,' worked successfully fifty or sixty years ago, is now receiving attention. It has been unearthed in clearing out the old workings and found to be three to four feet wide with an average value, where cut into, of 28 lb. black tin per ton. Wheal Grenville as a 'cost book' mine has introduced the daring innovation of a reserve fund!

In addition to these good things, the committee were able to give their 'adventurers' the chance of subscribing for shares in Condurrow United Mines Ltd., a company formed under Wheal Grenville auspices with a capital of £30,000 in 10s. shares. After providing only for the legal and preliminary expenses in forming the company, the whole of the remainder of the subscribed capital will be available for the mine, as there is no purchase money to be paid. The lease is direct to the company from the owner at a minimum rent of £50 merged in dues amounting to one-eighth of the profits, until the entire subscribed capital is repaid in dividends, increased to one-sixth afterward. This mine is situated on a strip of choice tin ground extending for nearly one and a half miles on the run of the lodes, east and west. The property is immediately surrounded by Dolcoath, Wheal Grenville and South Condurrow, which have yielded profits totaling £1,250,000, while the many other mines in the vicinity are said to have given £1,500,000 more. The mine itself, formerly worked as the Great Condurrow under the 'cost book' system to a depth of 300 fm., is said to have paid large sums in profits, until 1873, when it was stopped owing to the drop in the price of tin from £120 to £82. The market, hungry for new business, will keenly watch the progress of this new development in the Cornish tin mining industry, freed from the fetters of the old 'cost book' system. The established mines also under limited liability—Dolcoath, Carn Brea, Tincroft, &c., in which rich finds have recently been reported, are making their place slowly on the London stock exchange. Considering the unlimited quantity of tin said to be awaiting development in that famous district, and the high price of the metal, the progress made is certainly not startling as regards increase of output. In the department of mechanical treatment there is also much to be done, as exemplified by the recovery of tin by the 'streamers'—which in 1904 amounted to 12% of the entire production of the County.

Gallant little Wales has been heard lately bidding for the favor of the mining investor. The St. David's Gold Mines, (1903), Ltd. formed with 60,000 shares of 5s. each, started with £5,000 only for working capital. Previously and under the existing company, this property produced in seven years 101,124 tons of ore which yielded 51,990 oz. bullion, realizing £193,588 at a working cost, not including developments, of £86,155. During 1905 the main lode fell off in output of rich ore, but there is still a large body of ore that can be relied upon for a fair average profit. The chairman, at the annual meeting, said there were many other mines in the country which might profitably find work for miners who are attracted abroad. He lamented the fact that for promoters and the public, distance lends enchantment; out of a list of four hundred Transvaal mines he found ninety were paying dividends; two-thirds of these companies could not rival Wales.

The King's speech has not revived the drooping spirits of the Kaffir market. The letters patent granted for an intermediate stage of representative government are withdrawn and a new constitution for the Transvaal and the Orange River Colony is to be drawn up providing for responsible government. Thus an inevitable delay threatens the South African gold industry. Elections being postponed to December, the legislative assembly cannot meet before February, 1907. Till then licenses for importation of Chinese labor will cease. Meantime it is said outstanding licenses provide for a balance of 10,000 coolies to arrive.

A spurt has occurred this week in Great Boulder Main Reef, Ltd. (W. Australia). After working through a poor zone several hundred feet deep, pay-ore has been struck, likely to be the forerunner of important developments. At the new 1,500-ft. level a cutting put in west from the north drift on the main lode at 90 ft. has pierced the wall for two feet, and the breast is still in ore averaging two ounces gold. This company is an offspring of the Venture Corporation, whose progeny in different parts of the world are going much better than heretofore. Under the present bold and resourceful leadership, the parent company's fortunes are again in the ascendant.

An interesting feature of the Royal School of Mines dinner last week was the presentation of plate with an address and album of signatures from past and present students to Professor Judd on his retirement from the chair of geology. After proposing the toast of the evening—that of 'The School of Mines,' the chairman, Professor S. Herbert Cox, in the course of his speech referred to the much debated scheme for the future of the school. He said he understood the recommendations of the departmental committee (which they would all be pleased to accept) to mean;

(1) The title of the Royal School of Mines is to be preserved.

(2) It is to be one of several schools, such as civil engineering, chemistry, &c., which are to have their headquarters at South Kensington.

(3) Each school is to provide higher instruction, and grant diplomas in its respective subjects.

(4) The diploma is to remain that of Associate of the Royal School of Mines.

(5) As there are a number of preliminary subjects which are common to all branches of scientific education, a knowledge of these must be acquired by students before entering upon the course at the school.

(6) A central institution will provide an approved two years' course which will satisfy these requirements, but this preliminary work can be done elsewhere if more convenient.

TORONTO, Canada, February 28.

The first instalment of the promised legislation respecting mining was presented to the Provincial Legislature on the 26th inst. According to this bill the Department of Lands and Mines will be reorganized, being known in future as the 'Department of Lands, Forests and Mines.' The status of the present Bureau of Mines will be raised and its scope extended by placing it in charge of a deputy minister; Mr. T. W. Gibson, the present director of the Bureau being promoted to that position. The effect of this will be to increase his responsibility and give him a freer hand in keeping with the growing importance of the mining industry. This bill is merely the preliminary to the more important measure promised for some time amending the present mining regulations, which were framed when the mining interests of Ontario were yet comparatively insignificant. The details of the measure have not yet been completed, but some of the leading provisions have been made public. The number of mining divisions will be increased. Under the old system everything was centralized at Toronto. All applications for the location of claims had to be filed here, putting applicants to much expense and inconvenience, and giving rise to charges of official favoritism and the forestalling of claims through political influence. The only exception was the mineral district of Michipicoten, which was set apart as a mining division about ten years ago. Last year the Temiskaming mining division was created, including the Cobalt area, but outside of these localities all proceedings requisite to the taking up and transferring of claims, etc., had to be taken in the department at Toronto. The principle of de-centralization, partially recognized in the cases of Michipicoten and Temiskaming, with manifest advantage to the industry, is to be extended by the organization of four or five other mining divisions with a recording office in each where all applications must be filed. The feature of the measure which gives most satisfaction to miners is that there will be no royalty or percentage tax on the output of mines. A small land-tax will be levied on all claims whether productive or not. The size of claims will be 40 acres, which will be sold at $2.50 or $3 per acre in surveyed districts and at about $2 per acre in unsurveyed areas. In addition to the annual tax, it is proposed to exact certain working conditions as a means of checking merely speculative enterprises. Refining of silver-cobalt and nickel ores will be encouraged by government aid in some form. These are the main outlines of the bill in course of preparation, in which the influence of the mining convention held in December last and the subsequent agitation of the subject by mining men is very apparent.

The spring rush to Cobalt is setting in earlier than was anticipated and large numbers of mining prospectors, speculators and others are already on the ground. Preparations are making for an influx such as has never been witnessed in the history of Canadian mining. Meantime work is being steadily continued at the producing mines and large shipments of ore are being made to New York. The extensive timber limits owned by Gillies Bros., lying immediately south of the mining area, a portion of which is known to be rich in silver ore, have been a cause of much difficulty, as prospectors have been prevented from locating claims on this tract. The limit-holders have no claim except to the timber and arrangements have been made with the Government, under which the mineral-bearing portion of the limit will be cleared as rapidly as possible. Some 800 men are engaged in the work, and in a few weeks the valuable timber will have been removed. This part of the limit will then be thrown open, but the problem which is engrossing the attention of the Government is the manner in which this is to be done. As hundreds of people know the localities where there are valuable mineral outcrops, to throw it open for prospecting in the ordinary way would result in a general scramble for priority, entailing possible violence and bloodshed and certainly endless confusion and disorder. A suggestion much favored is that the Government, in view of the special circumstances of the case, should depart from the usual practice and dispose of these locations at public auction.

The question of the treatment of the Cobalt ores in Ontario, or at least under conditions which will secure to the shipper larger returns than are obtained at New York, is in a fair way of settlement. W. G. Trethewey, one of the largest Cobalt mining operators, and John McMartin, of Cornwall, are organizing a company to establish a silver refinery at Hamilton, Ontario. They have secured the property of the former Hoepfner Refining Co. in that city, and will treat ore by a process in use in Saxony, Germany, which has proved satisfactory. Experiments undertaken in the smelting of Cobalt ores in England have yielded encouraging results. A well-known firm secured a trial shipment of 20 tons of ore and has made an advance payment of £100 per ton, promising further remittances as other valuable constituents are extracted from the ore. This encourages the hope that a market can be found in England in which the value of the nickel, arsenic and cobalt in the ore, now largely ignored by New York buyers, will be recognized.

DENVER, March 6.

A great deal of unfavorable comment is heard concerning business conditions at Cripple Creek, which in the main is both thoughtless and unjust. Like every other mining camp, Cripple Creek was commercially overdone in nearly every branch of business and the general re-adjustment that is now taking place is misunderstood. The district has a total estimated population of over 20,000, less than one-fourth of which is employed in the mines. The men are saving their money. 'High grading' (ore stealing) has been weeded out, to a large extent, and while it can never be known how much was extracted from the mines in that manner, it was surely the source of a part of Cripple Creek's apparent business prosperity. The 'high-grader,' as a rule, lives on the fat of the land; he is a good spender and his social status depends more upon the moral atmosphere of the camp than upon his proclivity to annex a part of the pay-streak. A prominent business man of Cripple Creek recently said that about 10,000 people would represent the future permanent population of the district. The camp may shrink to that number, but its actual resources warrant the opinion that it is sure to grow in population again. The mine-owner is no less a 'kicker' than the merchant, but he lays the cause of all his woe to the 'smelter trust.' Whether his trouble is real or imaginary, it has developed a seemingly fixed purpose to adopt new tactics, which, if carried out, will have a far-reaching effect on the future of the camp. While there is no concerted movement, there is a general intention and preparation to treat all ore locally or by works controlled by the mining companies. Cyanidation is the process most likely to be generally used though the bromine treatment is also favored by a few. The great drawback to local treatment by cyanide is the cost of roasting; however, there is an immense tonnage of oxidized ore yet to be worked.

The Portland mill, near Colorado Springs, and the Economic mill, of the Woods Investment Co., both chlorination works, have been running successfully for a number of years. Of the older mills in the district, owing to fire and removal, scarcely a vestige remains. The Copper Mountain mill and the plant built at Gillette last year are both idle. The Homestake mill is closed, while situated close to it, the Ironclad Mill Co., with its 100-ton plant, commenced to treat custom ore the first of this month and is planning to increase its capacity to 150 tons per day. The Wild Horse mill is not credited with any great success. The old Van Fleet sampling works at Goldfield has been converted into a cyanide mill and is running successfully on custom ore. The mill at the Los Angeles, destroyed by fire some time ago, is not likely to be rebuilt. The Santa Rita mill, treating the ore of that property exclusively, is being doubled in capacity. The new mills now under construction are the Golden Cycle, at Colorado City, the Pony gulch mill, of the Little Giant Mining & Milling Co., and the Mineral Hill plant, of the Wishbone Gold Mining Co.

Among the smaller mills, that of the Anaconda is perhaps the most noteworthy. It has a daily capacity of 100 tons and is conducted by Dr. Pascal Craig, one of the owners, who has finished a successful run of several thousand tons of surface and dump ore from the Anaconda's property. The mine management states that the average value of the ore treated was $3 per ton, and that this was handled at a profit. Dr. Craig is now arranging to treat custom ore.

The Pony Gulch mill, with a capacity of 200 tons, was nearly completed when destroyed by fire on January 13. It is now being rapidly re-constructed for a 400-ton capacity. It is designed to treat ore belonging to the company; however, it is the intention of the management to increase the capacity later to 1,000 tons and treat custom ore, should the first installation prove successful. Some of the mills of the district are idle, and to understand the reasons would be to learn the inside history of the companies and the men who built them, to sift out the stock schemes from the sane enterprises and to know of mistaken ore values. New mills are being built and others are projected by the hard-headed men interested in the district, with no ulterior motive than to gain profit from custom work. Notwithstanding the number of mills that are built not to run, there are a large number of legitimate enterprises on foot, which, when carried out, will make a new camp of Cripple Creek.

The open rates of treatment levied by the 'trust' mills are: A minimum of $5 for ore having a valuation up to $10 per ton; $6.50 for ores having a valuation of $20 to $25 per ton, with a minimum railroad freight of $1 per ton. Your correspondent is not at liberty to mention names or give full data, but he has seen a contract, given by one of the local concerns, which nearly cuts the fixed charges in half. Counting the entire fixed charges—that is, wagon haul, sampling, railroad freight

and treatment—the outside mills would have to cut their treatment charge from $5 per ton to $1.70 per ton, on the minimum, to meet the figure. If the oxidized ores can be treated at so low a rate, making an actual difference of $3.30 per ton on $10 ore, the roasting question does not look so serious, and it requires no great foresight to see that eventually the contest will be between mine-owners and railroads, instead of owners and the 'trust.'

The partial closing of the Findley Consolidated Mining Co.'s mines on the first of this month is by no means construed to mean that these mines are out of ore, but that the Findley Co. is looking for better treatment rates, and it is reported that, hereafter, its output will go to the Golden Cycle mill. During the time which will intervene before the completion of that mill, or until the Findley secures another equally good contract for treatment, a small force will be kept on development work.

SALT LAKE CITY, March 5.

The stockholders of the Bullion Beck & Champion Mining Co. have elected a new board of directors to serve during the ensuing year, which has organized with Philo T. Farnsworth, president; Joseph F. Smith, vice-president and treasurer; M. C. Morris, secretary; who, with James A. Cunningham, Philo T. Farnsworth, Jr., H. C. Lund and S. W. Riter, constitute the board of directors. All excepting the latter are of Salt Lake. The company's mine is one of Tintic's oldest producers, and is worked principally by lessees.

The shipments of ore from Park City the past week aggregated 5,224,000 lb., as follows: Silver King, 2,139,000; Daly-West, 1,150,000; Kearns-Keith, 86,000; New York Bonanza, 100,000; Daly-Judge, 1,218,000; Daly-Judge (zinc middling), 531,000.

At the Skylark copper property in Beaver county a winze from the main tunnel has broken into copper pyrite.

Developments at the Silver King Consolidated at Park City are being watched with interest. The double-compartment shaft has cut a mineralized ledge. The formation is similar to that in the old Silver King.

The management of the Galena King mine at Stockton has resumed development and will drive the Honerine drain tunnel to connection with the main lode. The Galena King Co. has done little to develop its property since the formation of the Honerine Tunnel Co., in which it is interested, which project was undertaken to drain the principal mines of the camp. The Galena King Co. has $100,000 in the treasury with which to prosecute exploration.

The new equipment at the Yampa smelter in lower Bingham canyon, in process of installation, will soon be completed. The equipment consists of a second reverberatory and eight McDougall furnaces. These will probably go into service in April.

The management of the Century mine, in the Park Valley district, Box Elder county, reports that the mill at that property will begin crushing in May. The company has employed the past year in the development of the mine. A crosscut run to the north has opened milling ore.

The mill and electric-power plant of the Sevier Consolidated Mining Co. in the Gold Mountain district are working satisfactorily.

A new mining camp, Gold Butte, situated in the extreme southeastern portion of Lincoln county, Nev., is attracting attention at Salt Lake. About a year ago a syndicate of Salt Lake men sent a prospecting party to Nevada in charge of J. F. Gibbs, who had been mining in the Gold Mountain district, Utah. Mr. Gibbs went into the St. Thomas mining district, 45 miles south and east of Moapa station, on the main line of the San Pedro, Los Angeles & Salt Lake railroad. He found ledges showing free gold on the surface and located a group of mining claims and also a spring, explored the veins, which were from one foot to 15 ft. in width, carrying streaks of high-grade gold ore. Late last fall, another outfit, in charge of W. C. Sharpe of Tucson, Ariz., came in and located an adjoining group; still later, a syndicate of Kimberly, Utah, citizens, mostly officials of the Annie Laurie mine, who had heard of the new district, sent in another outfit, which secured promising locations. During the past few weeks others have gone into the region. Application has been made to the Postoffice Department for a postoffice, to be called Gold Butte, with semi-weekly mail service. Several companies have been formed and are actively developing, it is said, with satisfactory results. The Gold Butte Co., formed to take over the Gibbs locations, is getting out a high-grade shipment, the ore having been taken from open trenches. A general store has been established.

The City Rocks mine, at Alta, is shipping, and during the week marketed a carload that showed 7% copper, 20% lead, 20 oz. silver and $1.60 in gold.

The Holland Gold Mining Co., developing a property near the Sevier Consolidated, in the Gold Mountain district, Utah, will soon put in a compressor. Gideon Snyder, of Salt Lake, is secretary.

The smelter of the Utah & Eastern Copper Co., at Shem City, Washington county, is in operation. Early last year the mine ceased production, owing to the caving of the main shaft, which was so badly damaged that the management decided it would be more economical to drive a tunnel, cutting the orebodies lower. This was done and recently connection with the old workings made. The property is in shape for steady production.

The experts of F. Augustus Heinze, who have been investigating the Dalton & Lark mines at Bingham, operated by the Bingham Consolidated Mining & Smelting Co., have finished their labors and are at the Eagle & Blue Bell mine, the Bingham's Tintic possession. The work of the Heinze men at the Dalton & Lark has been checked up by Robert C. Gemmell, general superintendent of the Utah Copper Co. These examinations are supposed to be in the interest of Thomas F. Cole and associates.

The Pittsburg Consolidated Mining Co., at Alta, has a bond on the property of the Pioneer Mining Co., at Alta, which owns a tunnel site. It is proposed to extend the tunnel, now 400 ft. in, to the Pittsburg orebodies, which will be cut at a depth of about 900 ft. under the present workings.

The Swansea mine, in the Tintic district, is sending to the smelters 1,000 tons of argentiferous iron ores monthly. An official of the company has stated a dividend will be announced during the month.

The Alexander group at Stockton, recently purchased by a Salt Lake syndicate, will form the basis for a new company to be organized. The property adjoins the Black Diamond.

Late developments at the Odin mine at Park City indicate that the camp is going to have another shipper. A drift to the west has opened into a shoot of ore that has a gross value of $60 per ton. The property is owned largely by Park City men, among them being Henry Walsh and Peter Kaas.

The Ohio copper mine in Bingham is being examined by W. H. Wiley and assistants for Samuel Newhouse and the Venture Corporation of London. F. W. Baker, representing the latter as chairman of the executive committee, conferred with Mr. Newhouse recently about the property.

The monthly payroll of the Tintic district aggregates about $95,000.

At the Utah-Apex mine in Bingham last week, an important strike of copper ore, of shipping grade, was made in a drift west from the Parnell tunnel level.

The recorder of Utah county has filed a deed from E. W. Clark, as receiver of the Overland Gold Mining Co., to Denman Blanchard of Boston, the consideration named being $37,500. This property is situated in the Camp Floyd mining district and the orebodies are being opened by a new shaft, preparatory to the starting up of the mill. The ore is low grade and can be treated successfully by the cyanide process.

Articles of incorporation of the Ogden Leasing & Development Co. have been filed. The directors are C. H. Hussey, Parley M. Parry, Francis L. Woods, John J. Schwartz and S. L. Ives, all of Ogden, Utah.

Details are being arranged for a bond issue for the Bingham Central Mining Co. at Bingham, which is to be the scene of a vigorous campaign shortly.

The stockholders of the Mammoth Mining Co. will meet in special session on the 31st inst. for the purpose of discussing and deciding on the matter of re-incorporating the company, this time under the laws of Nevada, instead of Utah, as at present. It is planned to have 1,000,000 shares of the par value of $1 each; 400,000 shares to be issued to the present shareholders and the balance to go into the treasury. The officers of the company desire to get the advantages of the Federal courts in event of litigation.

Tintic district mines shipped 183 carloads of ore to the Salt Lake smelters last week. The shippers and amounts being: Dragon Iron, 10; Beck Tunnel, 9; Eureka Hill, 16; Eagle and Blue Bell, 8; May Day, 3; Brooklyn, 3; Swansea, 5; Uncle Sam, 4; Yankee Consolidated, 6; Bullion Beck, 13; Gemini, 30; Ridge and Valley, 3; Centennial Eureka, 45; Ajax, 5; Black Jack, 4; Carisa, 4; Lower Mammoth, 2; Mammoth, 13; Victor Consolidated, 1.

HELENA, Mont., March 5.

Mining in this part of Montana is more active, and gives better promise than for several years. The camps tributary to Helena are small and scattered; but in the aggregate there is more ore shipped, and larger returns from ore milled within a radius of 35 miles, than for the past six or seven years. Prospecting and mining development have not been so great as to cause anything in the nature of a boom, but steady, determined effort to develop mining resources has been made with substantial returns.

Perhaps the most important mining operation near Helena is the revival of the old Whitlatch mine at Unionville, four miles south of Helena. Nearly two years ago work of development was begun on this old bonanza, after an idleness of 27 years. The new 20-stamp mill, driven by power electrically transmitted, has been built, and was put in operation January 1 last. This mill is now running steadily and producing a goodly amount of gold bullion, which favorable result is likely to stimulate the re-opening of other gold-quartz mines at Unionville.

The Spring Hill mine, owned by the Pittsburg & Montana Copper Mining Co., situated one-half mile north of the Whitlatch mine, is making regular shipment of 50 tons daily to the Butte smelter of said company. The ore is pyrrhotite, and in addition to its value for fuel in the smelter, carries enough gold to pay mining and transportation charges.

At Rimini a number of leasers are working and small shipments of high-grade silver-lead ore are coming in from time to time to the East Helena smelter.

The M. & M. mine on the porphyry dike, nine miles from Rimini, has recently finished a 10-stamp quartz mill and is doing very well with the prospect of an enlarged plant at an early date.

The Bullion mine on Cataract creek is furnishing ore to its concentrator and it is reported that eight miles of railway will be completed during the coming summer to connect its smelter with the Great Northern railway at Basin. The same line of railway may later extend up Cataract creek and northerly across the divide and down the Blackfoot to a connection with the Northern Pacific railway at Elliston. This enterprise, if completed as promised by its promoters, will be the means of opening up an extensive mineral district. A large number of mines, from 10 to 14 miles south of Elliston, have produced in the past considerable quantities of shipping ore, but these mines now depend upon the large tonnage of concentrating ore which can be furnished as soon as transportation facilities are afforded.

The district to the north of Elliston, of which Silver Camp is the center, is active, and much larger shipments during the coming summer are promised.

In the immediate vicinity of Lincoln, a gold-milling proposition, owned by John A. Rowand, is being developed and milling operations on a small scale will begin early in the spring.

That well-known producer, the Jay Gould mine, has been sold to Chicago capitalists by A. W. Martin. This sale will mean an immediate resumption of milling operations in the company's 30-stamp mill, which has been idle since the latter part of December pending this sale. The price is stated to have been $450,000. The Jay Gould has always been recognized as one of the paying mines of this section. For a number of years it was operated by Helena men. It is a free-milling gold proposition. The last clean-up is stated to have yielded $27,000. The new corporation will be known as the Gould Mines Co. The men principally interested in the new concern are large holders in the Whitlatch Co., which is successfully operating the Whitlatch-Union mine near Helena. Canoll & Martin are also interested in the new company. F. A. Ross, of Chicago, will be general manager of the company, and F. L. Sizer, of Helena, will be consulting engineer.

At Elkhorn the Iron mine, owned by John Rothfus, continues its regular shipments of iron ore to the smelter, and a large body of pay-ore has been developed at this property. The Elkhorn mine, owned or controlled by J. H. Longmaid, will resume operations very early in the spring, the higher price of silver making it possible to mine this ore at a profit, and considerable development work in the camp is anticipated.

Numerous small silver-lead mines are being operated in the Basin and Cataract districts, and also near Wickes, so that the aggregate shipments reach a much higher tonnage than for the last six or seven years. Some attention is also being paid to the zinc content of the ores, and it is probable that when cheap transport is afforded by the completion of even a portion of the Basin & Elliston railway, some reduction plant capable of saving both the lead and zinc will be installed at or near Basin.

The fact that a larger market for electrical power is now assured explains the desire of the Missouri River Power Co. to complete its second dam, now under construction on the Missouri river, 17 miles north of Helena. Of course it is known that by far the larger part of this power will be consumed in Butte, but there is great encouragement to the smaller mining operations in this vicinity, because of cheap and suitable power, which can be furnished by the Missouri River Power Co. next fall, when its second dam will have been completed. The old plant at Canyon Ferry develops and transmits 10,000 h.p. and the new plant will produce 15,000 h.p. Several of the smaller companies operating within reach of these two power plants are considering the building of their own transmission lines and installation of electric power as soon as it can be furnished from the new dam.

The Winston district, 20 miles east of Helena, is receiving considerable attention. The H. & H. mine, closed down for many years, was re-opened about a year ago and very good results from new development are reported. The company operating this mine is sinking the main working shaft deeper and also sinking another working shaft on a parallel vein, and the mine will become a regular shipper again as soon as this shaft work is completed. The East Pacific mine, in the same district, is running its 50-ton concentrator on the old dumps of second-class ore, and making shipment of concentrates to the smelter at East Helena. Work of mine development will be resumed here in the near future.

ALASKA.

The Rosella Hydraulic Mining & Development Co. will dispatch its first crew of men from Victoria, B. C., to Rosella Creek, near Wrangel, about March 1. The machinery for the company's hydraulic plant was taken in last year and will be set up as soon as the snow disappears.

F. C. Hammond and others have located 1,000 miners' inches of water at Sheep creek, near Juneau, for the purpose of developing electric power for mines in the Juneau district. Mr. Hammond reports having contracted to supply the Alaska-Perseverance Co. with power.

The Conrad Consolidated Co. is preparing to build a surface tramway from Windy Arm to the Venus mine at Conrad, near Skagway. —— Work will begin on the Dail group, at Conway, and on the Ruby claim, about March 15.

Bedrock has been found at a depth of 65 ft. on No. 8, at Cooper gulch, near Nome.

F. McIntosh and others, owning a number of claims on the tundras on Penny river, near Nome, have let a number of lays on the property and prospecting is going on.——Bayles & Wentworth and Sinclair & Johnson have sunk holes to bedrock near Nome and are planning to instal machinery if the present pannings hold out. ——Mr. Ivey, formerly collector of customs at Juneau, is prospecting with a large force and steam thawers on a claim near Penny river at Nome. Several holes have been sunk to bedrock.——Mr. Stout and party are prospecting near the foot of Jess creek, in the Nome district.——The Bartells Tin Mining Co. has awarded a contract to L. Meyers for the construction of a 4 by 7-ft. tunnel through a hill of granite to reach its tin ledge in the Cape York district.——The Wild Goose Co. is doing considerable winter work in the Council district, near Nome.

ARIZONA.

Cochise County.

The Saginaw mine, near Douglas, will be unwatered and drifting commenced on the 900-ft. level. The new pumps are in place.——The main shaft of the Shattuck & Arizona mine, near Douglas, is being enlarged and will be equipped with a new hoist and compressor.—— The Naco Smelting & Refining Co. has contracted with the citizens of Naco to begin work on a smelter of 250-tons capacity at Naco before April 1.——M. Carter has bought at sheriff's sale the property of the Dragoon Mining Co., in the Dragoon mountains, near Douglas. ——A large Nordberg hoist was installed last week at the Junction mine, near Lowell. An 85-ft. steel gallows frame is arriving and will be set up when all the parts have reached the mine.——It is reported that the Sullivan Copper Mining Co. will instal pumping machinery at the Sullivan group, near Paradise.

The Bisbee miners on the 5th inst. voted on the question of organizing a local union of the Western Federation of Miners in Bisbee. The vote stood 2,200 against the union proposition and 428 in favor, practically every workingman employed by the Bonanza Circle Co. and the Copper Queen voting. The election was the result of the efforts of an official organizer for the Western

Federation of Miners, who has been here for two months encouraging the union movement. A mass meeting of miners held at the Opera House last week decided to leave the question to a vote of the miners. The miners at Bisbee receive union wages.

C. L. Andrews has purchased 150 mules to be used in hauling ore from the Transvaal Copper Co.'s mine to its new smelter, at Cumpas.

Gila County.

It is given out that the fire in the Interloper shaft on the Old Dominion mine at Globe has been smothered. A new furnace has arrived for the Old Dominion smelter. ——Work has been commenced on the Iron Cap mine, near Globe. The shaft will be sunk 600 ft.——Machinery has arrived for the concentrator for the Pinto Creek Mining & Smelting Co., of Globe.——The new converting plant on the Shannon mine, near Globe, was put in commission last week.

Graham County.

S. S. Campbell, of the Naravilla Mining Co., is in Solomonville to open the company's mines, eight miles north of Solomonville. —— C. E. Stevens, of the Columbus Copper Co., has let a contract to drive a tunnel an additional 500 ft. at the company's mines, near Clifton.

Mohave County.

F. Vasquen, of the Argo mine, near Kingman, states that work will be resumed at that mine within a few days.

Pinal County.

The old smelter at the Ray mine, at Kelvin, was burned a few days ago. The smelter was erected 10 years ago, but was never operated.——The Big Lead Mining & Smelting Co. is figuring on the building of a concentrating plant near Ray.

Machinery is now on the ground for increasing the capacity of the Desert Queen plant, at Casa Grande, to 30 tons, the present capacity being about 15 tons. A Tremaine mill for the treatment of slime and additional cyanide machinery are to be installed. Work is to be started on a double-compartment shaft, the previous work having been entirely on the surface.

Yavapai County.

D. E. Andrews and E. T. Frank have concluded the purchase of the Tam O'Shanter group of mines near Crown King.

The Rigby Mining & Reduction Co. is making preparations to start its new plant, at Mayer.——The Treadwell smelter, near Mayer, will begin operating at full capacity shortly.

John Kinney and E. F. Cullerton are preparing for the development of the Kinney mine, in the Big Bug district, near Poland.——A. L. Lee and John Harlan have purchased the Hopper group, on Cherry creek, near Prescott.

W. J. McMahon is installing new machinery for the Pittsburg-Jerome Mining Co. at Jerome. —— J. T. Neff, president of the Goddard Mining Co., has purchased five claims between the Oro Grande and the Goddard properties, near Prescott. —— H. A. Mills, of Colorado, has purchased the American Flag, Morning Star and Davis mines in the Big Bug district, near Prescott. Lumber has been ordered for camp buildings. Hoisting and other machinery is to be installed.

The French Lilly mine, at Crazy Basin, near Prescott, is being unwatered.——A 35-h. p. engine and a 150-h. p. gasoline engine are being installed on the Rincon properties, near Congress. Development will be delayed until the larger engines are installed.

CALIFORNIA.

Alpine County.

The holdings of Mr. Curtz at Loope have been sold to Reno parties, who, it is reported, will spend $100,000 on developments.

Amador County.

The engine and boiler at the Phœnix mine, near Wieland, have been sold to John Strohm of Jackson.—— Since the breaking of the shaft at the Mitchell mill, near Jackson, only five stamps have been running.—— The mill at the Jose Gulch mine at Butte City, near Jackson, is being put in order.——The Treadwell mine, eight miles east of Sutter Creek, is to be equipped with a 10-stamp mill.——Mr. Helm has let a contract for sinking on his mine near Ione.——J. Whaley is to resume operations on the Taylor Slide mine at Fort John, near Jackson.——J. Troax and Wm. McVay have begun operations on their placer mine at Fort John.

Butte County.

J. W. McFarland and E. Thatcher are preparing to begin development work on the J. M. Hutchinson claim, on Little Butte creek, 12 miles from Chico.

Calaveras County.

The Chris Anderson drift mine, near San Andreas, together with the machinery at the mine, is advertised to be sold at commissioners' sale, on March 19, to satisfy a judgment of $569.35.

Fresno County.

The Copper King Mining Co. has contracted with the San Joaquin Light & Power Co., of Fresno, for power to be supplied to the company's mines, east of Fresno, over a long-distance transmission line.

Inyo County.

Flynn & Levi report having sold their half interest in the Augerbury holdings in Wild Rose canyon near Ballarat. The new owners have guaranteed to expend $35,000 in development, to put in a 10-stamp mill, and to pipe water to the mine.——The tunnel on the Harris claim in Wild Rose canyon, near Ballarat, has been completed to the distance of 150 ft.——The Golden Key Mining & Milling Co. has purchased 23 claims from E. F. Koster, J. R. Ingram and others, in the Wild Rose district near Ballarat. The new owners will continue development on a portion of this property.

The Mt. Whitney Mining Co. is putting its mill in shape, at Lone Pine, near Independence, and will begin operations shortly.

Kern County.

(Special Correspondence).—F. A. Fickert of Bear valley, near Tehachapi, has returned from San Francisco, where he closed the sale of his zinc mine, which has been under consideration for some time. The development of the property will be begun as soon as possible.

Tehachapi, March 4.

R. L. Deakins and P. J. Bresnaham, owners of the Fairy claim in Fiddler's gulch near Randsburg are shipping in men and supplies and will begin development.—— The Zenda mill near Amalie, to which 10 stamps have been added, started up last week.——H. H. Blood and others of Bakersfield will begin operations at the mill at the Gold Peck mine about June 1. Twenty carloads of machinery have been taken to the property.

Charles Taylor and Henry Giondoni have leased the 600 ft. of the east end of the Little Butte mine, at Randsburg, to January 1, 1907, including the machinery, shaft and buildings.

The Butte mine is working in rich ore at a depth of 225 ft. The deepest shaft on the mine is over 600 ft. and shows valuable ore at the bottom.

C. S. Pillor, manager of the St. Elmo mine, near Randsburg, reports that they are drifting at the bottom of the 265-ft. shaft to prospect the vein.

Mono County.

The Standard company at Bodie is developing the new strike made some weeks ago in ground known as the old Bodie mine.

Nevada County.

The Posey Canyon Gravel Mine Co. has secured a bond on the Mother Mitchell claim west of Grass Valley and will run a tunnel to tap the channel.——The Ethel mine in God's Country near Grass Valley has been partially closed down on account of the shortage of fuel. The drift in the mine is being extended.

Work is to be resumed on the Deadwood mine, near Nevada City. Manager Esselstyn is in San Francisco completing the preparations. The tunnel has been cleaned preparatory to extensive operations.——Frank Ensensperger has assumed the management of the Union Hill mine, near Grass Valley, which was sold a few days ago. The leasers, who have been working the mine, have been stopped and the new owners will begin sinking and drifting.——It is reported that a six-foot ledge has been encountered in the extension of the shaft of the Central mine, near Grass Valley.

An ore shoot assaying $200 in gold per ton is reported in the Union Hill mine. The vein is 24 in. wide. The ore is white and contains a large quantity of pyrite and free gold. The mine was recently purchased by San Francisco and Los Angeles capitalists, who took over the lease from the men working it, paying $3 a day for the time the leasers had put in. The leasers were drifting toward this ledge when the mine changed hands, and were only a few feet from the shoot. The purchasers have made arrangements for a new mill, and a large force put to work. A shaft is to be sunk.

The Home mine will be closed down, owing to the Champion-Home litigation set for trial on April 10. The Home people announced that they intended to close down as soon as the case should be set for trial and that the mine would be kept closed until the termination of the trial. For that reason they asked that an early date be named. The trial, it is thought, will occupy several months.

Riverside County.

Frank Cram and J. H. Patee have returned from San Francisco, where they purchased a 25-ton mill for the Brooklyn Mining Co.'s mines, at Dale. The mill is expected to be in operation by April 1.—— The Gold Quartz Mining Co. is sinking a 500-ft. shaft on one of its claims, 18 miles from Dale.

The Borland Mining & Milling Co. has contracted to sell its claims in Silverado canyon, 22 miles east of Orange, to C. D. Maze and a French company, who agree to do 1,000 ft. of tunneling within six months. A 42-ton concentrator, operated by gasoline, is now being put in.

Placer County.

Forty more stamps will be added to the 20 stamps now in operation at the Three Stars mine, seven miles west of Auburn. While these are being added new levels will be run.

The Buckeye mine, near Forest hill, will be re-opened. ——The Baltimore mine, at Forest hill, has been practically closed down to permit of extensive repairs and development.——The Proper Fraction quartz claim, in the Canada hill district, northeast of Forest hill, is advertised to be sold at sheriff's sale, on March 24, to satisfy a judgment of $1,779.69.——The Polar Star hydraulic mine, at Dutch Flat, is to be re-opened under new management. The mine has been closed since last spring. Preliminary work is now being done.

Vail & Burton report having sold the Burton mine, two and one-half miles east of Rocklin, for $7,000.

Plumas County.

(Special Correspondence).—G. S. Tyler is developing two ancient gravel channels near Quincy. These channels have a difference of 300 ft. in elevation, the lower containing 'blue' gravel, the material being largely volcanic, boulders, cobbles, sand, etc., with some slate and quartz. The prospect in this channel is said to be promising. The upper channel has as yet little development. There are many miles of lava-capped channel in this section of the State which have not been explored. The work under the direction of Mr. Tyler is on both sides of the middle fork of Feather river, above the mouth of Nelson creek. The modern streams and their bars were worked in the early '50s. Nearly all the ancient channels are in the forest reserve.

Quincy, March 4.

San Luis Obispo County.

Another shaft will be sunk at the Klua quicksilver mines, near San Luis Obispo.

Shasta County.

Walter Van Matre, superintendent of the Washington mine near French Gulch, begun drifting on the new 200-ft. tunnel last week. He reports that additional stamps will probably be placed in the company's five-stamp mill soon.——B. F. Rodgers of the South Fork mine at Igo has encountered the Pilchuck ledge at a depth of 300 ft. He will now begin a raise to strike the Chicago ledge.

E. Newhouse, of the American Smelting & Refining Co., has been made manager of that property at Balaklala, near Kennett.——P. Ramsey, of Kennett, reports having re-opened an old prospect about three miles from Kennett.

Siskiyou County.

The Yreka Creek Gold Dredger Co., which has been drilling prospect holes near Yreka, has definitely located the Bed Rock at a depth of 30 feet.

W. H. Young, of the King Solomon mines, near Etna, reports having reached a ledge last week. He states that a larger force will be put on.

Trinity County.

F. P. Burris, owner of the Bear Tooth group at New River, has purchased an 8-h.p. gasoline engine to be used in operating a new aerial tramway.

Tuolumne County.

The proposed new three-compartment incline shaft at the Rawhide mine, near Sonora, will be sunk 800 ft. north of the old shaft. —— Work on the old shaft at the Hazel Dell mine, northeast of Columbia, will be abandoned, as the low-level crosscut which will be run to tap the vein 600 ft. below the old workings will do away with pumping and hoisting. This crosscut will run about 800 feet.

At present 260 stamps are dropping on the Mother Lode between the Stanislaus and the Tuolumne rivers. These stamps are distributed as follows: The Clio mill, 10 stamps; Shawmut, 100 stamps; Jumper, 20 stamps; Santa Ysabel, 10 stamps; App, 60 stamps; Dutch, 20 stamps; Rawhide, 40 stamps.

The vein in the north and south drifts on the 600-ft. level in the Draper mine near Soulsbyville is reported showing a large vein of good ore.

A. A. Irish of Los Angeles, the principal owner of the Black Hawk mine near Soulsbyville, reports good ore in the shaft.

J. W. Classen, secretary of the Mohican Mining Co., says that the Mohican mine, near Groveland, will resume operations shortly. The company has been doing development and good ore has been found.

Jasper Bros. of Confidence have a contract for the cutting of several thousand cords of wood for the Confidence mine. The mine has been kept unwatered and a few men have been at work on development.

S. A. Knapp has put a force of men at work on the Nelson Gravel mine, at Douglasville, near Columbia.—— W. A. Nevills is preparing to sink a three-compartment shaft to a depth of 2,000 ft. at the north end of the Rawhide mine.——Drifts to a distance of 350 ft. have been driven along a vein at the 200-ft. level in the New Calico mine, near Sonora.——The Golden Gate mining properties, south of Sonora, were sold last week at a commissioner's sale to the M. McCormick Co. for $35,000 to satisfy a judgment held by the purchaser for about $30,000.——Manager Phipps, of the Columbia mine, near Columbia, is in San Francisco making arrangements for the re-opening of the mine.——J. H. Smith has deeded to W. R. Carter all the mineral veins on the property of G. Sivori, at Cherokee gulch, near Sonora.

COLORADO.

Clear Creek County.

Stevens & McGrath have put the workings of the Mendota mine in good shape and the mill is making a larger production than ever. Three cars of zinc concentrates were sent out early last week, and regular weekly shipments are now made.

President William Rogers, of the Santiago Consolidated Mining, Milling & Tunnel Co., is having the mill at Georgetown remodeled and new jigs, tables and another Huntington mill added, which will increase the capacity of the mill to 50 tons per day.

Bloch, Kirby & Co., working the Fort Dodge group in Leavenworth gulch under bond and lease, are drifting on mineral in three lodes, in one of which they have solid ore. The property had lain idle for nine years when the lessees took hold of it, and the first day's work opened up a streak of mineral.——McCluskey & Co. shipped five tons of ore from the Colorado Central mine during the past week, for which they received $827.30. The ore carried 268 oz. silver to the ton. Sifletti & Co. made a shipment of several tons of ore that carried 216 oz. per ton. It is stated that they have two feet of this ore. The Haggart & Co. lease is reported the best in the mine. J. Raymond and F. McCluskey took a lease on the 850 level a few days ago.

Gilpin County.

During the past week the shipments from Central City to outside points included one car of smelting ores from the Concrete and one car of slag to the Globe smelter in Denver, one car of smelting ores to the Argo plant from the Druid Mining Co., and two cars of concentrating ores from the Pozo mine in Nevada gulch to the Newton mill in Idaho Springs.

During the last week of February shipments of smelting and crude ores, tailing and concentrates from the Black Hawk depot to Denver smelters and outside points were 965 tons, making a total for the entire month of 4,785 tons. This was in excess of January about 500 tons.

The Pendleton mine in the Russell district, west of the town, is to be started up by A. A. Johnson, of Denver, under a lease and bond. The main shaft is down 160 ft. and Stroehle & Sons have taken the contract for the installation of a 6x8 friction hoist and a 25-h.p. boiler. A new shaft building will be erected.

The Perrin mine, in the Russell district, has been making shipments to the concentrators at Idaho Springs. The property is being operated under a lease by Jones & Jones, of Russell Gulch.

It is reported that work is to be resumed on the Pueblo lode, on Griffith mountain, owned by Pueblo people.——The Waldorf has made a shipment of 69 tons of concentrates that carried from 40 to 55% lead, 35 oz. silver and a little gold.——Teagarden & Co. have made a shipment from the Sunburst mine of a car each of first

and second-class ore. —— S. Griffin has shipped a wagon load of 244-oz. ore from the Seven-Thirty. It is reported that two additional leases on this property have struck it.

Glanville & Peeck have finished their contract on the Fairfield mine. The property is in Russell district and is owned and operated by Baltimore, Md., people. The main shaft is down 675 ft., and Superintendent Williams has put on two shifts to take out the water.

Stephenson, Hawn and Horning have started their new stamp mill up Moon gulch. The mill is equipped with 10 slow-drop stamps, each weighing 700 lb. The mill was built especially to handle the ores of the Smuggler. A tunnel has been run 250 ft. in the Smuggler, showing a vein which averages 3 ft., and a large amount of free-milling ore has been broken. The free-milling quartz shows $20 per ton.——It is reported the Victoria mine in Lump gulch will resume.——The force at the Perigo on Gambell gulch has been increased, 20 men being at work in the tunnel, all of whom are on lease. During the last run of the Perigo mill 800 tons were treated. A carload of smelting ore shipped by Casagrande & Company is reported to have brought returns of two ounces gold per ton.

Gunnison County.

The new strike recently made on the Golden Islet was of a blind vein encountered in a drift 29 ft. west of the main vein. The ore is four feet wide and assays gave from $8.62 to $47.90. On the foot-wall a streak four inches wide assays $142 per ton. Next to this is an eight-inch streak of 3½% copper ore. Geo. Brant has placed the Islet property. They will drive the cross vein to strike the Montezuma vein which carries high values on the surface. A new hoisting plant will be put in and a double-compartment shaft will be sunk to intersect the Golden Islet vein, Montezuma vein and the blind lead mentioned. It is also the intention to enlarge the mill to at least 100 tons.

Lyons and Black at Pitkin are planning to put a hoist on the Grand Prize. Good ore is still being taken out and regular shipments made.——Several men are employed on the Chloride on development and taking out ore which is being hauled to the mill at Pitkin.——The Cortland property in McIntyre gulch is being operated by leasers, and high-grade ore taken out and shipped.

Lake County.

(Special Correspondence).—Mining here is hampered by lack of facilities for treating ore. The Arkansas valley plant of the A. S. & R. Co. is undergoing improvements to increase capacity, and which will relieve the congestion in the district. There is also talk of several new mills going up, which will help out. There is a great deal of complaint about the mines of the district being obliged to curtail production. Many of the leasers are making good money.——It is reported that the Yak Tunnel Co. has purchased the Diamond property, which is considered valuable ground, and that their tunnel will be extended to that mine. Should the report prove true, it will mean the unwatering of a large territory which at present cannot be worked on account of the large volume of water. To reach the Diamond property the tunnel will be driven over a mile further than the present terminal at the Ibex.——During the coming summer Leadville will see renewed activity.—— The Damascus Mining & Milling Co. is completing a 50-ton mill for handling zinc ores from the A. Y. & Minnie mine, now controlled and operated by the Western Mining Co. The mill will contain six Blake-Morscher electrical separators.

Leadville, March 8.

The Damascus mill, at the foot of Leiter avenue, Leadville, should be running by March 10. Some delay has been experienced owing to slow delivery of machinery. ——Mr. Burdette's mill, on the site of the old Tabor mill, in California gulch, is ready for the machinery. Both of these milling projects are to some extent experimental and anticipate enlargement, if successful. The supply of ores available for both is sufficient for larger plants.

San Juan County.

Two of the four mills that are in course of construction in Silverton district are about to begin operations. ——The Green Mountain mill is ready; also the Great Mogul. They will be shortly followed by the Old Hundred mill, and later by Mr. Kinney's 500-ton Gold Prince mill. The snow has not lately retarded operations, and with good weather work will go on, both above and below the surface. The trails are open and the roads and railways are running on schedule time. The installation of six mills with capacities from 200 to 500 tons per day, will add largely to the year's output. The inadequate shipping facilities make it impossible to transport ores in crude state, and concentration is the sole solution of the problem at present. Millions of dollars' worth of ore is stoped in the various mines of the district ready for reduction.

Summit County.

At Frisco the Admiral Co. has 15 claims. Their air-compressor is run by water power. They have a crosscut tunnel in 1,100 ft. and have three well-defined veins, one of them 20 ft. wide. The entire vein is fair grade ore.——The Excelsior has 500 acres of patented land, an electric plant run by water, a 100-ton mill, several thousand feet of development on a vein from three to six feet wide. Their ore runs from $10 to $100 a ton, principally gold.——The King Solomon Tunnel & Development Co. started many years ago the first crosscut tunnel in the Ten Mile range. They were were the first locations made on Royal mountain. Some of these veins are 20 ft. wide. Three years ago this company was organized to complete this tunnel and for the development of this property, together with the Bonaventure and Buena Vista, the Red Bird and Buffalo placers. The company acquired the only available water power on the Ten Mile river. This ground was patented more than 20 years ago as the Flora placer. East of this the King Solomon owns the Wisconsin placer, a mile of the river bed. This property is equipped with a first-class plant, their compressor now being driven by steam. Ten Mile, at its lowest stage, will generate several thousand horse power. It now costs these companies over $200 per annum per horse power if they use either wood or coal. February 16th the King Solomon was in 650 ft. and advancing at the rate of 100 to 150 ft. per month. They have already cut three paying veins of gold and silver ore.

Teller County.

A rich haul of high-grade ore was made at Victor one day last week by H. C. Brown, of the Mine Owners' Association, two barrels full of ore, some of it extremely rich, being corralled. Brown went to Victor with a spring wagon and secured the ore from the assay shop of George Flochinger, in the basement of the Victor *Times* building. The stuff was found in barrels and sacks and was loaded onto the wagon and taken to Cripple Creek. All efforts to locate the proprietor of the shop failed, and it is believed he received a tip that the officers were after him.

The Ajax Consolidated claim, a fraction belonging to the Ajax company and under lease to Colburn & Prentiss, reports a strike of two feet of two-ounce ore at a depth of 350 ft. A steel gallows-frame has been erected and various other improvements are contemplated at the property.

Because the mill and smelter trust shows an inclination to increase rather than reduce the charges for treating Cripple Creek ore, directors of the Findley mine have decided to partly close down until such time as other arrangements can be made or a mill built by the company. The No. 2 (Shurtloff) shaft will be closed and the No. 1 (Findley) will operate a day shift only. Only such ore as is mined in development and cannot be stored under ground will be shipped. Net proceeds from production at the No. 1 shaft during 1905 were $289,031.58, and from the No. 2 shaft $166,338.98, a total of $455,370.56. The cash surplus Jan. 1, 1906, was $201,015.57. President Carlton says: The condition of the mine is good. The Findley has 70,000 tons of broken ore in the stopes. There is also more ore developed than can be broken in the ensuing year as well as known orebodies upon which development is being conducted.

IDAHO.

(Special Correspondence.)—Robert N. Bell, State Inspector of Mines of Idaho, has completed his annual report and issued it in book form. He estimates the mineral output of the State for 1905 at $19,876,409.89, a large increase over that of the year previous. He recommends an enactment of State and Federal law to give the prospector the right to discover and acquire mining property within the territories owned by corporations, through scrip filings, and in all forest reserves. He also favors restricting mineral rights to vertical boundary lines, and says that better protection should be given to the men working in the mines. He reports 6,000 men steadily employed in mining.

Boise, March 3.

Ada County.

It is reported that 800 lbs. of dynamite and dynamite caps were stolen from various powder houses located in the hills northeast of Boise on the 3rd inst. Governor Gooding had a hundred or more guards thrown over the city, and especially around the penitentiary. These guards were placed because almost all of the men whose names have been mentioned in connection with the prosecution of the officers of the Western Federation of Miners had received threatening letters signed 'Kneebone.' Armed men were also placed around the homes of Governor Gooding, Special Prosecutor James Hawley, W. E. Borah and a number of others. In all there are a half dozen powder magazines situated in the hills. The circumstances surrounding the dynamite thefts are being closely guarded.

Boise County.

John McKay formerly foreman of the Banner mines, near Idaho City, died at his home in that place last week.

Custer County.

The Single Gold Standard Mining & Milling Co. is preparing to put in a 5-stamp mill on its claims near Stanley Basin.

The smelter at the White Knob mines at Mackay will be put in operation in a few days. The White Knob property is now being worked on the leasing system.

Idaho County.

R. Cote is planning to instal a plant on his copper property below Whitebird.——The owners of the Crackerjack mine in the Buffalo Hump district, near Grangeville, report an important strike in the lower tunnel.——The Chlorination plant at the Jumbo mine in the Buffalo Hump district has been closed down, having cleaned up all the concentrates.

Kootenai County.

A 12-drill compressor plant will be installed on the Chicago-London group of mines at Paragon gulch, near Cœur d' Alene. Water power will be used in operating the mines.

Shoshone County.

The fire in the upper workings of the Bunker Hill and Sullivan mine at Wardner is reported to be causing considerable trouble again.——Work will be resumed at the Success mine at Wallace during the present week. ——A re-survey of the Bitter Root Mountain Co.'s mine, near Mullan, is being made in order to determine the relative positions of the ledge and the top level crosscut tunnel.——Work has been started on No. 3 crosscut tunnel at the Black Horse mine, near Murray, to tap a ledge 500 ft. below the No. 2 workings. A 12-drill compressor will be installed.——The Pittsburg Co. after having closed down for a couple of weeks, owing to the break-down in the electric machinery, has practically resumed work in both mine and mill and will be working again full force by the end of the week.——Drifting to the west on No. 2 level in the Oom Paul shaft has been discontinued. Work will now be concentrated on the drift to the east.——Manager McDonald of the Idaho-Los Angeles Co. reports having struck a blind ledge at a depth of 75 ft. in the company's mine on Nine Mile creek, near Wallace.

MICHIGAN.

Houghton County.

Allouez has finished cutting the sixth level plat and is starting the levels. The shaft is now 30 ft. below that plat and the plat itself finished. The lode which swung away from the shaft just before the fifth level plat was cut has again been encountered at the sixth level, where it appears to be swinging back into the shaft again. It contains where tapped the richest copper yet found in the Allouez mine.

The Trimountain mill of the Copper Range Co. is planning to instal crushing rolls which will increase the capacity of the mill about 350 tons daily.

MONTANA.

(Special Correspondence).—All the mining properties that for years have been tied up by injunctions in the Amalgamated-Heinze litigation, have now been released, and in a few weeks will be under operation again. The Amalgamated and Butte Coalition interests have agreed on working lines in the formerly disputed ground, and in some instances, where one or the other party to the old disputes owns but a small interest in joint mining claims that interest has been, or will be, transferred to the majority owner, so that there will be no ownership in common between the Amalgamated and the company formed to succeed to the Heinze interests—the Butte Coalition Co. With the settlement of the litigation almost a third will be added to the mining ground of the Amalgamated and Coalition companies, and it is possible to increase the Butte copper output fully 7,000,000 lb. a month, but it is not yet certain that the increase will be made soon. Eighty suits for injunctions and damages, aggregating nearly $100,000,000, were dismissed in the district court a few days ago, and 23 in the United States court. About half a dozen other suits are still pending in the district court between the former warring companies, but they will be dismissed as soon as a few matters can be arranged with some third parties in the suits.

In addition to the large number of deeds from F. A. Heinze to Thomas F. Cole, transferring all the Heinze and United Copper interests in trust for the Butte Coalition Co., which were recorded a week ago, a number of options from Heinze to Cole have been filed with the county recorder at Butte. The options are for interests in the Belmont mine, Colleen Bawn, Canyon, Homestake, Nora, Chief Joseph, and a number of city lots in the Belmont addition. The options assigned now transfer all of Heinze's Butte interests to the new company, with the exception of the Lexington group.

Mr. Heinze denies the report that he will leave the active management of his mining interests in Montana to others, and make his home in New York. He says he will spend most of his time in Montana and will be active in the reconstructive period of Montana mining.

The Butte Central Copper Mining Co. has been incorporated, with a capitalization of $2,500,000, to develop and operate the Ophir mine, southwest of the city. The Ophir was originally a placer location, but years ago was worked for silver and produced quite a revenue, but in recent years it has not paid operating expenses, although various companies and individuals tried it. S. A. Hall, of Butte, organized the new company, and there are associated with him L. M. Strong and Morgan Strong, of Amsterdam, N. Y. The Ophir was owned by G. E. Blackburn, of Butte, from whom it was purchased by the new company for $250,000. The same men have also incorporated the Butte Green Copper Mining Co. to work a small mine, made up of city lots in the eastern portion of the city. The latter company is capitalized for $500,000.

The Butte & London Co. is making rapid progress in sinking its shaft on the Greendale, being down 100 ft. A lot of machinery for a hoisting plant has arrived.

East of the Butte & London, the Butte Exploration Co. is developing the Six O'Clock group, upon which there is a shaft 300 ft. deep. The old shaft is being unwatered for further sinking. The Butte Exploration has strong financial backing from Boston capitalists, and is in position to thoroughly explore the ground.

As an indication of the activity in mining development and the search for new copper deposits in the Butte district, is the fact that in February 100 new locations were made in the district.

Options are being taken in behalf of the West Butte Mining Co. by Carrol Dolman, who, among other claims, has the Columbia and Merrimac.

Half a dozen new companies are developing properties in the East Butte section, south and east of the Pittsburg & Montana Co.'s properties. The Lewishons, of New York, are interested in the Amazon group, and are doing a lot of exploration work.

The Raven Mining Co. has cut a body of ore in the discovery vein of the Snoozer mine, the body opened being a five-foot streak in a vein 42 ft. in width. The ore averages 7% copper. There are three veins in the Snoozer ground, but the company has been doing most of its work on the most northerly vein, upon which 1000 ft. of drifting has been done on the 1,200 ft. level. From the eastern end of the drift a crosscut has been run south to the discovery vein where the richest ore in the mine has been found. Drifting has been begun on that vein and has proceeded 50 ft. in each direction. Eastward the orebody is widening. The same vein has been cut in the crosscut on the 1,500 ft. level and drifting has commenced on it there.

The East Butte Mining Co.'s leasers are shipping 100 tons of first-class ore daily and the company's concentrator is working 100 tons of second class. The company receives a royalty of 25% which pays for all the extensive improvements being made and leaves a good balance monthly for the treasury. Manager Wall says the three-compartment shaft of the Dutton mine will be completed within six months when that mine will begin shipping ore again and the output of the company will be at least 500 tons a day.

Butte, March 4.

Broadwater County.

Two separate 300-ft. shafts are being put down simultaneously on the General Custer and Myantha leads by the Custer Consolidated Mining Co. of Winston.

Park County.

The 50-ton water-jacket smelter at the Great Republic mines, near Cooke City, is being overhauled and repaired.

Silver Bow County.

Disregarding warnings and declaring he would take a chance, forcing his way on the cage already filled with men at the 1,100-ft. station of the Diamond mine at Butte, James Finley was knocked off the cage before it could be stopped and killed on the 5th inst.

NEVADA.

Churchill County.

J. H. Wilson and others are preparing to put in a hoisting plant and other machinery on their claim near Hazen.

Esmeralda County.

The owners of the Blair property, at Silver Peak, are planning to put in a 100-stamp mill and cyanide plant, either at the mine or at its water supply, which is four miles distant and 1,000 ft. lower than the mine.

Ten leases have been let on the Reno claim at Palmetto near Candelaria.——The Manhattan Red Top Co. is preparing to construct a ditch and pipe-line 14 miles long to furnish water and power for its mines at Manhattan.——James Powell of Salt Lake, it is reported, will erect a stamp mill at Manhattan.——It is definitely announced that Chas. M. Schwab and associates will erect an 80-stamp mill on the Montgomery-Shoshone property at Manhattan.

Humboldt County.

New machinery is now being installed on the Nickel mine near Lovelock.

The Cactus Peak Mining & Milling Co., of which E. Bailey is the executive officer and L. W. Bond, of St. Ives, is vice-president and director, has been developing properties in this section for some time. Mr. Bond says the average value of the sacked ore, which is being shipped, is $100 per ton. The quartz is a solid blue or blackish color, heavily charged with sulphides, carrying gold and silver.

Therin, Stauts and Crumpacker are finding good rock at their mines, near Stone House.

Lincoln County.

J. McIntyre is preparing to sink a shaft on his claim near Los Vegas.

The shaft at the Bowlder mine, near Searchlight, has reached a depth of 172 ft., from which point the drift will be run to the northeast. A hoist has been installed at the shaft. —— G. A. Lane and others have decided to erect an arastra on the Colorado river, near Las Vegas. ——A. Siebert reports having found a four-foot vein of galena 40 miles northwest of Las Vegas, at the north end of the Spring mountain range. —— The owners of the Pope claim at Fay will crosscut from both the 100-ft. and 200-ft. levels.

A discovery of horn silver is reported at Baily's Springs, about 25 miles from Pioche, ore assaying at the grass roots 427 oz. silver. An average assay for width of seven feet went 567 oz. of silver. J. L. Whipple and C. Whipple, cattlemen, with a four-horse team, February 27, were resting on a hillside at lunch. Looking down the valley for their horses, they noticed croppings and broke off a piece, which showed it to contain horn silver. A stampede to the new find is in progress.

Nye County.

R. W. Rathbone has bought the Realty and White Swan claims at Johnnie and has begun sinking 100-ft. shafts on each. —— A bed of molybdenite, north of Johnnie, has been reported. Development began last week. —— West & Boller are opening the old Lynch claim near Johnnie.——The owners of the Quartzite Extension, near Johnnie, have struck the contact at a depth of 40 ft. —— S. S. Patrick, of Goldfield, has purchased seven claims, near Johnnie, from J. Lake, and will open them.

Superintendent O. K. Reed of the Goldreed Mines Co. at Kawich, reports a strike made on the 50-ft. level, an entirely new development and a rich one. The ore is full of free gold, and Mr. Reed thinks that he has the main ore-shoot from which rich ore was secured at the surface. The strike was made in a drift at the 50-ft. level. The shaft is down 200 feet.

J. J. Rutledge, acting for an English syndicate, has purchased the Stand Point claims east of Beatty. He has also bonded other claims in the vicinity of Beatty.

Storey County.

The Butters Co., of Virginia City, is planning to put in a 50-stamp mill on Mill street, with crushing capacity of 200 tons. The pulp from the mill will be flumed to the Butters reduction plant.

The quartz discovered in the Ophir–Brunswick tunnel, near Virginia City, is being explored by a west drift skirting the vein.

NEW MEXICO.

Grant County.

Work will be resumed on shaft No. 1 at the Bonney mine, near Lordsburg. This shaft has been idle since the flood of last fall, which caused it to cave in. Re-timbering is now under way.

The people interested in the mines at Pyramid, near Lordsburg, contemplate building a narrow-gauge railroad from the mine to Lordsburg.——H. R. Fry reports having located a silver-lead mine near the Victoria mines, south of Gage.

Lincoln County.

The Old Abe mine, at White Oaks, which was closed on account of the heavy snows, has been re-opened. A drift is being run along the vein to determine the value of about 1,000 ft. of ground, heretofore unexplored.—— The mill on the South Homestead mine, at White Oaks, is to resume operations.——W. A. McIvers has sold his interests at Jicarilla to the Wisconsin Mining Co. The company has an Elspass plant of 50 tons capacity, which will be put in operation.

Otero County.

The Electric Mining & Milling Co. will instal a large plant at its placer mines, at Jarilla, during the next four months.

Rio Arriba County.

A mill is being erected on the Tampa mine, in the Bromide district, near Tierra Amarilla.

Santa Fe County.

The new mill of the Keystone Co., at Golden, is to be put in operation about April 1.

Socorro County.

The mill on the Enterprise mine, near Mogollon, will begin operations in April.

Taos County.

The American Consolidated Mining Co. is running a tunnel in Long Fork canyon, near Taos, to tap a body of ore.——The Crystobal Copper Mining Co. is uncovering a body of copper ore in its tunnel at a depth of 100 ft. on its property, near Taos.

OREGON.

Baker County.

C. C. Cox, of Baker City, has bought out the other owners of the Oklahoma and Red Bell quartz mine in Goose Creek district, 25 miles east of Baker City.

For the first time in six years, Magnolia's ten stamps, near Sumter, are dropping on ores from the Ajax and Snow Bird veins, principally the latter. In the Snow Bird, after eight years' labor, in September last a strike was made in a shaft 30 feet deep. The ores were treated in neighboring mills, netting from $11 to $20 per ton after mining, milling and transportation charges were deducted. A crosscut tunnel was driven to get beneath the ore-shoot at an added depth of 100 feet. Failing to find the orebody, the crosscut was continued and discovered a 12-ft. vein of good ore.

Douglas County.

The owners of the Levens Ledge mine, near Canyonville, have begun driving a tunnel.

The Crystal Consolidated Mining Co. will resume operations at Bohemia.——The stockholders of the Sterling Mining Co. have decided to put in another 10-stamp mill at its mine, near Roseburg.

Jackson County.

A 60-h.p. gasoline air compressor and power drills have been installed at the Blue Ledge copper mines at Applegate, and a series of new tunnels has been begun to cut the deposit at a lower level. The new owners have filed claims on 8,500 in. of water.

Josephine County.

The Golden Drift Mining Co. has temporarily shut down its mine near Grants Pass. Machinery has been ordered for a new steam dredge and for two 400-h.p. turbines. The latter will be installed immediately and another complete unit pump will be added early in the summer.——Electric power has been attached to the Granite Hill 20-stamp mill and hoisting plant at Granite Hill.——The mine of the Michigan Mining & Milling Co. at Murphy will be started up soon.——A. C. Hoefer, manager of the Mount Pitt Hydraulic-Quartz Mining & Milling Co., has purchased air-compressor drills and a stamp mill in San Francisco for the company's mine near Merlin.

Lane County.

The Treasure mine at Blue River has closed down and will not be re-opened until spring.

Union County.

The Oregon Copper Mining & Power Co. is preparing to develop 12 claims six miles from North Powder.

TEXAS.

El Paso County.

Three new roasters are being installed at the smelter of the American Smelting & Refining Co. at El Paso to replace 12 reverberatory furnaces hitherto employed.

UTAH.

Grand County.

The Crescent Peak Gold Mining Co. has let a contract for the sinking of a shaft at Crescent. It is planned to search the lowest level ever attained in that district.

Juab County.

The shaft of the Tetro mine, near Eureka, which has reached a depth of 300 ft., will be continued to the 500-ft. level before crosscutting is undertaken.——Nearly all of the machinery of the Godiva mill at Eureka is in place, except the electric motor. The mill will be started about March 15.——Superintendent E. Levin, of the McKinley mine at Eureka, reports that the tunnel is in 900 ft. and that a crosscut running east has been begun.

C. E. Johnson has begun sinking a shaft on his claim in the Clifton district, 40 miles northwest of Fish Springs in this county. It is reported that galena has been found at a depth of 100 feet.

The re-timbering of 350 ft. of the shaft between the 300 and 700-ft. levels at the Grand Central mine has been completed and the usual force put to work. Preparations are being made to sink the main working shaft several hundred feet, but this will not interfere with taking out ore. A donkey-engine will be installed on the 1,300-ft. level and used in sinking the shaft.

Piute County.

The Revenue Deep Tunnel & Mining Co. has let a contract for the extension of a tunnel on the Copper Belt ground on the company's property, near Marysvale.—— The owners of the Bully Boy property in Bullion canyon, near Marysvale, have been crosscutting to the west in order to find the vein.

Tooele County.

Peter Haack, of Los Angeles, Cal., is reported to have purchased the interests of Willard F. Snyder in the Honerine Mining Co. at Stockton for $314,000.

WASHINGTON.

Ferry County.

The owners of the Pearl mine, near Republic, are putting in a tramway.——A long tunnel at the Oversight mine, near Republic, is being continued. The ledge has not yet been crosscut, and it is given out that shipping will not begin until about May 1.

Okanogan County.

(Special Correspondence.)—F. M. Dallam says there is more development in Okanogan county at present than for years, and the prospect for the country is better than ever before. The Victoria, Vancouver & Eastern Railroad is building into the mines.

The Copper World Extension on the summit of Palmer mountain is sinking a 500-ft. shaft. At a depth of 200 ft. they ran a crosscut and found 40 ft. of high-grade copper ore. The new railroad will run within 10 miles of this property. This is the most important strike made this winter. The Grand View on Mt. Chapaca, in the same district, is nearer the railroad. It is a gold mine. The company has completed a 20-stamp mill and wire tram from mine to mill. One span of this tram is 1200 ft. The company has an electric plant which furnishes power for all purposes.—— The Ruby, which is a high-grade silver proposition, made a recent strike in the 900-ft. tunnel.——During the winter the Q. S., a copper mine situated between the Loomis and Conconully, has struck the ledge at a distance of 1,200 ft. in the tunnel.

Spokane, March 3.

The Riblet Tramway Co., of St. Louis, has completed a 4,300 ft. aerial tramway for the Grand View Gold Mining Co., extending from the company's mine to its 20-stamp mill on Palmer Lake, near Loomis.

The 750-h. p. electric plant at the Palmer mountain tunnel, near Loomis, is practically completed, reports John Boyd, manager of the company. It cost $51,000. The turbine wheel operates under a head of 370 ft. The water is taken from Toat's Coulee creek through a 4 by 2-ft. flume 5,400 ft. long.

FOREIGN.

BRITISH COLUMBIA.

Burrard District.

The Rosella Mining & Development Co. has completed its plant at Telegraph creek and will commence operations about June 1.——The Prospecting, Mining & Development Co., of Seattle, has secured dredging rights at Telegraph creek, and is now putting a dredge at China bar.

Comox-Atlin District.

Dr. Young, member of the British Columbia parliament for Atlin, has introduced a bill to amend the placer mining act so that claim owners may acquire claims 500 ft. long along the creeks and 500 ft. on either side to the hillsides.

G.W. Elliott, representing Seattle and Chicago people, has made final payment on the Bonanza group of galena claims at Bowen island. This group includes eight claims on the west slope of Bowen island, running down to tidewater.——E. B. MacFarlane and others of Portland, Or., are preparing to begin development work on the Stewart claims, near Port Simpson. A steam or electric tram will be put in.

Lardeau District.

The owners of the Del Rey mine, at Camborne, are opening a vein of free gold quartz in the west drift. The various smelters in the Kootenay district have made a reduction of 20% in charges for the treatment of lead ores.

Victoria District.

An English syndicate has purchased five mineral claims near Parson's bridge, formerly owned by J. Berryman of the Excelsior Hotel, Victoria. A diamond-drill, costing in the neighborhood of $4,000, will be installed.

Yale and Cariboo District.

The steel hoods from the furnaces at the Granby smelter at Grand Forks, are being replaced by brick. A new 10-inch steel pipe is being laid from the pump-house to the furnaces and two tramways are being laid in the furnace and converter building.——New machinery will be installed at the Sullivan smelter at Marysville.——R. P. Inglis, of Montreal, has bought the Golden Sovereign claims at Aspen Grove from McConnell & Millar.

The owners of the Helen mine at Greenwood have purchased the Strathmore mine, in the same section.—— The Granby smelter, near Phœnix, reports having made a record-breaking run of 2,850 tons of ore one day last week.——About 500 ft. of diamond-drill work has been done on the Betts & Hesperus group of mines, near Phœnix.——Excavating for extensive enlargements at the British Columbia Copper Co.'s smelter at Greenwood has been started.

MEXICO.

Official notice has been sent out by the Mexican Secretary of State that President Diaz had revoked the recent order forbidding foreigners to locate mines in the State of Sonora, Mex., and in Lower California.

A mining convention will be held in Mexico City on May 1 for the purpose of establishing a permanent chamber of mines at Mexico.

Chihuahua.

The Monteverde Mining Co. has secured water rights in the Monteverde river, near Chihuahua.

Work has been resumed on the Culbera mine, near Etzatlan. A tunnel will be driven toward the vein.

Durango.

Large reduction works will be installed in the Guadalajara mine at Inde. The plant will include a 100-ton wet crushing cyanide plant electrically driven.

Guanajuato.

Ernest du Bois, manager of the Mexico Gold & Silver Recovery Co., has taken legal action to close the experimental cyanide plant of the Guanajuato Reduction & Mines Co., at Bustos, claiming that the latter company is using MacArthur-Forrest cyanide process without authorization.

Hermosillo.

The San Rafael Copper Mining Co. is to begin development on its holdings, 16 miles from Hermosillo.

Sonora.

The Alamos Mining Co. is to erect a smelter on its property in the Alamos district, below Guaymas.——A leaching plant is to be put in at the Roy mine in the Alamos district.——O. T. Clark, of the Silver Leaf Mining & Milling Co., states that extensive development will begin on the company's property, near Nacozari.

Personal.

EDGAR RICKARD is in New York.

CHARLES BUTTERS is at Copala, Mexico.

C. W. PURINGTON is at Phœnix, Arizona.

JOHN HAYS HAMMOND is at Salt Lake City.

WALTER P. JENNEY is at Tonopah, Nevada.

JAMES W. NEILL is on his way to New York.

E. E. EDMONDS, of Goldfield, is in San Francisco.

MARK L. REQUA has returned from Ely, Nevada.

DANIEL GUGGENHEIM is expected in San Francisco.

J. D. HARDIN has returned to Deadwood from the East.

J. A. SHINN has returned to Leadville from New York.

BEN. B. LAWRENCE has returned to New York from Cuba.

GERALD M. BROWNE is at Kalgoorlie, Western Australia.

RICHARD PEARCE is on his way from Denver to England.

HOMER WILSON has returned to San Francisco from New York.

CHARLES MCHUGH has returned to Deadwood from New York.

THOS. H. LEGGETT is on his way to London, by way of New York.

JOHN Y. COLE, formerly at Rossland, is now at Cobalt, Ontario.

THOS. H. MEANS, of the Reclamation Service, is at the St. Francis.

F. H. MINARD is in Arizona. He expects to go to London shortly.

J. F. HALLORAN has returned to San Francisco, after a holiday in Tahiti.

FRANK ENSENSPERGER is manager of the Union Hill mine, near Grass Valley.

ROBERT GRAHAM has returned to his mines at Huepec, Mexico, from the East.

W. H. TREWARTHA-JAMES is engaged in advisory work in Western Australia.

L. C. CHURCH is visiting San Francisco and returns this week to Joplin, Missouri.

A. O. CAUTLEY, of London, has been negotiating for mines at Guanajuato, Mexico.

M. B. SPAULDING is general manager of the Real del Monte mines, at Pachuca, Mexico.

R. E. TAYLOR, of Tonopah, and J. N. PEYTON, of Spokane, are at the Palace Hotel.

H. KILBURN SCOTT, who has been in Brazil reporting on mining properties, is in London.

PHILIP L. FOSTER visited San Francisco on his return from El Oro, Mexico, to New York.

PERCY B. MCCOY, of Kempton & McCoy, has returned to New York from Nicaragua.

A. CHESTER BEATTY is examining the Nevada Consolidated copper mines, at Ely, Nevada.

FREDERICK H. HATCH is now with Lewis & Marks, at 28 Bishopsgate Street (Within), London.

A. STEWART MAY has returned from Mexico, and has opened an office at 82 Wall St., New York.

EDGAR NEWHOUSE has been appointed managing director of the new Balaklala Co., near Kennett.

JOHN BOYD, manager of the Palmer Mountain Tunnel Co., near Loomis, Wash., has gone to New York.

JAS. W. MALCOLMSON, soon after his return from Oaxaca, has left El Paso to go to Guanajuato, Mexico.

C. HOWARD, of San Francisco, has been making an examination of the Lecompton mine, near Nevada City.

JUAN F. BRANDES of Denver is on his way to Chihuahua, Mexico. He is expected in San Francisco within a month.

W. E. SHARP of Florence, Ariz., is in San Francisco to purchase machinery for his mining interest, near Florence.

H. L. PAYNE, of the Wade & Wade Co., is in southeastern California examining gold mines for local capitalists.

JOHN GRAY has returned from California to the general management of the Wasp No. 2 mine, near Lead City, South Dakota.

GEORGE A. TWEEDY has returned to Los Angeles from Mazatlan, Mexico, where he is consulting engineer to the Minas del Tajo.

OSCAR ROHN, formerly of Michigan, has taken the management of the property of the Pittsburg & Montana Copper Co. at Butte.

L. W. FELT of Lake City has succeeded E. W. Walters as manager of the Green Mountain Mining & Milling Co. at Silverton, Colo.

R. B. NICKERSON, lately superintendent of the Confidence mine, in Tuolumne county, has taken up residence at Berkeley, California.

JOHN C. BRENNON, manager of the Ajuchitlan Mining Co., in Queretaro, has joined in partnership with ALVIN B. CARPENTER, at Mexico City.

METALS.

SILVER.—Per oz., Troy: New York, (by wire), bar silver, 64½c. per fine ounce; San Francisco, 64½c.; London, 29⅝d. (standard ounce, 925 fine); Mexican dollars, 51@52c., San Francisco; 49½c., New York.

COPPER.—New York (by wire, average for week ending March 8), Lake, $18.50@18.62; Electrolytic, 18.20@18.37c.; Casting, 17.87@18.12c. per pound. Mill copper plates, $21; bars, 21@24c. London: £79 15s. spot per ton.

LEAD.—New York (by wire, average for week ending March 8), $5.35 per 100 lb; San Francisco, pig, 5.70@6.60c. per lb.; pipe 8@8½c.; sheet, 9@9½c.; London: £15 10s. ℔ long ton.

SPELTER.—New York (by wire, average for week ending March 8), $6.15@6.25 ℔ 100 lb.; London, £24 7s. 6d. ℔ ton; San Francisco, ton lots, 7c.; 100-lb lots, 7¼c.

TIN.—New York, pig, $35.62½@35.97½; bar tin, ℔ lb., 42½c.; pig, 39c. London, £163 2s. 6d.

PLATINUM.—San Francisco, crude, $18.50 ℔ oz.; New York, ingot, nominal, $20@25 ℔ Troy oz. Platinum ware, 75@$1.00 ℔ gram.

QUICKSILVER.—New York, $40.00@$41.50, large lots; London, £7 7s 6d.; San Francisco, local, $39.00 ℔ flask of 75 lbs.

NICKEL.—New York, 48@60c ℔ lb.; ton lots, 40@47c.

ZINC.—Metallic, chemically pure, ℔ lb., 50c.; dust, ℔ lb., 10c.; sulphate, ℔ lb., 4c.

BABBITT METAL.—San Francisco, No. 1, 10½c.; No. 2, 8c.; No. 3, 7½c.; extra, 17½c.; genuine, 32½c.; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 23.50c; San Francisco, Plumbers', 100-lb. lots 19.75c.

ALUMINUM.—No. 1, 99%, small lots, 35@38c. ℔ lb.; 100 lbs., 35c.; 1000 lbs., 34c.; ton lots and over, 33c., Pittsburg. No. 2, 90%, small lots, 34c.; ton lots and over, 31c, Pittsburg.

GENERAL SUPPLIES.

ANTIMONY.—New York, per quality, 16c@17c; San Francisco, 1000-lb. lots, 16c; 300@500-lbs. 12c, 100-lb. lbs. 12c; 100-lbs lots, 13c.

BONE ASH.—Extra No. 1, 6c ℔ lb; No. 1, 5c½.

BORAX.—Concentrated, 9½c ℔ lb; powdered, 10c; fused, 25c; crystal, refined, 8c.

CANDLES.—Standard Oil Co.—Electric light, 16 oz., 11c; 14 oz., 9¾c; 12 oz., 8¾c; 14 oz., 7¾c; Hotel, 12 oz., 9c; Granite (mining), 16 oz., 11¼@11½c; 14 oz., 10@10½c; 12 oz., 9¼@9½c; 10 oz., 8½c; Paraffines, White, 1s, 2s, 4s, 6s, 10½c; 12s, 11c; colored, 1c higher; Radiant Paraffines, 4s, 6s, 14 oz., 9¼@9¾c; 10 oz., 7¾c.

CAPS.—3x, $5.50@6 per 1000; 4x, $6.50@7; 5x, $8@8.50; Lion, $9@9.50, in lots not less than 1000.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 23@24c ℔ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 3@3½c ℔ lb.; caustic soda, in drums, 3@3½c ℔ lb.; Cal. s. soda, bbls., $1.10@1.20 ℔ 100 lbs.; sks., 90c@$1.00; chlorate of potash, 12@13c; nitrate of potash, 6½@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2¼@2½c; flour sulphur, French, 2¾@—c; alum, $2.00@2.25; California refined, 1¾@2c; sulphide of iron, 8c ℔ lb.; copper sulphate, 6¼@7c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66% B, 1¾@2c ℔ lb.; nitric acid, carboys, 8c ℔ lb.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1**, 50%, carload lots, 11¾c; less than one ton, 13¾c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2**, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

COAL.—San Francisco, coast, yard prices to dealers: Wellington, $7.50; Seattle, $6.50; Coos Bay, $5.50; Cargo lot, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $14.00; Cannel, $8.50; Rock Springs, $8.50, long ton; Colorado Anthracite, $14.00. Coke, $11.50 per ton in bulk, $13.00 in sacks; Sunnyside, $8.50, long ton.

Trade Treatises.

Allis-Chalmers Co. have issued Catalogue No. 129, descriptive of machinery for cement making.

Commercial Paragraphs.

THE Champion Copper Co., of Houghton, Mich., recently purchased a standard 20-ft. Hancock jig from the Allis-Chalmers Co., Milwaukee.

THE Alaska Treadwell Gold Mining Co., of Treadwell, Alaska, has ordered a 20x48-in. double-drum, direct-acting hoisting engine, built by the Allis-Chalmers Co., Milwaukee.

THE assay firm of Wade & Wade, who have been for over 18 years in business in Los Angeles, have recently re-organized and have taken in as a partner H. L. Payne, formerly of Cleveland, O. Mr. Payne will devote his time to mine reporting and to general chemical work.

THE Colorado Iron Works Co. of Denver, Colo., lately shipped two impact screens to the Annie Laurie mill at Kimberly, Utah, and one to the Compania mine, Chihuahua, Mexico; two forehearths and two vertical-shaft skips to the St. Joe Lead Co., Bonne Terre, Mo., and two sample grinders to the Nevada-Goldfield Reduction Co., Goldfield, Nevada.

Messrs. Harron, Rickard & McCone report the sale of a large cross-compound, two-stage, condensing Corliss compressor, of the Ingersoll-Rand make, to the United Verde mine, at Jerome, Arizona. The machine is of special interest on account of its size. It has steam cylinders 28 and 52 in. diam., air cylinders 44½ and 26½ in. diam., all 48-in. stroke. At 75 r.p.m. the piston displacement is 6,060 cu. ft. free air per minute; the compressor complete weighs about 300,000 lb. The machine is to operate at 5,500 ft. altitude and develops about 940 h.p. The air pressure is to be 100 pounds.

THE Power & Mining Machinery Co., of Cudahy, Wisconsin, has closed a contract for a complete rock crushing plant to be erected for the Little Falls Stone Co., Little Falls, New York. The main crusher is a No. 10 McCully, the largest machine of its kind ever designed or built. Its weight will be nearly 200,000 lb., and its capacity, under favorable conditions, 700 tons of crushed stone per hour. Among the principal auxiliary machinery to be installed in this plant are four No. 6 McCully crushers for crushing rejections from the No. 10 crusher; one No. 10 elevator 60 ft. long; one No. 9 elevator 67 ft. long; two 60 in. by 15 ft. rejection screens, and two 60 in. by 35 ft. sizing screens of special design. The product from this plant will be used for ballast, railroad and concrete work. All of the dust or fine material from the crushing is to be used for making cement bricks, the manufacture of which will be carried on in a near-by plant owned and operated by the same company. H. A. Shaper, formerly manager of the Mohawk Valley Stone Co., is the general manager of this new enterprise.

THE American Institute of Mining Engineers, which for the two days preceding had been in annual session at Bethlehem, Pa., was on February 24 entertained by the Ingersoll-Rand Co. at their works at Phillipsburg, N. J. A special train brought the visitors—165 in number—direct to the grounds; they were received by President W. L. Saunders of the company, assisted by members of the sales and engineering departments. The party was at once photographed on the steps of the office building, and each guest was presented with a leaflet, showing a plan of the works, in black, with the route of the visitors through the shops, in red. In addition, the leaflet contained tabulated engineering data of the shop arrangement, equipment and capacity, together with a record of the company's machine production since its foundation in 1871. The guests, divided into parties, were piloted over the specified route through the shops, inspecting the many classes of machinery built there, both in construction and in operation. After a morning spent in this manner, the visitors were conducted to the dining-room on the third floor of the office building, where a luncheon was served. After an hour of fellowship and good cheer, a second photograph was taken and the company was called to order by Mr. De Saules, acting chairman of the entertainment committee. After a few happy remarks, the chairman called upon President Saunders of the Ingersoll-Rand Co., who responded, calling attention, among other things, to the fact that the Institute was not up-to-date, in that it still clung to the hand-hammers on its emblematic seal, which should properly be replaced by a machine-drill as more typical of modern engineering progress. Mr. Jasper Rand, vice-president of the company, then made a few remarks upon the close and intimate relations in the new company which had taken the place of the keen rivalry between the former Ingersoll and Rand companies. The next speaker was Mr. Edmund C. Pechin, one of the charter members of the Institute, who gave some historical reminiscences. He was followed by Dr. R. W. Raymond, secretary of the Institute. The informal program closed with a song by Prof. Franklin of Lehigh University, which told of the intimate relations of 'Sandy and his mule' in the days before machinery was introduced in the coal mine. The party then adjourned, returning by their special train.

Obituary.

M. J. FERGUSON, mining engineer, was instantly killed on the 4th inst., while surveying in the Yampa mine at Bingham, Utah.

FRANK CAREY, a mine operator of Copper river and Nome, Alaska, recently jumped from the steamer *Excelsior* near Yakutat, and was drowned.

JUDGE C. V. GOTTSCHALK, of San Andreas, Cal., died by his own hand on Friday the 2d inst. For years he had been a prominent figure in the California bar and had been identified with many important mining suits. He was respected by all parties to these suits because of his clearheadedness and eminent fairness in deciding difficult points at law. He was 79 years of age and in recent years had become enfeebled, and had almost lost his eyesight.

Standard Books

EDITORIAL.

PRESIDENT DIAZ has revoked the recent order forbidding foreigners to locate mining claims in the State of Sonora and in Lower California. It was an order which brought discredit to the Mexican Government and we are glad to announce its revocation.

THE final report covering the liquidation of the Whitaker Wright companies, at London, exhibits a tremendous loss to the British public. The assets, which were estimated to produce $14,505,100, realized $2,575,970. To realize this, cost over $1,500,000. The unsecured creditors, whose claims aggregated $12,958,375, received $921,585. There was nothing to return to the shareholders. Liquidation is evidently a costly luxury and the results of this particular one will confirm the average eupeptic citizen's notion that liquidation resembles the metallurgical process of liquation.

RUSSIAN bureaucracy is again inviting foreign capital to exploit its territory in Asia. Northern Manchuria is described as a region affording a good field for American enterprise and eastern Siberia is suggested as ready for the American explorer. We trust that no one will be misled by any specious promises from a quarter so untrustworthy. It is easy to invest money in the Czar's dominions, but it is difficult to get it out. A country ruled by an irresponsible bureaucracy is a poor place for mining operations; even a South American republic is better, because it can be called to order.

WHEN Walter Scott, the alleged "cowboy miner of Death Valley," flashed his money all over the continent and hired a special train to beat the record from Los Angeles to Chicago, in order to proceed to New York and spend his swag on the Bowery like a drunken sailor, it was supposed that he might be preparing to sell a mine. People sometimes do funny things when they sell mines. The stories of prospecting in the desert, of a mysterious hole whence came golden treasure, of 'gun play' in the wilds, and the dramatic efforts of other adventurers to find the source of his wealth, seemed likely precursors to a flotation either in Wall street or State street. But the purpose is now disclosed, and it is not without its cynical humor. Scotty has gone on the stage!

Guggenheim Activity.

It is understood that Messrs. J. P. Morgan and Daniel Guggenheim, representing two important reservoirs of money, have entered into a joint agreement to build a railroad about 400 miles long, from Valdez, on the coast of Alaska, to Eagle City, on the Yukon, traversing the Tanana region and tapping the Copper River country, which is considered one of the richest portions of Alaska. They have an option on the Bonanza, Nikolai and Elliott creek mines in the Copper River district and they have arranged to secure the control of Henry Bratnober's interests in other copper claims in the Tanana district. Moreover, the cohorts of the Guggenheims have closed around the Nevada Consolidated copper mines at Ely, Nevada. The control of this enormous deposit of low-grade copper ore has passed to them and they have acquired the Giroux property in the same locality. These deposits were estimated nine months ago to contain six million tons of 2½ per cent copper ore, but recent exploratory work has shown even this unusual tonnage to be only a part of an immense mass of sulphide ore disseminated in rhyolite porphyry. Again, the American Smelters Securities Corporation has quietly secured the Balaklala mine in Shasta county and their engineers are making a preliminary investigation of Thomas W. Lawson's Trinity mine. All these purchases and industrial activities foreshadow the growth of an important copper mining and smelting industry on this Coast, of dimensions far exceeding even the present noteworthy operations in the red metal. The output of the copper mines in our own State, in Nevada and in Alaska will be tributary to the new smelter which will be built close to San Francisco, as stated in these columns last week. The extreme western part of North America is going to produce a great deal of copper, and we welcome the increased importance as a technical and industrial center which these events will give to the City by the Golden Gate; nevertheless, we do regret the passing of mines well managed by local men into the hands of the big financiers who are objectionable only because of the tendency they exhibit to form big consolidations hurtful to legitimate competition and calculated to stifle the individuality of professional men.

CONTRIBUTIONS to the discussion on 'The Best Shape for a Shaft' continue to arrive, and it is evident that the subject is one of practical interest. Mr. Thomas H. Leggett is an authority, having been engineer to some of the big undertakings on the Rand, while Mr. Robert Peele, professor of mining in the Columbia School of Mines, has a close acquaintance with Western mining such as gives his views particular value. Mr. Theodore E. Schwarz has had charge of some of the largest mines in Colorado. Next week we shall publish contributions on this subject from Messrs. John A. Church, R. V. Norris and other experienced engineers.

THE coal-mine disaster in the Pas de Calais region, in northern France, is of unusual magnitude, for the loss amounts to 1,212 lives. This catastrophe is imputed to the coal-miner's great enemy, fire damp, the explosion at Courrieres having been followed by such destruction to the mine-openings as to render the work of rescue impossible. We are able to publish a timely article by Mr. Donald F. Campbell, who visited the locality recently. The photographs suggest the conditions under which the miners work. It remains but to direct attention to the one compensating feature of the calamity, and that is the heroic assistance given by Germans, from the Westphalian coalfield, who came to the aid of the French officials at Courrieres.

AT BISBEE, the mine and smelter workmen met on March 5 to decide whether they should form a union to co-operate with the Western Federation of Miners, and it is worthy of record that when the poll was taken, there were 2,228 ballots against and 428 for the proposal. The vote is stated to represent the full force of the local organization. While the matter may not be finally settled, the vote is significant. There are many mining corporations that might well take a hint from the experience of the Copper Queen and Calumet & Arizona companies and model the treatment of their employees accordingly. The fact is generally appreciated at Bisbee that nothing except the upright dealings of the officials controlling the operations of these companies is responsible for the attitude of local labor to the outside union. "Man's inhumanity to man" is at the bottom of half the labor disturbances, and there is no way better calculated to secure efficient work and undisturbed continuity of operations than methods based on fair dealing and humane consideration, on both sides

Events in Idaho.

Boise City, the capital of Idaho, is the scene of important events at this time, for the preliminary proceedings leading from the arrest of a number of well-known agitators is attracting the attention of mining communities throughout the country. The idea prevails among laboring men and, more particularly, the members of various labor unions, that the men now held in the county jail at Caldwell are being hounded by the agents of mine-owners and others keenly desirous of stamping out the Western Federation of Miners. For this reason the Governor of Idaho is receiving letters of protest frem all over the country, and at the same time the labor organizations are contributing generously toward the expense of retaining able counsel for the defense. However, it is also a fact that those who, as owners of mines, managers and engineers, have suffered from the tyranny of the worst form of trades-unionism during the stormy days when the Cœur d'Alene, Cripple Creek and Telluride were synonyms for brutalities disgraceful to any civilized government, are fearful that the men arrested for the murder of ex-Governor Steunenberg and other assassinations will not be successfully prosecuted because so much pressure, political and financial, is being brought to bear upon the local authorities at Boise. We have received letters from individuals taking an interest in both sides of the case, and expressing the contrary opinions just outlined.

Our position as spokesman for the serious mining men, not capitalists alone nor workmen alone, but all who, whether by brains, muscle or money, work toward the development of the mineral resources of these United States first, and of other countries afterward—the position we take is, that justice must

be done and the Law, too long outraged, must be vindicated, not in the spirit of a capitalist vendetta against labor or labor's feud against capital, but in justification of popular government and as the assertion of the community to be free from the tyranny of any lawless organization, led by no matter whom, whether mine-owner or mine-worker. It is against the best interests of those who are interested in mines, whether as investors or managers, to take any action that will lead to the conviction of an innocent man, and it is equally hurtful to the good intent of trades-unionism to defend a criminal. Therefore it is fortunate that at this time the Governor of Idaho, Frank R. Gooding, should have spoken so clearly as to his position in the matter. It was in response to a letter from a committee of the Central Labor Union of Evansville, Indiana, which expressed regret at the idea that "prosecution of the men is in pursuance of a conspiracy" among mine operators to destroy the Western Federation of Miners. The Governor explained that their arrest was based on the voluntary confession of two suspects who had given information, so precise and so revolting, that he, the Governor, was compelled by his oath of office and by his feelings as a man and an executive to ask for the arrest and extradition (from the State of Colorado) of the men implicated. He concludes his letter to the committee at Evansville in these words: "If the stories are true, you and the members of your union will certainly agree with me that no punishment under the law is too severe to be meted out to the guilty men. Their guilt or their innocence cannot be said to have any bearing upon the rights or privileges of union labor. Labor organizations are vitally interested in this case. If the men now accused are guilty of murder, they should be condemned by all labor organizations in the world. If they are innocent the State of Idaho will do its duty in righting the wrong done them." These are manly words and they betoken a man who is safe and sane. It is fortunate that the direction of the prosecution is largely in the hands of so good a citizen.

Counterfeit Processes.

The vendor of patent medicines never applies to the reputable physician. He may be a charlatan, but at least he has sense. And by the same token, the man with a fake process never takes his wares to the intelligent mining engineer or metallurgist. His chosen field is the raw, young camp where lucky prospectors and promoters have suddenly blossomed out into mine-owners, and are in a ripe condition to be humbugged. Unfortunately, the poor prospector who wakes up and finds himself rich is not always the good friend of science. If not in overt antagonism to the great fund of scientific knowledge which has been accumulating since long before he was born, he may be simply indifferent to it, for neither by training nor environment is he the type of man who studies and investigates. Moreover, though shrewd and common-sensible in most respects, he is imbued with the time-honored fallacy that engineers and other professional men are impractical; and his partners and associates, abetted by the wily man with the 'new process,' advise him to shun the dangerous professional person whom they have ingloriously branded as an *expert!* "No experts for me!" says the prospector-manager; "*I* don't want to make any mistakes." And the man with the new process—be it a patent, revolving hot-air amalgamator, or an electro-thermal cyanide agitator—is at once installed as guide, philosopher and friend!

The prospector-manager is generally sure of his own views, because the 'new process' man so cordially agrees with him in the premises. These premises are: (1) that metallurgists, so-called, are simply floundering in darkness and ignorance; (2) that all known and well-established processes are empirical makeshifts reluctantly adopted by mining companies because they can find nothing better; (3) that professional men must be avoided as so many harpies on the lookout for big fees and easy jobs.

A journal in one of our new camps recently stated, in referring to a recent mill installation, that the process to be used was a secret; that it was something like the cyanide process and yet not quite like it, the distinguishing point of difference being that "no pans or basins were to be used!" Now could anything be more deplorable than the cyanide process bereft of pans and basins?

It is evident that the 'new process' man is abroad in the land. He should be carefully watched, and the mine-manager with a problem of ore-treatment to solve should be able to distinguish between this plausible individual and the intelligent investigator who quietly works along legitimate lines of improvement in applied metallurgy. The man who enriches science with a new and valuable idea, a labor-saving appliance, or any improvement that enhances the efficiency of a known process is pretty sure of hearty and instant recognition. These remarks are manifestly not directed against him, but against that misguided enthusiast, half-promoter, half charlatan, who, with the little knowledge which is so dangerous a thing, and with a sublime impudence and cocksuredness, goes about luring the credulous into an adoption of his untried schemes.

An Important Decision.

In deciding the case of the Grand Central against the Mammoth Mining Company, the Supreme Court of Utah has given us a valuable treatise on the law of mines. Not since Justice Field wrote the decision in the Eureka-Richmond case have we had anything comparable to it, especially in clearness of statement, in fulness and breadth of treatment and in the vigorous way each issue is exhaustively discussed and conclusively decided. It is a decision that will be welcomed by the mining community generally, and that anyone with a fair knowledge of mines can read and understand, so plain and simple is the language. The Grand Central won every point by a masterly defence—cleverly conceived and ably sustained. Best of all, no one, unless blinded by interest, can read this decision and not feel that the rightful owner of the ore won. We publish a lengthy abstract of the decision on another page.

It is the custom to disparage the United States mining law; unfortunately, it has come to stay, and it will be well to realize the fact. Perhaps in time it may be possible to amend the law in certain particulars, but experience demonstrates that every attempt to substitute any other is doomed to failure; without assigning any reason, the general run of people interested in mines have again and again shown that they desire no change in the law, however manifest it may be to careful students of the problem that the law is radically defective. In any event an amended law could only be applied in new mining districts. It is a matter of congratulation that the courts, especially during the last few years, have displayed a steadfast intent to construe and build up the law, by a series of able decisions, which in time will define the rights of the miner under circumstances commonly arising. This constructive policy is illuminated by a number of decisions on apex rights, leading up to the several decrees of the Court of Appeals in the St. Louis-Montana case, and also the late decision in the Stemwinder-Bunker Hill suits, adjudicating interfering extra-lateral rights, and upholding the principle that the position of the 'wall' of a lode is a commercial one; as was also decided in the case under review. The Supreme Court of Utah does not lay bare the imperfections of the mining law, but goes to work to ascertain the facts, to interpret the law, and to determine the rights of the parties thereunder; in short, the Court takes the law as it exists, and, in settling the property rights of the litigants, leaves us with a better and broader understanding of the meaning of the Act of 1872. This decision is pre-eminently constructive; we have had decisions which complicated, without intending to do so, the interpretation of the Act; this one simplifies it. It is certain to be quoted at great length in the judication of many issues arising under the mining law; particularly questions relating to 'discovery' and 'apex,' and to the right to follow a vein on the dip; questions involving the determination of what constitutes a 'vein or lode,' and what are its boundaries. So far-reaching may it prove, in application to legal conflicts constantly arising, that many an attorney, wrestling with knotty problems of this kind, in the widely scattered mining camps of the West, may truly say to the Grand Central, in the words of Rosalind to Orlando, "Sir, you have wrestled well, and overthrown more than your enemies."

By the Way.

The volcanic region of America extends along its great mountain backbone from Patagonia to Alaska. In a recent issue of the *Evening Post*, New York, Mr. F. S. Dillenbaugh makes some interesting observations concerning the volcanic fires of the frozen North. He says:

In Alaska we find one of the greatest centers of present volcanic energy, a belt of country 1,600 miles long by 40 wide, adorned by a series of noble peaks beginning with Mt. Wrangel above the head of Cook Inlet and extending throughout the length of the Peninsula and the Aleutian chain of islands. No less than 25 of these islands possess volcanic activity, and in the whole belt more than 50 volcanic peaks, active, dormant or extinct, are counted.

On a fair summer day, as you gaze at one of these beautiful, tranquil cones, it seems as if they were asleep forever. As the peak of Augustin, for example, rises 3,000 ft. above the encircling sea with its fine, symmetrical cone, it is a joy to behold. So peaceful does it seem that one scouts the suggestion that it could be dangerous or had ever broken the general serenity, yet no longer ago than October 6, 1883, a bright, clear day, at eight o'clock in the morning, a loud report was heard by the settlers at a little place called English Harbor. Dense volumes of smoke immediately were seen to rise from the volcano of Augustin, about 50 miles away, and it was plain that a great catastrophe had occurred. Later inspection revealed a cataclysm. The island peak had been rent asunder, till from one side to the other the sea flowed through its center, and one-half of the mountain had fallen down. A party of natives who had been there after sea otter were never seen again. Thirty feet high, an earthquake wave swept the shores, but fortunately, coming on a low tide, the people at English Harbor were preserved from destruction. The sky grew dark. Thick dust showered over the whole region. Lamps were lighted. At night flames were seen issuing from the summit; at least so the settlers thought, but their flames were probably only the reflection of the molten lava on the issuing steam. The next day, when the peak could be clearly seen once more, it was found to be bare of snow. In the strait between the volcano and the mainland a new island appeared, a mile and a half long and 75 feet high. Other peaks in sympathy ejected dust and steam. Forests of the shores were killed by the rain of hot ashes. Yet only a year before this happened it was not known that Augustin was a volcano. In the August preceding the eruption a film of smoke arose from the peak and revealed its true nature.

Only a few days before this fearful eruption of Augustin, about which we should have heard much had any considerable settlement been in that vicinity, tremendous activity was in progress toward the other end of this long and narrow volcanic area. About 30 miles north of the island of Umnak in 1796 a new volcano had suddenly appeared above the water, and now as a companion to it another larger one arose close at hand. The older one had by this time entirely ceased its activity, but the new one took up the cause, and for years decorated the locality with whirling steam and lurid fires. In 1891 it was still enveloped in steam clouds arising from small fissures and crater-like openings. This steam, charged with dust, is commonly called smoke, but in reality a volcano does not smoke.

Where the subterranean fires in this entire volcanic belt burn most fiercely is on the island of Unimak, whose length and breadth are respectively only 60 and 20 miles. It is a veritable Hades. A very narrow strait separates it from the extreme end of the peninsula of Alaska and a string of small islands leads across to Unalaska, consequently it is not a difficult place to get at, as places go in that part of the world. It is also a richer island, more fertile, and with better food supply than many others of the archipelago, yet it is uninhabited and has been for most of the last century. This is probably to be ascribed to the violence of its subterranean fires, although a diabolical massacre by the Russians is also mentioned as a cause. But the entire area is full of volcanic vents, culminating in the stately peak of Shishaldin, some 9,000 feet high. This superb volcano is in a state of constant mild activity, and on a fair day, with the long trail of smoke from its pointed summit, is one of the most graceful mountains on earth, suggesting Vesuvius, although more than twice as high, and strongly resembling also the famous sacred mountain of Japan, though a more perfect cone than either of these. It also vies with St. Helens in Washington, the most perfect cone on our Pacific coast. From Shishaldin, according to Westdahl of the Coast Survey, active discharges "come in puffs like steam at first, and rising probably 100 ft. or more above the summit, then turn darker in color and stream off horizontally with the direction of the wind." The snow line is about 1,800 ft. above the sea. At about 3,000 ft. below the summit the regular cone begins to spread and the slopes below are far less precipitous, giving the long, graceful outline which, with the sharp peak, renders this volcano strikingly symmetrical.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and to give information dealing with the practice of mining, milling and smelting.

NATIVE LEAD is rarely found, though reported from Canada.

WHERE veins unite in depth the senior locator takes all below the union of both veins.

IN drifting it is always advisable to place the bar to which the machine drill is clamped in a horizontal position.

THE depth of a shaft may be approximately measured by means of an anerold barometer, taking the mean of a number of readings.

SEVERAL BULLETINS of the California State Mining Bureau are out of print, among them No. 2, 'Methods of Mine Timbering.'

NOT infrequently a fault plane intersecting a vein may be the direct cause of an enrichment of the vein for some distance above the fault.

THE owner of a water right cannot carry a ditch, pipeline or flume across the land of others without first having obtained a right of way.

THERE is no such mineral as gold radium. Radium is an element, recently discovered. It is usually associated with the various ores of uranium, and is comparatively rare.

BASALTIC and other basic volcanic rocks are not known to contain gold, unless the metal is carried into zones of fracture in such rocks subsequent to their extrusion.

THE 21st annual report of the United States Geological Survey, Part III, gives a comprehensive description of localities in the Black Hills of South Dakota by T. A. Jagger, Jr.

IT is good business to place a skip in a shaft of as large sectional area as practicable, and of no greater depth than is reasonably consistent with the hoisting power available.

ALL first-class concentrating machines have devices for leveling. Where these are not provided the machines may be leveled by driving wedges beneath the frame at the proper place.

ONE cause of disaster in working metal mines by pillar and room method is in leaving pillars in large veins no larger than those which have been found sufficient to support the walls in small veins.

THE small hand pneumatic hammer-drills have been successfully employed in drilling holes in hard rock to a depth of four or five feet, but their greatest economy is found in drilling the first 24 to 30 inches.

SHAFTS SUNK within the limits of a town or close to a public highway should be surrounded by a fence for the safety of passers by. Montana has a State law making it compulsory to provide such protection.

IN mines where electric wires are carried through shafts, drifts, and other main workings, they should be placed where they are not readily reached by workmen, in the ordinary performance of their duties.

IN chemical laboratory work, all quantities are stated in metric terms. A standard solution of potassium cyanide written '44.5 per liter of water,' means that 44.5 grams of the salt have been added to one liter of water.

WIRE ROPE must not be coiled and uncoiled like other rope, but must be wound on a reel or rolled up on itself in a coil, like a wheel rolled along the ground. Coiling and uncoiling wire rope will cause it to kink after a few turns.

THE Civil Code of California thus legally defines hydraulic mining: "Hydraulic mining within the meaning of this title is mining by means of the application of water under pressure through a nozzle against a natural bank."

ONE of the most important functions of receivers of air compressors is to reduce or wholly destroy the pulsations caused by the rapid discharge of air from the cylinder into the pipe-line. Its secondary purpose is to act as a storage receptacle.

NEVER blow through the tube of a transit or level after the lenses have been removed, if the tube contains cross-hairs, as a vigorous blast will blow out the cross-hairs as well as any accumulated dust. The latter will do no harm if the lenses are clean.

A FEATURE of mine development too often overlooked is suitable provision for drainage of drifts, crosscuts, etc. A drain should be provided in all such cuttings—either in the center, under the tracks, or at one side. Not only is it necessary to provide such drains, but they should be kept open. Often haste to make headway is responsible for lack of drains, and for poor timbering, both of which later become more expensive than if properly attended to at first.

ORDINARY SOLDER, it is claimed, can be employed in soldering aluminum, if the surface is previously prepared by melting together at a low red heat and mixing ten parts of soft solder made of tin and lead, five parts pure zinc and six parts aluminum.

A COMPETENT LEGAL AUTHORITY states that the stockholders of a mining company which have failed to perform the required assessment work on unpatented claims, thereby losing title to them by default, may relocate such claims in their own names.

THE character and value of the surface outcrop of a vein is not a safe or reliable index of what may be found in depth. A poor, low-grade outcrop may overlie a rich orebody, and a rich deposit at the surface may prove to be only superficial in character.

IF the tables issued by the manufacturers of plow-steel ropes are reliable, a hoisting rope of this class will break of its own weight in suspension when 60,000 ft. in length. An inch plow-steel rope breaks under a strain of 47 tons, and a 2-inch rope breaks at 189 tons.

THE so-called free-milling quartz gold ores of California contain on an average of 2% sulphides, principally pyrite, which assay from $20 to $200 per ton. Much of this is concentrated on machines and the concentrates treated by the Plattner process of chlorination or shipped direct to the smelters.

WHERE borax minerals occur in vein form—intercalated in sedimentary beds, which have been uplifted—the vein may be located as a lode claim; but where the mineral occurs in the bed of a recent dry lake, as those near Calico and in Death Valley, the claims are taken as placers, in the usual manner.

TO CUT a glass water-gauge, wet a new three-cornered file, draw it several times around the place where it is desired to break the glass; then hold the tube firmly in both hands, the thumbs on either side of the file-cut and bend the glass. If the filing has been properly done, the gauge glass will break as desired.

THE small adjusting screws of drawing and similar instruments, which become rusted or work hard from other causes, may be placed in good condition by running the point of a sharp pencil around the thread, which is much better than oil of any kind, as there is no danger of soiling a drawing by contact with it.

WHERE A locates and works a placer claim and abandons it, and subsequently B makes a lode location on the same ground, so long as the lode location has a legal standing and the law is observed, A may not again locate the placer. Lodes may be located within placers, but placers may not be taken within lode claims.

UNDERHAND STOPING is not ordinarily practiced, but this method of mining is occasionally resorted to to secure ore discovered in a drift at some distance from a shaft. It is seldom attempted except on rich ore. Perhaps the better method would be to sink a winze on the orebody and remove the ore by overhand stoping.

NO TITLE can be obtained to town lots staked on a valid and legally subsisting mining claim without the consent of the owner of the mine. In new districts much litigation sometimes results from the wholesale appropriation by many of town lots on the previously located mining claims of others. Such has been the case at Tonopah, Goldfield and elsewhere.

MORE than one machine may be clamped to a single bar in either shaft-sinking or drifting. In a shaft 10 ft. square it would probably be found difficult to set bars sufficiently rigid for the successful operation of large machine drills, owing to the excessive vibration of so long a bar. Tripods could be utilized in such a case, but they are less satisfactory than bars for shaft work.

THE Government of the United States coins silver and other metals in accordance with the statutes regulating the coinage. A large proportion of the silver mined is coined, but it is mostly for countries of the Orient and India. The output of copper for the world in 1904 was about 640,000 metric tons. It is used mostly in electrical work and in the manufacture of brass and other alloys.

NO mine should be operated without carefully prepared maps showing all the workings, longitudinally and in cross section and plan. They should indicate the character of wall rocks, the width of the vein and any other physical features of importance. It is dangerous to carry on mining operations in proximity to old flooded workings without being provided with good maps of such old workings.

THERE is no law in California, so far as known to 'Concentrates,' which requires that air-compressors or receivers be equipped with a safety valve. The necessity for such attachment is so evident that no one of experience would think of attempting to run a compressor without a safety valve any more than without a pressure gauge. A safety valve will work on an air compressor in exactly the same way as on a steam engine, and is just as essential to safety.

THERE has been practically no commercial production of antimony in the United States since 1901. The tariff on antimony was removed in 1902, which gives foreign antimony, including stibnite (antimony sulphide), free entry into this country. The price of the metal at present is 13 to 14c. per pound. The principal use for antimony is in the manufacture of alloys with tin, lead, zinc, and other metals. The total consumption of the metal in the United States does not exceed 4,000 tons. An antimony mine must be most favorably situated to compete with existing conditions.

THE most frequent cause of accident in handling nitro powders is in thawing it. Nitroglycerine compounds become comparatively harmless at about 40° F. and do not explode readily at that temperature. It is in the effort to soften the frozen powder that the danger lies. Open fires, ovens, and direct steam heat, should be avoided, as well as the tops of stoves, boilers, cylinders of both engines and compressors. The powder should be placed in a can set in warm water, and carefully covered. The powder thaws slowly but effectually, and the operation can be performed without danger.

THE greater part of the world's demand for pumice is supplied by a deposit in the northeast part of the Lipari island, in the Mediterranean. A large deposit of pumice in Nebraska, and another in Utah, supplies a great part of the demand in the United States, the remainder coming mostly from the Hawaiian islands. Pumice occurs in a number of places in southern California, on the Colorado desert, and also in the Great Basin in Nevada. The amount of pumice mined in the United States is less than 1,000 tons annually, worth about $3 per ton. The quantity imported varies greatly—from none to upwards of $80,000 per annum.

IT is doubtful if a kiln can be built at small cost which will roast sulphide ore satisfactorily and which would be continuous in its operation. The mechanically rabbled reverberatory is one kind of furnace that accomplishes this, also several types of multiple-hearth furnace. Beside these are rotary furnaces, such as the White-Howell and the Bruckner. Heap roasting or stall roasting is the best for those having small capital, or not desiring to invest too great a sum in equipment. The Alaska ore might be burned in heaps before stamping. This would desulphurize some of the pyrite and render the ore subject to more rapid crushing.

A TWO-COMPARTMENT SHAFT, 5 by 11 ft. in the clear, requires about 1,000 ft. of timber, board measure, to the set. This includes the heavy timbers (wall-plates, end-plates, divider, four-posts, and the necessary lagging, blocking, ladders, etc.) Shaft timbers are framed by hand generally, and the framing is therefore slower and more expensive, than where machines are used in framing timbers for square sets. The length of time required to put a set of shaft timbers in place depends on the character and condition of the ground and on the experience of the men. Ordinarily a set of timbers may be placed in an inclined shaft in less time than is required to place them in a vertical shaft.

IF we had sufficiently good eyesight to detect the temporary cessation of motion in Polaris, the time of greatest elongation could be determined by that means. As an instrument is necessary, however, to determine the variation, it might as well be used in determining the elongation *with* an instrument (transit). The method is as follows: Fifteen to twenty minutes before time of eastern or western elongation (found from the solar ephemeris), have the transit set up and carefully centered over a stake previously driven and marked with a center-point. Bring the vertical hair to cut Polaris and follow the star along to right or left, as case might be, by means of the micrometer screw. Approaching elongation, the star appears to move more slowly, and finally moves vertically upward or downward along the vertical hair. Careful observation is required here, and the angle can be read at leisure.

EFFORTS made to ascertain whether the increase of temperature with depth is uniform in mines throughout the world have shown that it is not. The rate of increase is apparently dependent to some extent upon the character of the rocks intersected by the shaft, but more so by local conditions. The deepest shaft is a little over 5,000 ft. The deepest bore-hole is something over 6,000 ft., yet this is but a mere pin-prick in the crust of the earth. Assuming the solid crust to be 200 miles in thickness, then a shaft a mile deep would penetrate but one two-hundredth of this distance—the outer crust or shell. In a globe 20 in. in diameter representing the earth, the 200 miles of solid crust would be a shell one-half inch in thickness, and the shaft, 5,000 ft. deep, would be but a scratch. On such a globe the coat of varnish covering the ocean would be proportionally equivalent to a sea about 12,000 ft. deep. Many ideas have been advanced by scientists dealing with conditions in the interior of the earth, but they are at best theories and nothing definite is known of them.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

THE BEST SHAPE FOR A SHAFT.

The Editor:

Sir — This discussion might perhaps be better termed the best shape for a particular shaft, since it relates chiefly to a concrete instance of a shaft 10 ft. square and 320 ft. deep which has to be sunk to an ultimate depth of 2,300 ft. Mr. Burrows proposes to use the old portion of the shaft for two hoisting ways each 4 by 5 ft. and at its bottom to add at one end a pump and ladder-way 5 by 5 ft., while Mr. Storms suggests a very practical but perhaps costly method of utilizing the present 10 by 10-ft. shaft and carrying it down that size for the entire depth. I would point out that the depth already sunk is only 13.9% of the entire distance, and that it might be well not to let the tail wag the dog.

Judging from experience, the best shape is that suggested by Mr. Burrows of 5 by 16 ft. The 'jog' alluded to by that gentleman should be made of spiral shape, the roof reaching up perhaps 40 ft. before finally curving into the unused space of the present 10 by 10-ft. shaft. This will allow of easy bends in the water column, air-pipes, etc., and a ready transfer of the ladderway, while avoiding any necessity of ever stripping the upper portion of this old shaft which can remain as it is.

It is, of course, assumed that pumping will be done by electricity as in deep shafts on the Rand, where it has not been found necessary to have an extra engine for handling the pumps and pipes. This can all be done perfectly well from the main hoisting compartments, and after the pipes are once installed in their stations and the water-column in place, there is little or nothing to be done in that compartment requiring the use of a hoisting engine.

As Mr. Storms points out, the 10 by 16-ft. shape is quite out of the question as unnecessarily large and much too costly. It is as extravagant to sink too large a shaft as it is to instal a 1,000-h. p. engine to do 500 h. p. of work, and even more so. That is to say, a shaft must be worked to 100% efficiency, or as near to that as may be, and not be sunk of such a size that it can never be called upon for more than 40 or 50% of its capacity. The 10 by 10-ft. shaft would require the breaking and hoisting of 25% more ground than the 5 by 16-ft. and to no purpose, since the ground that can be handled through two well-equipped hoisting compartments is enormous.

The record cited by Mr. Storms from my paper on deep-level shafts has now been exceeded at De Beers and by a very considerable tonnage from a greater depth, but I have not the figures at hand.

As to greater facility in breaking the ground in a square or round shaft, this advantage is more theoretical than practical and I know of no place where they have beaten the shaft-sinking record of the Transvaal in rectangular shafts, namely 203 ft. sunk in one month.

The method of timbering, to so speak of the steel I-beam dividers, etc., suggested by Mr. Storms, is ingenious. More room could be obtained, however, by using dividers but four inches wide on the flange (instead of eight inches) which would be amply strong. The steel framing would, however, be expensive, while according to all information the character of the ground does not call for such strength of material, and it involves the sinking of an unnecessarily large and therefore more costly shaft, not to mention the sacrificing of 86% of the permanent shaft in order to make it conform to the existing 14 per cent.

As regards size of hoisting compartments for shafts 2,000 ft. deep, or more, I much prefer a compartment 5 by 6 ft. instead of the proposed 4 by 5-ft., but I have no doubt the latter can be made to answer all requirements.

THOS. HAIGHT LEGGETT.

San Francisco, March 6, 1906.

AMALGAMATED PLATES.

The Editor:

Sir—The introduction of the use of amalgamated plates was one of the most important steps in the progress of gold-milling operations. Yet there seems to be nowhere in the literature of that important subject an exact statement as to where, when, and by whom they were introduced. It is to be hoped that someone familiar with the facts of the case will present them, so that they may become a matter of record, before the generation which can speak from knowledge passes away.

THOMAS T. READ.

New York, March 2, 1906.

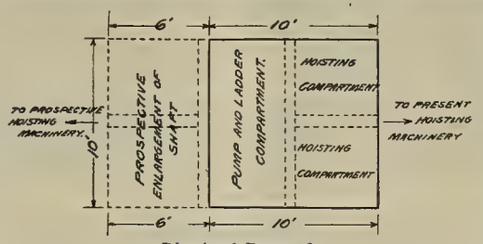
[We trust some of our readers in California will be able to give the information required. The use of plated copper in stamp-mills originated in California, and there is reason to believe that copper tables were used here first, the earlier Georgian practice being based on the use of blanket strakes.—EDITOR].

THE BEST SHAPE FOR A SHAFT.

The Editor:

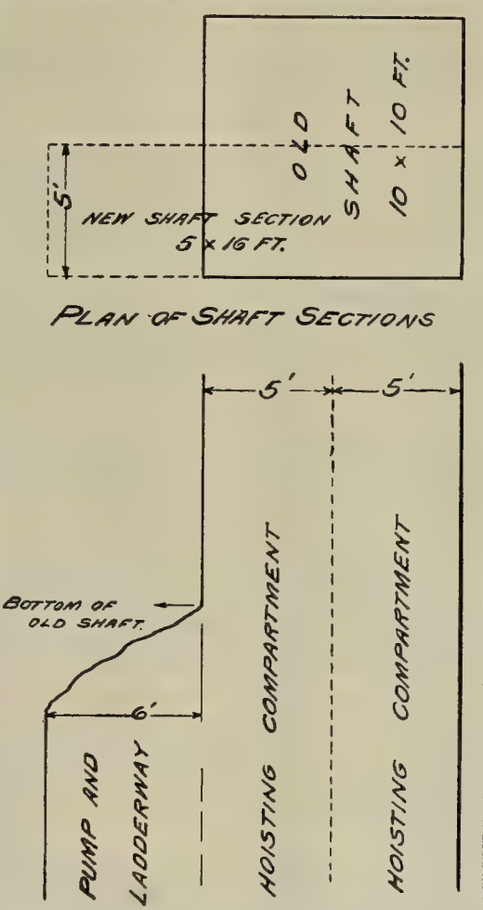
Sir—The interesting letter of R. H. Burrows in your issue of February 24, on 'The Best Shape for a Shaft,' re-opens a subject that has been often discussed by mining engineers.

Under the circumstances described by Mr. Burrows as existing at his mine, it does not entirely meet the case to say that the accepted practice in all the newer mining regions of the world is to sink shafts whose cross-section is long and narrow rather than that which is wide and approaches a square. In this



Directors' Proposal.

instance it is planned to sink to a depth of 2,300 ft., utilizing an old shaft 320 ft. deep by 10 ft. square which happens to occupy the site chosen. A difference of opinion arose between the management and the board of directors. The manager proposed to sink from the bottom of the old shaft with a section of 5 by 16 ft., comprising two hoisting-compartments 5 by 5 ft. each, and a ladder and pump-way. Thus only one-half the section of the 320 ft. of



Manager's Proposal.

old shaft would be utilized. The directors favored the plan of using the entire section of the old shaft, a large pump-way lying against the ends of the two hoisting-compartments.*

The writer of the present communication distinctly favors the manager's plan. In carrying it out there would be some inconvenience in handling pumps and piping during installation and possibly in making repairs, but the timbering would be of stronger and better design than for the square section and would cost less. Furthermore, any subsequent enlargement for adding more hoisting-compartments could be made equally well and at a smaller cost.

The particular problem presented here may be considered from four points of view:

1. *Timbering.*—It is stated that the ground is sufficiently firm to make wall- or end-plates unnecessary. Therefore, in a long and narrow shaft one end-plate and two dividers only, set in hitches in the walls, would be required. These dividers and end-plate would carry the cage guides and being short would provide an efficient general support for the walls at 5-ft. intervals across the shaft.

For the square shaft, on the other hand, the hoisting-compartments are so placed that, if cages and guides of ordinary form be used, two 5-ft. wall-plates, in addition to one short divider, would be necessary to support the guides. The quantity of timber in these plates and divider would be the same as for the three timbers per set for the long section, and in addition there must be a center divider of double length (10 ft.). Besides, to furnish equal strength, the 10-ft. divider would have to be of larger section.

On the basis of 8 by 8-in. timbers, set 6 ft. apart vertically, which would probably be suitable for the conditions specified by Mr. Burrows, 1,335 ft. of timber, board measure, would be required per 100 ft. of shaft of the long section, as against 2,220 ft. per 100 ft. of the square section. (It may be noted here that 8 by 8-in. and even 6 by 6-in. timber has been used satisfactorily on the Rand for important shafts.)

In this estimate no account is taken of the extra length of timber required for hitches, which would be nearly the same for both cases; nor of the possible larger size of timber for the 10-ft. center divider of the 10 by 10-ft. shaft; and, as complete ring sets are not required, both posts and lagging would be omitted.

2. *Drilling and Blasting.*—It was urged in favor of continuing the 10 by 10-ft. section that a deeper cut could be made than in an area of 5 by 16 ft. This is questionable for the following reasons: A substantial advantage of a long section is that the width of collar between the two lines of center-cut holes may be made relatively great, while still allowing ample room for setting up and operating the drills. That is, the vertical angle between the rows of cut holes is large and for the same vertical depth per round less explosive is required. By laying out to scale the two shaft-sections, with their vertical projections, it will be seen that for a 10 by 10-ft. section the width of collar could not be much more than 2 ft. 6 in. This would leave a width of only 3 ft. 9 in. on each side for setting up the drills. And in this space two side rounds would have to be put in, since it is extremely improbable that a single side round would break the ground, even with heavy charges that would tend to shatter the walls.

For the 10 by 10-ft. shaft I should estimate ten holes (five on a side) for the center cut, and two rows of four holes on each side to square up: total 26 holes. For the 5 by 16-ft. section a maximum of eight holes would be required for the cut, with two rows of three holes apiece on each side for squaring: total, say, 20 holes. The vertical angle between the rows of cut holes could be made nearly double as great as for the 10 by 10-ft. section; and the charges could therefore be smaller, beside enabling the holes to bottom up better.

As to the amount of rock to be broken and mucked per round, I think Mr. Burrows is right in maintaining that in ground that drills well the total speed of sinking depends more on the volume of ground to be mucked and hoisted than on the total linear feet of hole to be drilled. Assuming the weight of rock to be at the rate of 13 cu. ft. per ton, there would be 7.7 tons per foot of shaft to be mucked in the 10 by 10-ft. shaft, and 6.15 tons per foot in the 5 by 16-ft. shaft. Without knowing the local conditions, an exact comparison in figures cannot be made either as to blasting or mucking, but the above considerations point to a substantial difference in favor of the 5 by 16-ft. section.

3. *Convenience of Laying Out Shaft Stations.*—As long as the shaft has but two hoisting-compartments the conditions in this respect would be about the same for both sections; but referring to the sketch in Mr. Burrows' letter of the enlarged 10 by 10-ft. shaft, the provision for two additional compartments materially alters the case.

The pairs of hoisting-compartments are back-to-back on opposite sides of the shaft, with the pump and ladder-way between them. The landings are consequently separated, and to connect them a large drift must be made around at least one side of the shaft. The cars must be run off the cages in opposite directions, and more curves therefore become necessary in the tracks connecting with the crosscut to the vein. All this will cost more, and it will be more inconvenient to handle the cars at each station, than for a four-compartment shaft made by increasing the section of the 5 by 16-ft. shaft to, say, 5 by 26 ft. In the latter case the landings will be side by side and much more easily arranged with respect to the main crosscut.

4. *Surface Plant.*—The matter of the relative positions of the shaft-stations is directly connected also

*It would appear that an error was made in printing Mr. Burrows' sketches illustrating the proposals of the manager and of the directors. The titles of the sketches should be reversed.

[Professor Peele is quite right. We re-publish the two drawings referred to, and this time they are correctly labeled. Although the titles were transposed, the text was so definite as to have prevented confusion.—EDITOR].

with the design of the hoisting plant at the surface. For the 10 by 10-ft. shaft it would be difficult to avoid the construction of two engine-houses on opposite sides of the shaft and separated by a distance of say 150 ft. The boiler-house would be either close to one engine-house or between the two. For such a plant the cost of installation and running expenses would evidently be greater than for the other design, in which the hoisting-compartments are side by side, and the engines will be placed in a single larger building.

It is superfluous here to consider the design of the hoisting plant and the question of steam economy, further than to say that for a single engine-house the four drums might be driven through friction-clutches by one constant-motion engine, while for the other design two independent engines would of course be required.

In conclusion, Mr. Editor, though the subject is far from being exhausted in this communication, the weight of advantage appears to me to be decidedly in favor of the 5 by 16-ft. shaft.

ROBERT PEELE.

School of Mines, Columbia University, New York, March 6, 1906.

THE BEST SHAPE FOR A SHAFT.

The Editor:

Sir—As one of the mining fraternity referred to by R. H. Burrows in his communication in your issue of February 24, I am inclined to make a few remarks.

The problem troubling your correspondent was briefly, whether it were the wiser to continue a three-compartment 10 by 10-ft. vertical shaft now 320 ft. deep, or to remodel it into a 5 by 10 shaft of two compartments (cutting off an area 5 by 10) to present depth, and thence adding, at one end, a third compartment (5 by 6 ft.) as a pump and ladder-way; the former plan being proposed by the directors; the latter, by the manager; the contemplated ultimate depth to be 2,300 ft., and the capacity 1,000 tons per day.

The manager's plan is decidedly the best, for the following principal reasons:

1. The 5 by 16-ft. shaft is easier timbered, is more rigid, and when in bad ground is more readily secured, than a 10 by 10-ft. shaft.
2. The 5 by 16-ft. shaft will be sunk and timbered for less cost than the other.
3. The position of the 4 by 10-ft. pump and ladder-way in the 10 by 10-ft. shaft, back of the two hoisting-compartments, is very undesirable, not being convenient of access and rendering the hoisting-compartments accessible only on one side.
4. Cage-ways should always be free to open out in two opposite directions, at stations.
5. The two hoisting-compartments in the 5 by 16-ft. shaft can handle 1,000 tons daily, if necessary. It is simply a question of equipment.
6. If a third compartment for hoisting becomes necessary, it may be added at one end of the 5 by 16-ft. shaft, to better advantage than the 10 by 10-ft. shaft can be enlarged.

One feature I am surprised your correspondent does not suggest. If his property warrants so large a shaft to a possible depth of 2,300 ft., it should warrant carrying his 5 by 6 pump-way to the surface to start with, in his proposed 5 by 16 shaft, and thus do away with the "jog at the bottom of the old shaft."

T. E. SCHWARZ.

Denver, March 3, 1906.

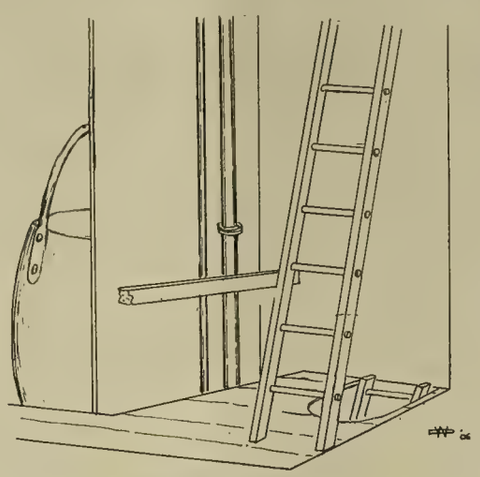
MAKING MINE LADDERS.

The Editor:

Sir—Mr. Alderson is to be congratulated on his practical article on mine ladders, one of the minor economic subjects that generally do not receive enough attention. A note or two from Nova Scotia may be of interest. In that country, where the metal mines are not usually of great depth, and where cages are seldom used, the ladderway is the chief means of entrance and exit to and from the mine. The mining regulations require that it shall be made efficient and specifically stipulate that ladders shall not be placed in a vertical or overhanging position, on the contrary they must be placed at as flat an angle as the man-way will allow, and must have platforms placed at intervals not greater than 60 ft. In the annual report for the past year it has been recommended, among other changes, that this distance be altered to 20 ft. A fall to a depth of 60 ft. has often resulted in effects as injurious as a fall of several hundred feet.

One of the best examples of a properly equipped ladderway that has come under my notice is at the Bluenose mine at Goldenville, Nova Scotia. The shaft which is practically vertical—at 87° to the horizontal—is over 500 ft. deep and is divided into two compartments—one for the tub or bucket, the other for ladders and pump. The ladders are a little over 20 ft. long and, if I remember rightly, are constructed of 2 by 4 in. uprights with rounds of iron pipe placed at intervals of 12 in. The ladders are given the greatest inclination possible and the manholes are placed directly under the ladder and each other. These are semicircular in shape, a little wider than the ladder and about 24 in. from front to back. This arrangement necessitates stepping round from bottom of ladder to man-hole, but in a climb of 400 ft. to 500 ft. this is a grateful pause. Moreover, this arrangement consumes no more time and is not more irksome than when hatches are used on a continuous ladder-way, nor is it so dangerous as the 'staggered' form of ladder-way where the ladders and man-holes are placed alternately at opposite sides of the shaft. The pump-discharge and air-pipes, etc., were also contained in this compartment, but were separated by a hand-rail. The rule at this mine preventing men from riding on the tub was strictly enforced and they were allowed ten minutes for entering and the same time for leaving the mine.

It will be observed that in the above method, splicing is not necessary, as the ladders rest independently on the platform and wall or the timbers of the shaft. In splicing in an inclined shaft, dependence should not be placed simply on the strips connected by nails to the uprights, but the ladders should also be connected by proper hooks and in a continuous ladder-way every second ladder at least



Shaft and Ladder-way.

should be strongly and independently fastened by spikes or otherwise to the shaft timbers.

I do not agree in not 'gaining in' the ends of slats in mine ladders. As Mr. Alderson himself states, the nails rust and if not 'gained in' a nasty fall is likely to occur on the slat giving way. The very swelling mentioned is a source of safety. The timberman or mine carpenter on his rounds always has, or should have, the few tools with him necessary to get the broken slat off the uprights.

D'ARCY WEATHERBE.

PYRITE SMELTING WITHOUT COKE.

The Editor:

Sir—I have read with much appreciation Lewis Wright's article on 'Pyrite Smelting Without Coke,' printed in your issue of February 24. It is very interesting, but would be more valuable if the writer had not omitted some important matters, which I hope to be excused for calling to his attention.

It is desirable to know what fluxes were used. He speaks of a varying percentage of flux, but without saying what kind it is. How much limestone and silica does Mr. Wright add to his charges?

Second—How many tons of the different charges spoken of went into a single ton of matte? This is very important to know, as without this knowledge all his figures go for nothing.

Third—How much do the slags assay? Unless the slags falling from the higher concentration charges are cleaner than customary, it might not pay to run a matte of converting grade at the first turn-out of the box. Some have found it to pay better to make a low-grade matte at first and to re-concentrate it afterward, instead of trying to produce a richer product at first.

Fourth—How hot does Mr. Wright run his blast? The meager information that it requires from 1 to 1.25% of fuel, based as coke, to heat it is hardly sufficient, as so much depends on the apparatus used.

We can scarcely expect business matters to be revealed, or I would ask about the cost of smelting at Keswick. It is known that a great many men are employed there, some say one man to each ton of ore reduced in a day. This can hardly be so, or the gentleman would not bring the plant forward as something to be studied and written about, but we may ask for just a few figures about so interesting a work. Thanking Mr. Wright for the pleasure he has given me, and expecting further enlightenment.

R. RODGERS DECEMGE.

Prescott, Arizona, March 10, 1906.

Steam-Shovel in Copper Mining.

At the Cactus mine, in Beaver county, Utah, the steam-shovel is being used successfully and we learn that a similar machine is to be put to work shortly on the disseminated copper ore in the monzonite formation of Bingham. The Cactus mine is on the western slope of the San Francisco mountains, near the new town of Newhouse and four and a half miles northwest of Frisco. It lies on the western slope of this 'Basin range.' The deposit is essentially a pyritic impregnation of a zone of fracture in a body of monzonite, locally known as 'granite.' This is intrusive in limestone. The ore is mainly pyrite with chalcopyrite, and contains but little lead or zinc. The orebody is stated to be from 100 to 175 ft. wide and 700 ft. long.

The ore is first disintegrated by blasting and is then moved by the steam-shovel. Holes are drilled 25 ft. deep and 10 ft. apart. After chambering, they are filled with black powder and fired. The material thus loosened is loaded into 24-ton Thew cars with the steam-shovel, having a ¾ cu. yd. bucket. This handles 400 tons in 10 hours and is now being worked by day and night shift. So far, the steam-shovel has been employed only in stripping the overburden, but it is soon to be started on milling ore. For its operation six men are required, one operator and two attendants, and three trammers. Four men do the drilling. Compressed air is used as power because of the lack of water fit for boiler purpose. The cost is said to be less than 40c. per ton in stripping, and it is to be further reduced by re-heating the air.

The mine is worked by the Boston Consolidated Mining Company, of which Lafayette Hanchett is manager. This same company now has a 95-ton Vulcan shovel at Bingham Canyon and is awaiting the completion of the railroad to its mines before starting work. The Utah Copper Company has a similar shovel in readiness to work adjoining ground and the Boston Consolidated has placed orders for another. These will first be used in removing the overburden and afterward in mining the ore itself.

This ore also is porphyry impregnated with copper sulphide, averaging 2% copper. It is to be crushed and concentrated; the concentrate being smelted at the new Garfield works, which are expected to be running in June. These two companies confidently expect to be able to move 10,000 tons of ore per day within the next six months.

Copper River, Alaska.

A most important element to consider in relation to the future development of this region is the probable condition of the deeper-lying ores and the presence or absence of bonanzas. In 1900, when Messrs. Schrader and Spencer examined the Nikolai mine, a shaft had been sunk to a depth of 30 ft., and a tunnel in the Warner prospect, which has now been driven 18 ft., was examined in 1902. Except in these two cases we have no evidence as to underground conditions in the region itself, but reasoning by analogy from other regions on the basis of the surface conditions prevailing in the Nizina valley, certain probabilities may be indicated.

Climatic conditions are believed by geologists generally to be potent factors in the alteration of mineral deposits by surface water, in the oxidation of a surface zone, the leaching of this oxidized zone, and the re-deposition of the derived products in depth, as oxide or sulphide enrichments. The low temperatures of interior Alaska at present and the lower temperatures, or at least the more uniformly low temperatures, during the recent geologic past, when glaciation was much more extensive than now, are conditions unfavorable to those chemical processes, to which certain important enrichments—the secondary bonanzas of many copper camps—are believed to be due.

The region is extensively glaciated, but the present glaciers are but insignificant remnants of their predecessors. Probably no single occurrence of ore has been described which has not recently been buried under an ice mass and subjected to an unknown amount of ice erosion, resulting in the removal of those surface forms of the ores which may previously have accumulated.

The present surface ores are usually the richer sulphides, bornite, and chalcocite. No gossan cap over any of the veins and no extensive deposits of oxides or carbonates have been observed, the latter minerals, where seen, being mere surface films and obviously due to recent atmospheric action.

It is probable, then, that there has been no deep alteration, because of climatic conditions, and that glacial action has recently removed much of that shallow altered zone which perhaps did exist, these conditions together resulting in the presence of bornite and chalcocite as the surface ores, and leading us to expect no general increase in richness with depth. The present surface zone is the one that corresponds to the bonanzas due to secondary enrichment, in mines further south, and the changes to be expected in deeper explorations are changes from the richer sulphides to chalcopyrite.—Walter C. Mendenhall, *U. S. Geological Survey.*

Improved Shaft Equipment.

Written for the MINING AND SCIENTIFIC PRESS by S. A. WORCESTER.

The arrangement which is here described and illustrated is one which I recently designed for the Golden Cycle Mining Company, at Cripple Creek, and is to supersede an arrangement using cages and tramming cars by hand to the ore-house, an average distance of 150 ft. The new arrangement will save, probably, $9 to $15 each 8-hour shift. The plant will be used for handling ore only, all men, timbers, supplies and waste being handled through a nearby shaft. The skip-boxes are made of ⅜-in. plate, with a bottom lining of 2-in. oak covered by ½-in. plate, and have a capacity of 50 cu. ft. each. The ore averages 21 cu. ft. per ton, so that a load of two tons does not quite fill the skip and there is no need of spilling ore down the shaft. Aprons 16 in. high at the sides of the skip-boxes prevent ore from falling down the shaft when piled high in the center of the skip. The mine-cars are dumped directly into the skips. The skip-frames are constructed so that if at any time it is desired to use them as cages, for handling machinery or any other purpose, the boxes can be easily removed by withdrawing the pivot shaft, when, by placing a wooden false floor on the cross-bars, a complete cage is the result. Slanting oil-holes are drilled in the ends of the pivot shafts, which are stationary in the frames, and the bearings can always be oiled, whatever the position of the skip-boxes relative to the frames. Oak foot-boards are placed at the top of the skip-frame or cross-head for the skip-tender to stand upon and a bonnet is provided for protection from falling objects. The bonnet is supported by rods above the skip-frame and has shoes embracing the guides. The safety-dogs are steel castings with planed teeth; the springs are protected from injury when dumping cars into the skip, or from any other cause, by placing them between the two 8-in. channels which form the top or cross-head of the skip-frame. The guides which engage the rollers on the skip-body for tipping and dumping it are curved to a 6-ft. radius for about one-half their length, and a 3-ft. radius for the remainder, so that as the motion of the skip is retarded near the end of the trip, its dumping movement is accelerated. This reduces the strain on the parts and the liability to accident, and causes the skip to right itself gently. A bin, having a capacity of five to six loads, receives the ore from the skips. The upper part of the bin is lined with ¼-in. steel plates, and the lower part, which is subject to the greatest wear and severest blows, is lined with ⅜-in. steel. The gate, with an opening of 20 by 30 in., is made of ½-in. steel, re-inforced by heavy angles, and is operated by a 6 by 20 in. air cylinder, controlled by a four-way cock within convenient reach of the operator when standing on the car-platform and with the car in position for filling and for charging with air. The inclined bin-gate has less tendency to wedge ore against the adjacent slope than the vertical style and is more satisfactory in operation. The side-dump ore-car is propelled by an air-locomotive with 7 by 7 in. cylinders, having balanced valves and a simple reversing and throttle valve, similar in action to the type of valve generally used on steam elevators and like machines having only one controlling lever for the engines. The engines are built into the truck-frame and are of extremely simple construction and few parts, so as to be adapted to rough usage. When the car is brought under the bin, with the bumpers in contact, the automatic air-coupling opens two valves and the receiver, 28 by 72 in., on the car, is charged in a few seconds, without any attention from the operator, who stands on a platform between the engine cylinders, with all levers within easy reach. When the car starts the coupling-valves close automatically and prevent any escape of air. The car is assisted in starting by the air-pressure on this coupling, which amounts to nearly 500 lb., tending to separate the two parts of the coupling. Air is supplied by the mine compressors at about 100-lb. pressure. The car is stopped and held securely by a powerful brake at the operator's right hand. The brake-lever has a notched quadrant and a thumb-latch and the brake can be set so as to prevent the car from moving, which might occur when charging. Several reasons led to the adoption of air as a motive power: The nearness of compressors of ample capacity and the fact that an air-connection was necessary for operating the bin-gate; also it was not deemed advisable either to instal a special generating plant or to buy current for an electric motor; furthermore, an air-locomotive of extremely simple construction involves less outlay than an electric motor of equal torque; the shortness of the trip, averaging only 150 ft., makes the air-consumption necessarily small. As the operator must travel with the car, in order to see and regulate at all times the dumping operation, and to see that the grizzlies are kept clear and the bins properly filled, the only form of cable haulage that seems to apply practically is one using an endless rope and having two lever-grips on the car, one for the out-going and one for the returning cable. Some of the objections to this plan were, that the short turn of about 60° from the bridge into the ore-house would require a number of idlers and cause much wear on the cable and side strain on the grips; the haulage engines, sheaves, cable, etc., in the aggregate, would be more expensive than the air-locomotive; the power consumption would be greater for keeping the cable in constant motion than for making the intermittent trips with the locomotive; and the speed would be limited to that of the constantly running cable.

A review of some of the faults of older plants which are avoided by this one will be profitable: In one instance coming under my observation, counter-balanced skips dump directly into a car which go to the ore-house. Criticisms which apply to this arrangement are: (1) When the skips are hoisting the short distances from the upper levels, the car cannot make its trip quickly enough and the skips have to wait awhile at each trip. (2) If for any cause, such as, for instance, a clogged grizzly, requiring to be cleaned, the car is delayed, and skips are also delayed until it returns. (3) When the skips are delayed for any cause, the ore car is also idle and must wait for a load. In one case, where a skip dumps directly into a car, I noted that the operator's platform was placed at the rear of the car, so that it passed partly under the supposedly empty skip at each trip. On several occasions rocks of considerable size hung in the skip, and fell just as the operator was passing, and the rule was finally passed that the engineer must lower the skip far enough to avoid this danger before the car is allowed to start. This delay I easily avoid by placing the platform at the front of the car. In the instance just mentioned, the electric motor of five horsepower is geared to the forward axle only, and the two driving wheels slip during the first 10 to 30 ft. of the trip, so that the car loses time at starting. Placing the platform at the rear aggravates this trouble by throwing the weight more on the rear wheels and away from the drivers. The Golden Cycle plant has sufficient capacity in its dumping bin for 15 to 20 mine carloads and the fact that the car can always load at once from the bin without waiting for a skip enables it to keep constantly busy. In this way it gains a little each time the skip-tender uses the skip in going from one level to another, or the skip is delayed for any other cause. The immense starting pull of the car and its powerful engines enable it to make trips at the highest allowable speed; all four wheels being drivers, the slippage is reduced to a minimum.

Increased Cost of Metal Work.

Lamps, electroliers, art products and novelties of various kinds in the making of which copper, tin, brass, bronze and spelter are used, are advancing in price. Several manufacturers in New York have already sent notices of this to the retail dealers, and others will do so. Importers whose buyers have returned from the markets of Germany, France and Austria say that the prices abroad are much higher than a year ago. The public will pay more for these wares, imported and domestic, when the spring season opens.

The advances range from 10 to 25%, according to the amount of metal used, especially copper. In explanation, a manufacturer said today: "The raw copper is three cents a pound higher than a year ago, tin seven cents, lead one cent. Iron and steel also cost us more than last year. Such advances in the raw material mean more than can be readily figured. In refining and preparing the metal for use there is a constant loss in weight. If a lamp weighs six or seven pounds and sells at retail for $8 or $10, it might be supposed that a difference of three cents a pound in the raw material would not be of any consequence. But the amount of metal used is much more than the weight of the lamp in its completed condition."

Clock manufacturers say that those who have not yet put up prices of cases made of bronze and other metals are contemplating such action. The head of one firm said yesterday that if copper continues at its present level, the material will cost his company at least $30,000 more this year than last. Others agreed that the situation demanded action to save them from actually losing money on their sales, so small is the margin of profit.

In architectural shapes, building ornaments, fences and similar products, in which the amount of the metal used is much greater than in the field of art, the advance is proportionate. There are quite a number of factories in New York in these lines, and all of them have been affected by the increased cost of the metals, especially tin and copper, brass and bronze.—*The Evening Post*, New York.

FILTRATION of fine precipitates and fluids, which are turbid from decomposition, due to micro-organisms, can be readily effected by the use of tripoli. All that is necessary is to shake up or triturate with the fluid a small amount or a definite amount of tripoli and pass through the moist filter or Gooch crucible. This tripoli is almost pure, SiO_2. Small blocks arranged with a glass tubing to act as a siphon have proved excellent and expeditious to filter clear troublesome liquids.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

The white rock from Los Angeles, Cal., marked N. W. D., is rhyolite tuff.

Of the rock samples from Denver, marked H. & B. Co., the smaller piece is granulite, and contains grains of magnetite; the larger piece is largely soda-lime feldspar with a little quartz and mica. The black mineral with red streak is hematite, which is slightly magnetic, due probably to the admixture of magnetite grains.

The rocks from Stella, Cal., marked N. W. K., are: No. 1 a silicious talcose and limy schist of unusually fine grain. It contains finely disseminated pyrite. No. 2 is quartz-porphyry, which also contains pyrite. No. 3 is a felsitic dike rock in which there has developed by alteration much calcium carbonate. No. 4 is a cherty, metamorphic rock.

The rocks from Lost Cabin, Wyo., are the following: No. 1 sack contains a dark piece of silicious, much altered and iron-stained rock, and a greenish-gray rock, consisting principally of quartz and epidote. No. 2 sack contains a pink rock with a green mineral. The pink portion is orthoclase feldspar and the green is epidote. The other pieces of green rock in this sack are also epidote. No. 3 sack contains a white rock, a mixture of feldspar, and quartz with a little black mica, and is essentially granite. The brown rock in No. 3 is an iron-stained, fragmental rock cemented by lime carbonate. No. 4 sack contains a similar piece of brownish rock. The dark rock in No. 4 is a metamorphic rock, containing a large amount of iron oxide and epidote.

The rock specimens from Alleghany, Cal., are: A, amphibolite schist (talc schist); B, much decayed, apparently diorite; C, mostly quartz (metamorphic); D, a much-decayed rock, probably greenstone altered to clay and stained with iron oxide; No. 1, a greatly altered magnesian rock, with calcite and iron oxide; No. 2, chert; No. 3, dolomite, with a few crystals of pyrite; No. 4, mostly quartz—may contain gold; No. 5, quartz and iron oxide; No. 6, quartz, talc, iron oxide—may be auriferous; No. 7, talc schist; No. 8 and 9, similar to No. 6, but contains more magnesian material; No. 10, mostly quartz; No. 11, amphibolite schist; No. 12, flinty quartz, containing pyrite and stained slightly by copper carbonate; No. 13, psilomelane (manganese oxide, principally); No. 14, fine-grained amphibolite schist (commonly, though erroneously, called slate); No. 15, flinty quartz; No. 16, andesite; No. 17, diorite-aphanite. The contact between serpentine and so-called slate should be carefully prospected. Veins of gold-bearing quartz do not usually lie wholly within serpentine, though there may be exceptions. D would not ordinarily be considered a gold-bearing formation, but such ideas are prejudicial to the interest of the miner. The source of the gold is at least as high on the hillside as the highest point producing gold in the alluvial.

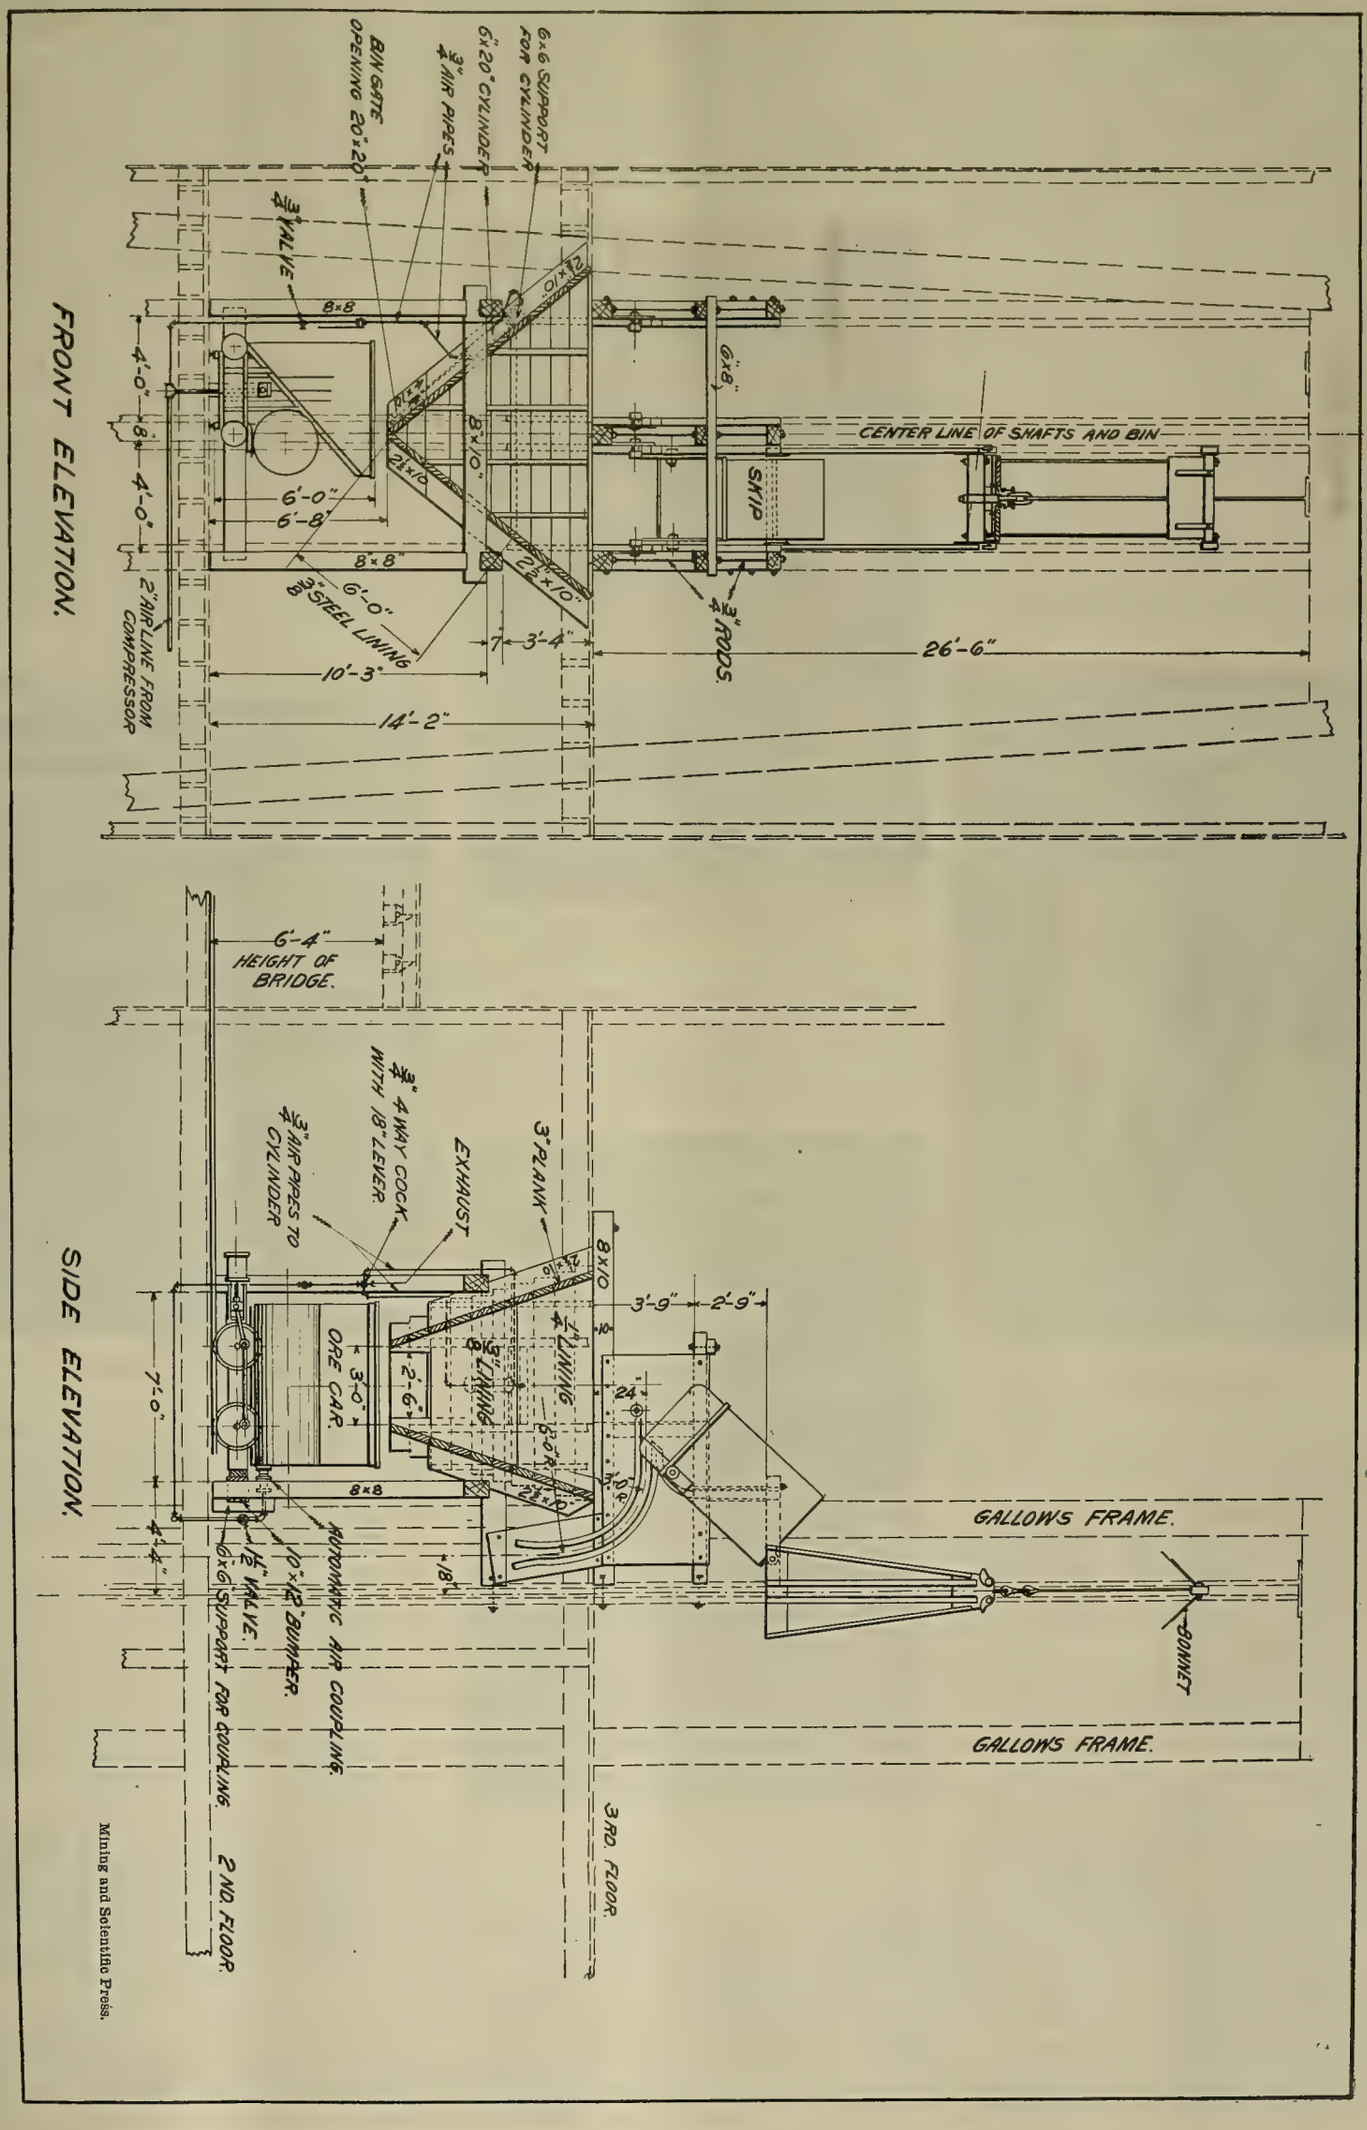
Electric Smelting of Iron Ore.

Recently extensive experiments have been made in electric smelting, particularly in Canada. At the Sault Ste. Marie, Prof. Haanel has been in charge of operations of this character. He lately telegraphed the Canadian Minister of the Interior as follows:

"Successful demonstration of all points stated in my memorandum on electric smelting of Canadian iron ores requiring investigation. Output greater than the figure adopted by Harbord in report of Commission. Successful smelting of magnetite and de-sulphurization of pig. Successful substitution of charcoal, and therefore of peat coke, for coke. Consumption of electrode insignificant. Production of nickel pig of fine quality from roasted pyrrhotite. Forty tons of pig have so far been produced. Process admits of immediate commercial application. Experiments will be completed in about two weeks."

(Sgd.) EUGENE HAANEL, Supt. of Mines.

IMPACT TESTS of steel are discussed at some length in *The Engineer*, of London, by Capt. Riall Sankey, who is of the opinion that they deserve more general attention than has been given to them. "The variation in the results obtained with the same steel," he says, "are undoubtedly considerable in any case, and are apt to scandalize those who are accustomed to quote tensile tests to the first or second place of decimals. The writer is not prepared at present to give any reason for these variations; but he knows that, notwithstanding them, those who have made a sufficient number of impact tests are prepared to rely on them as being a good guide to the quality of steel." This opinion is in line with the general belief of American engineers who have studied such tests carefully.



ARRANGEMENT FOR HANDLING ORE. GOLDEN CYCLE MINE, CRIPPLE CREEK, COLORADO.

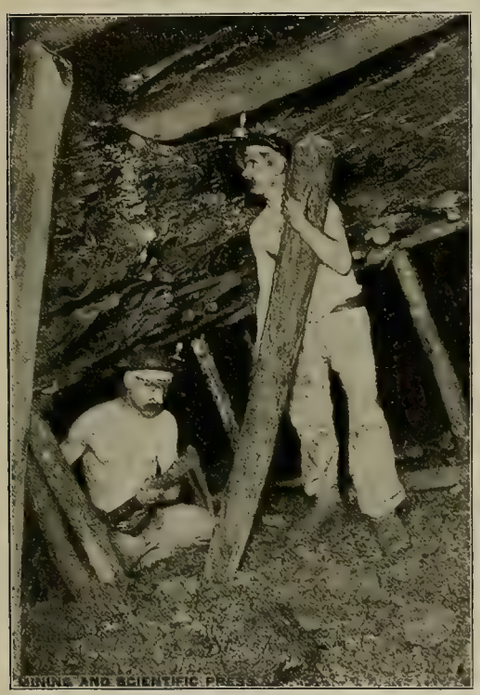
The Coal Disaster in France.

Written for the MINING AND SCIENTIFIC PRESS by DONALD F. CAMPBELL.

To one who is intimately acquainted with the Pas de Calais coalfield the news of the recent appalling disaster has its horror increased by its unexpectedness. The adjoining Belgian coalfield, which is now being worked at a depth of 4,000 ft., has always been notorious for its fiery nature, but hitherto the Pas de Calais has proudly boasted of the lowest mortality of the world's great producers.

The most striking feature which appeals to the engineer visiting this district is perhaps the lavish way in which the mines are equipped. On first approaching one of these large pits, the high walls and heavy gates tell at once of the frequent strikes and the substantial means adopted for the protection of the splendid machinery and structures.

When once inside the company's sacred precincts the cleanliness of the yards, the substantial nature of all the buildings and the enclosed pithead frames cannot but strike the visitor as remarkable. The universal use of flat, tapered hemp ropes and the descent in three and four-deckers cramped in little mine-cars will be a novel experience. The sumptuous surroundings here far excel the older Belgian coal basin which is situated a little further east. It



Timbering a Coal Face.

is indeed difficult to imagine how this terrible accident could have occurred in such a district as this, where almost unlimited sums seem to be available for the highest grade of equipment, where the best educated and most experienced of French engineers vie with one another to attain the greatest state of efficiency, where each department is also under the control of a man especially trained in his particular branch of engineering; in such a community it seems almost impossible to conceive how so great a number of men could have been within the danger zone arising from any one catastrophe.

The most prominent feature of the mechanical equipment is the centralization of all machinery. Thus, for instance, it is customary to have one enormous engine-room in which the hoisting-engine, fan-engines, compressors, and electric generators are placed.

Steam is generally used for the hoists, which are often over 2,000 h.p. The necessity for highly efficient engines will easily be recognized when it is remembered that one company alone is handling an output of three million tons per annum, and the whole of this is raised in small cars carrying less than half a ton apiece. From these great central stations three-phase generators distribute power to outlying pits, where it is usually transformed by static transformers and used for a variety of purposes. The compressors attain to a high state of efficiency and two or three-stage compression is the common practice, a splendid system for governing these great compressors being in vogue.

Ventilation is carried to an unusual degree of perfection, though in this department the French can not rival American practice. The commonest type of fan in this district is one of high speed driven by a steam-engine, and the whole plant is duplicated, the units being operated each alternate month.

In this remarkable coalfield the highest possible values are extracted from the mineral and the sale of coal is by no means the only source of revenue to the wealthy companies. Coke and the valuable by-products which are produced in its manufacture find an excellent market in the neighboring iron-producing districts and the great chemical works of

Women Preparing the Safety Lamps.

Germany. The coke ovens are usually equipped with regenerators, and the gas, having had all its values extracted in an extensive condensing plant under the supervision of experienced chemists, is thus utilized for the coke-ovens, any available excess being employed for raising steam. The manufacture of

Dinner Time Underground.

aniline dyes and other finished chemicals is not carried out on the spot; the majority of the products are shipped to the chemical works in the raw state and constitute a valuable source of revenue.

Economy of transport has received much attention and canals are more extensively employed in this district than in any other part of the world. The network of waterways connects with all the principal industrial centers of Belgium and France. Many of these are covered with strings of barges towed by electric trolley motors, which are said to be economical and satisfactory. The loading of these barges is accomplished with remarkable rapidity by methods which compare favorably with those of Barry docks and other European coal centers.

This coal basin is full of interest alike to the miner and to the geologist, for it possesses many peculiarities. The thickness of the seams which are now being extracted varies from less than half a meter to about a meter and a quarter, though it is not uncommon to find considerable masses of coal where extensive folding occurs in the seams. The high inclination and its variation make it necessary to adopt special methods to suit conditions, and some of these are very ingenious. The tiny mine-cars, sometimes built aslant to suit the inclination of the seam, and the forests of slender poles used to support these narrow excavations, are unlike those seen in any other district. The accompanying photographs will illustrate.

The geology, too, is interesting, and presented some surprises to early investigators, for the coal seams peculiar to the Carboniferous rocks were found to occur under strata of Devonian age. This apparent anomaly has, however, been satisfactorily explained by recent developments, and it can clearly be seen that the super-position of the older Devonian rocks is due to a great fold in the formation.

The tardy development of this great coal basin, for it is still in its infancy, is largely due to the fact that the seams are overlain by a considerable thickness of calcareous marls, which have not only concealed the treasures beneath it, but have rendered their exploitation a matter of difficulty and expense.

Safety Chain at the Top of an Incline.

These barren measures carry enormous quantities of water and quicksand, in consequence of which special methods have to be adopted in sinking. The practice of freezing the ground with ammonia, by means of a number of holes around the site of the shaft, is generally selected and is successful, as the thickness of these water-bearing beds is not excessive.

To every miner, and especially to those acquainted with this locality, the extremely hazardous nature of his calling, and the uncertainty of what he may be pleased to consider satisfactory working conditions, will be deeply impressed on his mind when he reads of the occurrence of such an appalling disaster in one of the most progressive mining districts of Europe; while the engineer will be at an entire loss to understand how an explosion could affect so extensive an area in a mine where a high standard of engineering and organization is maintained.

SOME assayers in Colorado add fluorspar to the flux for Cripple Creek ores. They state that they obtain higher results in that way. The statement is made that fluorspar goes through a smelting furnace unchanged, and certain smelters will not pay for the lime content of fluorspar as 'available lime.' This is, however, erroneous. Fluorspar is a powerful flux, and its addition to the assay charge may possibly lead to higher results because of the production of a better slag.

ERRATUM.—THE article on 'Thorium' appearing on page 145 of our issue of March 3 was taken from the editorial column of the *Mining Journal*, London. Acknowledgment was omitted through an oversight. —EDITOR.

The Grand Central-Mammoth Decision.

(*Continued from Page 160.*)

In determining whether the findings of the court were warranted by the evidence, it is important to consider what constitutes a vein or lode. It will hardly be contended that, merely because rock is broken, crushed, shattered, and even fissured, it constitutes a vein within the meaning of the laws of Congress. All miners of any experience, as well as men of scientific research, know that such occurrences may be found in the most barren country. Something more is necessary to dignify that kind of material with the character of a vein or lode. The material, whatever else may be its condition, must be metalliferous—must contain some kind of mineral of value, so as to distinguish it from the country rock; and especially is this true where there are no well-defined walls.

Fissure veins have many characteristics. They are the fillings of fissures or openings in the country rock; they contain different kinds of material, in some respects corresponding with, in others differing from, the country rock; the most common material being quartz. The fissures have selvages and slickensides, and the gangue material is generally easily distinguished from the country rock.

Fissure veins are simple or banded—some continue in the same direction, others are irregular and change their course—some have a continuity of ore while others are barren in places, and still others are faulted. The appellant, as we have seen from the testimony, claims the vein in dispute is continuous in the same direction; the respondent that it changes its course and is faulted. The books tell us that vein-making fissures have been formed, by contraction on drying, as in an argillaceous stratum, or on cooling from fusion, or from heat attending metamorphism; by subterranean movements, by the disruptive or expansive action of vapors resulting from volcanic action; and by corroding vapors, or by solutions from the deep which sometimes enlarge the fissure, especially where the rock is limestone. Fissures formed through volcanic action, and enlarged by corroding solutions and vapors, are deep-seated and frequently contain large cavities. That the vein in question was so formed by such action and solutions or vapors appears from the testimony, as we have already observed. It will be perceived that to define the word 'vein' that represents a thing of so many and varied characteristics is a matter attended with difficulty, especially is this true if such definition, in view of the statutes which deal with mineral-bearing veins only, is to convey an accurate idea of the thing itself. Mr. Justice Field, in the Eureka case, 4 Sawy. 302, said: "It is difficult to give any definition of the term as understood and used in the acts of Congress, which will not be subject to criticism. A fissure in the earth's crust, an opening in its rocks and strata made by some force of nature, in which the mineral is deposited, would seem to be essential to the definition of a lode, in the judgment of geologists. But to the practical miner the fissure and its walls are only of importance as indicating the boundaries within which he may look for and reasonably expect to find the ore he seeks. A continuous body of mineralized rock lying within any other well-defined boundaries on the earth's surface and under it, would equally constitute in his eyes, a lode. We are of opinion, therefore, that the term as used in the acts of Congress is applicable to any zone or belt of mineralized rock lying within the boundaries clearly separating it from the neighboring rock."

In Iron Silver Mining Co. *vs.* Cheesman, 116 U. S., 529, the Supreme Court of the United States adopted a definition of vein given by Mr. Justice Hallett in the same case, as follows: "To determine whether a lode or vein exists, it is necessary to define those terms; and as to that, it is enough to say that a lode or vein is a body of mineral, or mineral-bearing rock, within defined boundaries in the general mass of the mountain. In this definition the elements are the body of mineral or mineral-bearing rock and the boundaries; with either of these things well established, very slight evidence may be accepted as to the existence of the other. A body of mineral or mineral-bearing rock in the general mass of the mountain, so far as it may continue unbroken and without interruption, may be regarded as a lode, whatever the boundaries may be. In the existence of such body, and to the extent of it, boundaries are implied. On the other hand, with well-defined boundaries very slight evidence of ore within such boundaries will prove the existence of a lode. Such boundaries constitute a fissure, and if in such fissure ore is found, although at considerable intervals and in small quantities, it is called a lode or vein."

In all these definitions, as will be noticed, the essential elements of a vein are mineral or mineral-bearing rock and boundaries, and no doubt that, when one of these elements is well established, "very slight evidence may be accepted as to the existence of the other." It would seem, therefore, that where one claims extra-lateral rights, under the acts of Congress, because of a vein existing and apexing in his ground, but which has no well-defined boundaries, he, when his claim is controverted, must, in order to exercise such rights, show a body of mineral-bearing rock of such value as will distinguish it from the country rock, or from the general mass of the mountain. The material must in texture and value be such as to show the existence of a vein, and the mere fact, as has been stated, or proof of the fact that the rock is broken, shattered and fissured, and mixed with calcareous substance, though it may show a conglomerate mass, does not establish, in the sense of the statutes, a vein. When, however, the walls or boundaries are well-defined, the vein differentiated from the adjacent country, and the kind of material mentioned constitutes the filling, evidence of slight value in mineral will, it seems, be sufficient. It is insisted for the appellant, however, that "a lode, within the meaning of the statute, is whatever the miner can follow with a reasonable expectation of finding ore;" that, though he sees no ore, yet, if he sees gangue and vein-matter, he discovers the lode; and that whatever material would be sufficient to render valid a location thereon would be sufficient evidence of apex to justify one in following therefrom downward, beyond the side-lines of the location, in the same kind of material to, and beneath, the surface of his neighbor's property.

We do not thus interpret the law. What may constitute a sufficient discovery to warrant a location of a claim may be wholly inadequate to justify the locator in claiming or exercising any rights reserved by the statutes. What constitutes a discovery, that will validate a location, is a very different thing from what constitutes an apex to which attaches the statutory right to invade the possession of, and appropriate, the property which is presumed to belong to an adjoining owner. The question of a sufficient discovery of a vein, of the validity of a notice of location, upon which the cases, cited by the appellant on this point, are authority, is substantially different from one relating to the continuity of a vein on its dip from the apex, and which tests the rights of the undisputed owner of the surface to what lies underneath and within his own boundaries.

It is the object and policy of the law to encourage the prospector and miner in their efforts to discover the hidden treasures of the mountains, and, therefore, as between conflicting lode claimants, the law is liberally construed in favor of the senior location, but where one claims what, *prima facie*, belongs to his neighbor, because of an apex in the claimant's location, a more rigid rule of construction against the claimant prevails, and, as we have already observed, he has the burden to show not merely that the vein on its dip may include the orebodies in the adjoining ground, but that, in fact, it does so include them. Until he establishes such fact, beyond reasonable controversy, he has no rights outside his side-lines in another's ground. "In determining what constitutes such a discovery as will satisfy the law and form the basis of a valid mining location, we find, as in the case of the definition of the terms 'lode' or 'vein' that the tendency of the courts is toward marked liberality of construction where a question arises between two miners who have located claims upon the same lode, or within the same surface boundaries, and toward strict rules of interpretation when the miner asserts rights in property which either *prima facie* belongs to some one else or is claimed under laws other than those providing for the disposition of mineral lands, in which latter case the *relative* value of the tract is a matter directly in issue. The reason for this is obvious. In applying a liberal rule to one class of cases and a rigid rule to another, the courts justify their action upon the theory that the object of each section of the Revised Statutes, and the whole policy of the entire law, should not be overlooked."—(1 'Lindley on Mines,' 2nd Ed. Sec. 336). The Supreme Court of Montana, in Fitzgerald *vs.* Clark, 17 Mont. 100, observed: "When it is said that a location may be sustained by the discovery of mineral deposits of such value as to at least justify the exploration of the lode in the expectation of finding ore sufficiently valuable to work, it is a very different question from telling a jury that the geological fact of the continuity of the vein to a certain point may be determined by what a practical miner might do in looking for some hoped-for continuity."

Reverting to the characteristics of a vein, it appearing from the definitions above quoted that its filling must consist of a body of mineral-bearing rock, what value such material should contain is a matter not devoid of difficulty, and no standard of value applicable to all such cases has yet, and probably never will be devised. It must necessarily depend upon the characteristics of the district in which the vein is found, and upon the character, as to boundaries, of the vein itself. If the country rock, or the general mass of the mountain, outside of the limits of the vein, is wholly barren, slight values of the vein material, as before stated, would seem to satisfy the law, but if, on the other hand, the rock of the district generally carries values, then, undoubtedly, the values in the vein material, where the boundaries of the vein are not well, or not at all defined, either on the surface or at depth, should be in excess of those of the country rock; else there can be no line of demarcation, nor, where the rock is generally broken, shattered and fissured, anything to separate it from the adjacent country. Values, therefore, of the filling of a vein must be considered with special reference to the district where the vein is found. It is likewise as to a definition.

In Migeon *vs.* Montana Cent. Ry. Co. 77 Fed. 249, it was said: "The definition of a lode must always have special reference to the formation and peculiar characteristics of the particular district in which the lode or vein is found."

Now, weighing and considering the evidence, which we have already examined, in the light of the foregoing definitions, adopted and announced by the most eminent tribunal in this country, and bearing in mind the characteristics of a vein to which we have adverted, the conclusion seems inevitable that no vein, that will satisfy the demands of the law, has been shown to exist north of the north end of the Cunningham stope, or north of the Silveropolis south end-line extended, within the limits of Lot 38, which from its apex on its dip extends to and includes the orebodies in question.

It is true, the appellant claims the open-cuts and the workings at depth are substantially all in vein material; but, as we have seen,—in the judgment of the appellant's witnesses,—broken, shattered and fissured limestone, or crushed and brecciated matter, no matter how barren, constitutes vein material, although such matter and conditions exist, without any defined boundaries, many hundreds of feet to the east and west of Lot 38, in fact, throughout that limestone area, so far as it was examined by witnesses, and with no more mineralization than is contained in the general mass of the mountain for more than a thousand feet to the east and west, or through the limestone belt. Is it not difficult to perceive how such material, in the absence of both a hanging and foot-wall, can be regarded as a vein? Are not the essential characteristics of a vein absolutely wanting? In the absence of the very elements which constitute a vein, as defined by the highest court of our country, how can we hold a vein exists? There appears to be no mineralization in excess of that contained in the country rock; the existence of no body of mineral or mineral-bearing rock in any opening or fissure established. No witness, save Mr. Akers, attempted to locate the foot-wall of the vein, and he, as we have noticed, at but one place, in judgment only, for his evidence is not direct or satisfactory as to the fact. Several witnesses at a few points attempted to fix the hanging wall, but in each instance the testimony respecting it seems to point to an arbitrary location, for the fracturing, which they claim to be the limits of the vein, extends far to the west of the places pointed to as the hanging wall. We doubt if the most careful scrutiny of an expert could, from the description of the material in evidence, locate what in the judgment of those witnesses is the hanging wall. It seems to exist in opinion only. Nor does the fracturing stop at the Grand Central orebodies. It is shown in evidence to extend, at least as far west as the Grand Central shaft, more than a thousand feet beyond where that wall was attempted to be identified. No court would be justified in holding that, in such a formation as this, the limits of fracturing constitute the limits of the vein. Such a holding would be alike unreasonable and impracticable. It would convert practically all that whole limestone area into a vein—a vein thousands of feet wide, the like of which, we venture to say, no geologist or miner has ever known. Even if there be found an occasional vug or a fragment of ore, yet, where it is disconnected from any orebody and so intermingled with and surrounded by country rock that it cannot be regarded as continuous, it does not mark the line of a vein or lode, within the meaning of the law.

Upon very careful scrutiny of the evidence, we are of the opinion that the court did not err in rejecting the theory that the limits of fracturing constituted the limits of the vein, nor in holding that the vein, existing in the south end of Lot 38, did not continue in that lot north of the north end of the Cunningham stope. Where then, and in what direction, does the vein proceed on its strike from that stope, and where are its boundaries or limits? That the Mammoth vein was formed by replacement—by replacing the limestone, molecule for molecule, with mineral through the thermal and chemical waters, or corroding of vapors or solutions, ascending from the deep through the fissure or series of fissures constituting the lode, and that, where the ore appears, the fissure or opening was widened and large cavities created and filled with ore, through metasomatic action—appears manifest from the evidence. The acid and corrosive solutions acting upon the limestone corroded it or dissolved it, and the limestone thus precipitated the ore, by depositing it out of the solution. Thus, evidently, the orebodies were built up particle by particle by dissolving the limestone and precipitating the ore, or by replacing the limestone with ore. It appears in evidence that great masses of ore are found in which the original bedding planes can yet be traced, these planes not having been obliterated by the metasomatic change. It also appears in evidence, as has been observed, that, in running from an orebody into limestone anywhere, barren rock will be encountered within a few inches or a few feet of the ore. In other words, the limit of the ore everywhere is practically barren rock or barren material. This clearly appears from the testimony of Col. Wall and Mr. Loose. According to the decided weight of the evidence, the mineralization practically ceases everywhere within a short distance from the orebodies. The direction of the ore-channel and orebodies will readily be observed from the diagrams. It will be noticed that the ore-

channel, although irregular and changing its course at the Cunningham stope and at the Bradley-Consort line, is continuous clear through from the Mammoth shaft to north of the Butterfly stope, a distance of more than 2,000 feet.

Reverting to the geological features, we will first notice the dip of the vein and back fissure, and here the appellant in its contention encounters a serious obstacle, for, in vain will the record be searched for a degree of inclination that would carry a vein from Lot 38 to the orebodies in dispute. The vein and orebodies, wherever explored, occupy almost a vertical position. As we have shown by a review of the evidence, at the Mammoth shaft, the vein and ore go to the deep so nearly vertical that on the 1,900 level, a distance of 1,800 ft., the westing is but 100 ft., and the dip over 86° from the horizontal. The dip of the back fissure is shown to be about the same, from the Finn tunnel to the 800 level, a distance of 688 ft., the Finn tunnel being 92 ft., and the 800 level 135 west of the west side-line of Lot 38, making a westing of but 43 ft., and a dip of 86½°. So, we have seen, that, on the Grand Central side, from top of the winze on the 400 down to the 1,000 level, the dip is 82°, and that along the line U–T, where the orebodies in dispute occur, the dip is 75 to 80°. Now, considering the dip of the veins, as thus shown in both mines, in connection with the long distances, apparent from the surface maps, intervening between the west side-line of Lot 38 and the orebodies and vein on the Grand Central side, is it not clear without further demonstration that no dip is shown that could carry a vein from Lot 38 to the controverted orebodies and vein in the Grand Central mine? Such certainly seems to be the fact under proof.

It will be observed that the only place, where ore, in any considerable quantity, and unmistakable vein matter are found in connection with the dikes, is in the immediate vicinity of the ore-channel where it passes through them. Yet, if the appellant's theory that the vein passes through the Finn dike on its dip were well founded, we would expect to find evidences of it passing through it at other points along its strike.

It seems perfectly intelligible that when the mineral-bearing solutions, ascended from the deep and circulated through the main fissure or series of fissures, they were, by pressure or other of nature's processes, forced through the crushed and shattered rock and loose brecciated material, and that by the metasomatic action of the solutions, the mineral was deposited as far as the rock or material was thus physically prepared for the passage of those solutions. The evidence shows that the rock, at the junction of the dikes and where the vein passed through them, was so prepared, and this accounts for the strong mineralization in that vicinity, and for large orebodies, in places, like those of the Betsy and Klondike stopes, leading out from the main fissure or ore-channel.

We concur with witnesses in the criticism that the word 'dike' applied either to the Finn or Coates occurrence is not an appropriate term. It is an inappropriate name applied to what might, with propriety, be termed a faulting fracture. Those occurrences are not intrusions of igneous rocks or matter between sedimentary beds, characteristic of dikes, but, according to the testimony the fractures are filled with minute angular fragments of sedimentary bedrock — limestone and clay — brecciated material, in places, re-cemented with calcite. The term 'dike,' however, having been employed in the record and briefs, has been retained herein for convenience in referring to either of the fractures.

In places the particles composing the filling of the fractures are re-cemented, and in others the material is crushed and loose, especially so at, and in the vicinity of, the junction, and where the vein penetrates the breaks. Except where the ore-channel passes through them, the dikes are not mineralized. That they were originally formed—pre-mineral—and that there has been a faulting of the country along the Finn break, witnesses on both sides appear to agree. They also agree that there were subsequent movements which resulted in further crushing and grinding of the material of the dike, and in either raising the foot-wall country, along the course of the break, or dropping the hanging-wall country. There is a disagreement among the witnesses, however, as to whether the faulting occurred anterior or subsequent to the formation of the vein and orebodies. In the opinion of the witnesses for the respondent, the faulting occurred subsequent to the deposition of the mineral, and resulted in a dislocation and dropping of the orebodies, on the west side of the Finn dike, to a position, down anywhere to 400 ft., below that occupied before the faulting took place. There are indications disclosed by the testimony, however, that strongly tend to show that the throw, or possibly a succession of throws, were down and not up. Such are the indications where Mr. Tyler says ore, slight in quantity, was found in broken and shattered material, and had the appearance of having been dragged down from the orebodies above. Dr. Talmage says low-grade ore occurred at that station on the surface of fractured pieces of limestone, and that there is evidence of movement producing typical slickensides.

There is also testimony showing that, where the vein went through the dike, the ore was crushed, loose, oxidized and rarely re-cemented. Evidently the dike grew wider, and its material became more crushed and powdered, with each successive movement of the mountain masses along the original line of fracture, and the conditions shown by the evidence to exist fairly indicate, not only that faulting occurred along the line of break, since the deposition of mineral, but that the hanging-wall side, including the orebodies west of the dike, was successively dropped, thereby changing the relative elevations of the orebodies existing east and west of the dikes. The difference in the elevations of the orebodies would, likewise, be accounted for if the foot-wall country was raised, and the hanging-wall country not depressed. The importance of this most significant geological feature is thus apparent, for if the difference in the elevation of the orebodies be accounted for, by a depression of the hanging-wall or raising of the foot-wall country, and we think the conclusion, that one or the other of these throws occurred, is but a logical and reasonable deduction from the indications in evidence, then it is too clear for argument that no dip of a vein has been shown which could possibly extend from an apex in Mammoth ground, north of the Silveropolis south end-line extended, and intercept the orebodies in dispute.

Thus, upon careful review of the testimony and upon deliberate consideration of the main geological features, it seems clear that this great ore-channel was formed by the mineral solutions from the deep coursing through a fissure or series of fissures deflected from a northerly course at the Cunningham stope to a northwesterly course, and then again, near the Bradley-Consort line, to a more northerly course; that the channel and deposition of ore along its entire length resulted from the same processes of nature; that the vein passed through the dikes on its strike and was faulted; and that the orebodies in controversy are on its strike and not on its dip, and belong to the owners of the Silveropolis and Consort mining claims. It follows inevitably that the findings of the court were but proper deductions from the proof and being sustained by the great weight of the evidence, respecting both the surface and the underground workings, this judgment must be affirmed, unless there was an error in the refusal to permit the filing of the proposed amendment to the counter-claim, and the proposed original counter-claim, in each of which it was alleged that the vein departed from Lot 38 as found by the court, but that it passed into and continued at its apex and on its strike in the Golden King and Bradley mining claims. [This issue the court proceeds to decide in the negative.—EDITOR.]

Such seems to be the case at bar. The appellant, having founded its claim to the orebodies in its neighbor's ground, upon reserved or extra-lateral rights, has received no injury by its failure to establish a vein in its own ground which would warrant a recovery, and, therefore, cannot complain of the judgment against it, for it still owns all of its possessions. By this decree the appellant had been deprived of none of its property, although, if it has been successful, it would have acquired an immense fortune in its neighbor's land.

Union Shaft, Virginia City.

PROPERTIES OF PLATINUM.—Pure platinum is a silvery white metal with a specific gravity of 21.5. It is the heaviest metal occurring in nature, with the exception of iridosmine. It is almost as hard as iron and very malleable. Platinum does not amalgamate with quicksilver, is not dissolved by potassium cyanide when cold, and is not attacked by acids, except the mixture of nitric acid and hydrochloric acid, known as aqua regia. It is more difficult to melt than gold. Native platinum has been found most frequently in gold-bearing sands. On account of its weight it remains in the sluices with gold and other heavy material. Platinum is most readily distinguished as follows: (1) By its great weight —in panning it remains behind even gold in the pan; (2) its white color —it is whiter than lead and is distinguished from amalgam by its smooth surface, whereas the surface of amalgam, as seen under a good glass, is rough; (3) its resistance to nitric acid, as compared with native silver or lead. Native platinum is usually very impure; occasionally it contains so much iron chromite and other impurities as to be dark in color and not easily distinguished from grains of chromite with which it is frequently associated. It often contains iridosmine, which occurs as flat angular scales, while platinum grains are usually rounded like gold dust. Generally platinum grains are smaller than gold grains.—*U. S. Geological Survey.*

BLUESTONE (copper sulphate) is recovered in electrolytic copper process from the electrolyte by first boiling the solution in lead-lined tanks with cement copper, in the presence of steam and air, for the purpose of neutralizing any free acid present and to increase the percentage of copper present to the amount desired. It is then conveyed to the tanks, where the copper sulphate crystallizes out on strips of lead suspended in the saturated solution. The liquor remaining contains the greater part of the antimony and arsenic which may have been present in the electrolyte and a small amount of copper. The latter is recovered later in other tanks by precipitation on sheets of iron. The copper precipitates in these tanks first, and later the arsenic is thrown down. In some works the mother liquor remaining after recovery of the greater part of the bluestone is concentrated by evaporation, to crystallize out the remainder of the copper sulphate and the arsenious acid. The bluestone is then leached out with an amount of water just sufficient to dissolve it without dissolving the arsenious acid, or iron sulphate. These latter are recovered from the liquor remaining after the last of the copper sulphate has been secured.

THE retail prices of the higher grades of pure white and blue diamonds from the South African mines were again advanced 5% in London recently. Altogether there have been advances in the rough goods aggregating about 60% in four years, but some grades of stones have been put up even higher. The average value of the rough diamonds imported at New York last year was $37.50 a carat. The explanation of the advance given by the London diamond merchants is that there is a scarcity of the qualities of stones that are most in demand, and mining expenses are greater than formerly. This is not a fact, however. For several years there has been a steady fall in the cost of production. A better explanation of the continual advances in prices appears to be that the De Beers and Premier companies are working in harmony.

Modernizing the Comstock Lode.

Written for the MINING AND SCIENTIFIC PRESS by LEON M. HALL.

After many vicissitudes and years of patient toil, the plans for modernizing the Comstock Lode are assuming a definite shape and the end of all dead work is now in sight. Just how well these plans have matured cannot be better illustrated than by a brief description of the new Union shaft works and a comparison with the old.

The Union Shaft Company was a combination (of the Sierra Nevada, Union Consolidated and Mexican Mining Companies) for sinking and equipping what was formerly the North Consolidated Virginia shaft, in order to exploit a large consolidated area from a central opening. This shaft was one of the pet schemes of John W. Mackay and James G. Fair; here they erected and equipped what was at that time the finest and largest mining plant in the world.

The shaft was sunk to a depth of 2,750 ft. and about $2,500,000 was extracted therefrom. The main hoist consisted of a double direct-acting engine with 30 by 96-in. cylinders. The reels when full were about 16 ft. diam. and held 3,000 ft. of 8-in. flat rope. The pump-hoist consisted of a double 18 by 24-in. engine geared five to one, and this was used to handle the heavy pumping machinery. The pump was of the Cornish pattern and consisted of a double line of 18 by 120-in. plungers. These were operated by means of an Oregon pine pump-rod 20 in. square and 2,700 ft. long. The engine was compound-condensing, with cylinders 64 by 78 in. and 100 by 99 in. The flywheel was 36 ft. 1 in. diam. and weighed 115 tons. The steam plant consisted of 12 return-tube boilers 54 in. by 16 ft., arranged for burning wood. The consumption of fuel at the shaft was 60 cords per day, at an average cost of $11 per cord.

This shaft and machinery were operated until the mines became flooded in 1885; since that time operations have been carried on in a desultory manner until about a year and one-half ago, when the works were, unfortunately, consumed by fire. At the time of the fire, an effort was being made to repair the shaft and re-open the lower levels; this improvement was almost entirely lost at the time of the fire, inasmuch as the shaft was burned and caved to the 900-ft. level. It may be mentioned to the credit of the Union shaft management that this property has been entirely rehabilitated and put into first-class, modern condition without exceeding their regular monthly allowance.

The new works, as shown by the accompanying photographs, are arranged in the form of a cross and consist of three separate corrugated iron buildings and a steel head-frame of pleasing and economical design. The engine house is 36 by 62 by 20 ft. and contains, besides the 100-h.p. electric hoist, a 75-h.p. two-stage Ingersoll-Sergeant air compressor and all transformers, switches and meters. The electric hoist is of the balanced tail-rope type, with an auxiliary sinking-drum. It is speeded to 1,000 ft. per min. with single-deck cages, and has a capacity of about 500 tons per day from a depth of 2,000 ft. This hoist is in successful operation and I do not hesitate to say that in so far as speed, control, reliability and efficiency are concerned it is the most perfect mechanism of the kind I have ever seen. Accurate tests show an efficiency of over 72%, and when hoisting rock the brake is seldom used. The motor is a special 100-h.p., 460-volt General Electric variable-speed motor, operating at 450 rev. per min. The air compressor, a class J C, Ingersoll-Sergeant, 19¼ by 12 by 12 in., is driven by a 75-h.p., 2,000-volt, type C, Westinghouse motor, and is connected to the compressor by means of a Morse chain-drive. Three 40-kw., type H, General Electric transformers are used to transform the current from 2,240 to 460 volts for the hoist and for the other surface motors. These are placed at the west end of the engine-house, together with all meters and switchboards.

The carpenter shop, south of the shaft, is of corrugated iron and is 36 by 72 by 20 ft. This building contains the mine office and changing rooms. The carpenter shop is equipped with a 46-inch swing-saw driven by a 20-h.p. General Electric, type K, 440-volt motor. All mine-timbers are framed with this saw, so that carpenter help is reduced to a minimum. The blacksmith shop is directly north of the carpenter shop; it is of corrugated iron and is 26 by 40 by 14 ft. This shop is equipped with one forge, a 2-h.p. motor and American blower, besides a hand drill-press and bolt-cutter. All of these buildings are lighted by electricity and all wiring between them is carried in underground conduits. The steel head-frame was manufactured by the Wellman-Seaver-Morgan Company, and is of unusually pleasing design. This frame is 69 ft. high and is carried upon a 30 in. box girder 42 ft. long, the ends of it resting upon masonry walls on each side of the shaft. The struts are bolted to concrete foundations. The frame has withstood an 80-mile gale and snowstorm and vibrates very little under load. The shaft has been entirely re-timbered from the surface to the 900-ft. level, at which point the fire stopped. Below this point the shaft has been cleaned and repaired to the 2,050. We have, during the past month, opened a station on the 2,000-ft. level and have started a crosscut to intersect the vein now being opened on the 2,150 of the Consolidated Virginia and Ophir mines. This ore-body has already produced about $2,000,000 and as much more is likely to be extracted therefrom. A 4-in. compressed-air pipe extends from the surface to the 2,000-ft. level and a No. 4-3 conductor, 2,500 volt, steel-armored cable is used to transmit light and power to the underground workings. A metallic telephone circuit connects each building and the carman's station with all points in the shaft. A one-inch cold-water pipe extends from the 1,600-ft. level, the water to be used for drilling purposes. Three-inch Sergeant auxiliary-valve drills are used underground.

The plans for the entire plant were prepared by the writer and the works were erected under the superintendence of Mr. A. J. McDonnell.

Head-Frame at Union Shaft.

PURE NICKEL AND COBALT containing not more than 0.05% of iron and metallic impurities have the following physical properties when the metals are fused: Specific gravity at 15° C. (water at 4° C. = 1), cobalt = 8.8, nickel = 8.8. Hardness (Mohr's scale), cobalt = 5.5, nickel = 3 5. Melting point, cobalt = 1,530° C., nickel 1,470° C. Specific heat 20°–100° C. (water at 15° C. = 1), cobalt = 0.104, nickel = 0.108. Electric resistance at 0° C. (in Microhms-cm), cobalt = 5.5, nickel = 6.4. Coefficient of expansion 0°–20° C., cobalt = 0.0055, nickel = 0.0061. Breaking stress (kilo. per sq. mm.), cobalt = 50, nickel = 42.

Handling Ore in the Stopes.

By D. T. WILLIAMS.

The want of an efficient means of handling ore in the stopes is felt in all the mines on the Rand with the exception, perhaps, of the Randfontein group and the upper levels of the outcrop mines, which appear to have been favored by a kind Providence. The angle of dip at Randfontein averages about 60°, consequently no difficulty is experienced in moving ore from the stopes, and the only labor necessary is that required to clear the rock from the working faces to enable drilling operations to be resumed. Owing to this extreme angle the rock falls by gravity to the boxes or chutes at the foot of the stope, and the cost, therefore, is practically nil. But between this angle and, say, 10°, as it is in many mines, there is a wide range, and the relation between angle of dip and the cost of handling the ore becomes apparent at once.

The average cost of conveying rock from the working faces to the boxes at the foot of the stope is about 1s. 6d. per ton, and, should some device be introduced capable of, say, reducing this by 6d. per ton, it would represent a monthly saving of approximately £4 per stamp, an amount well worthy of attention.

The average angle of dip along the Reef varies between 10° and 40°, and it is in these mines where the greatest saving will be effected by efficient handling of the ore, especially in the flatter stopes, where the labor involved by shoveling is fully realized.

In designing an ore conveyor the following features are absolutely essential to ensure any degree of success, namely: Strength and durability; lightness of construction to facilitate handling; ease and rapidity with which it may be erected and dismantled; absence of loose parts, such as bolts, pins, etc., and minimum working parts.

Several devices containing some of these features have been introduced; the following are the best known:

Shaking chutes suspended from roof; stationary chutes; trucks operated in balance; trucks operated by winch; Henderson-Tucker aerial rope-gears; Tuchtan's shaking chute supported from ground; and the mono-rail.

Shaking or Swinging Chutes.—These have met with greater favor than any other form of mechanical conveyor yet introduced. A large number of the mines on the Rand have been equipped with these conveyors.

The shaking chute certainly possesses the essential feature of all successful ore-conveyors, namely, simplicity of construction and freedom from working parts, as it consists merely of a length of plate bent in the form of a trough and suspended from the hanging wall by chain slings. The chute is made up in sections, each about 15 ft. long; these may be removed readily from the stope to prevent injury during blasting operations, and are as readily re-erected.

The chief disadvantage of this ore conveyor is the difficulty of getting the holes drilled in line and properly spaced. When the hanging wall presents an irregular contour, some difficulty is experienced in getting the holes properly pitched, with the result that the suspension chains tend to pull against each other instead of producing a harmonious swinging motion. This difficulty is much more marked in narrow stopes, where the chains are comparatively short and where a few inches difference in the hanging-bolt centers seriously affects the swinging motion of the chutes. Another disadvantage is that each time it becomes necessary to remove the chute to another position in the stope, fresh holes have to be drilled in the hanging wall, and in many cases new hooks must be supplied.

Stationary Chute.—Between the angle of repose and that at which the ore will freely run by the aid of shoveling, stationary chutes are perhaps unequalled, but unfortunately it is here, and here only, they can meet with any favor. These chutes are similar to the shaking chute, with the exception, of course, that no chains are necessary, being merely laid upon the foot-wall. In stopes having a dip of about 30° and upward, the ore will not stick, provided it is handled perfectly dry and the chute free

from any wet fine, which materially affects the coefficient of friction.

The chutes are made in 10-ft. sections, and ⅛ in. thick, so that they may be conveniently handled, and each section is lapped over the lengths in advance and held by bolts passing through both chutes.

This kind of chute is efficient in stopes where the angle of dip is such that shaking chutes are unnecessary, and possesses the advantage of being the cheapest and simplest form yet introduced. Another decided advantage is the fact that these chutes need not be removed while blasting, as they can be protected from injury by merely piling up ore on either side, which of course may be allowed to remain until it becomes necessary to remove the chute to another part of the stope. The only disadvantage that may be placed against this system is its unsuitability for stopes having a dip of less than 30° or more than 40°, consequently it is available only within very narrow margin.

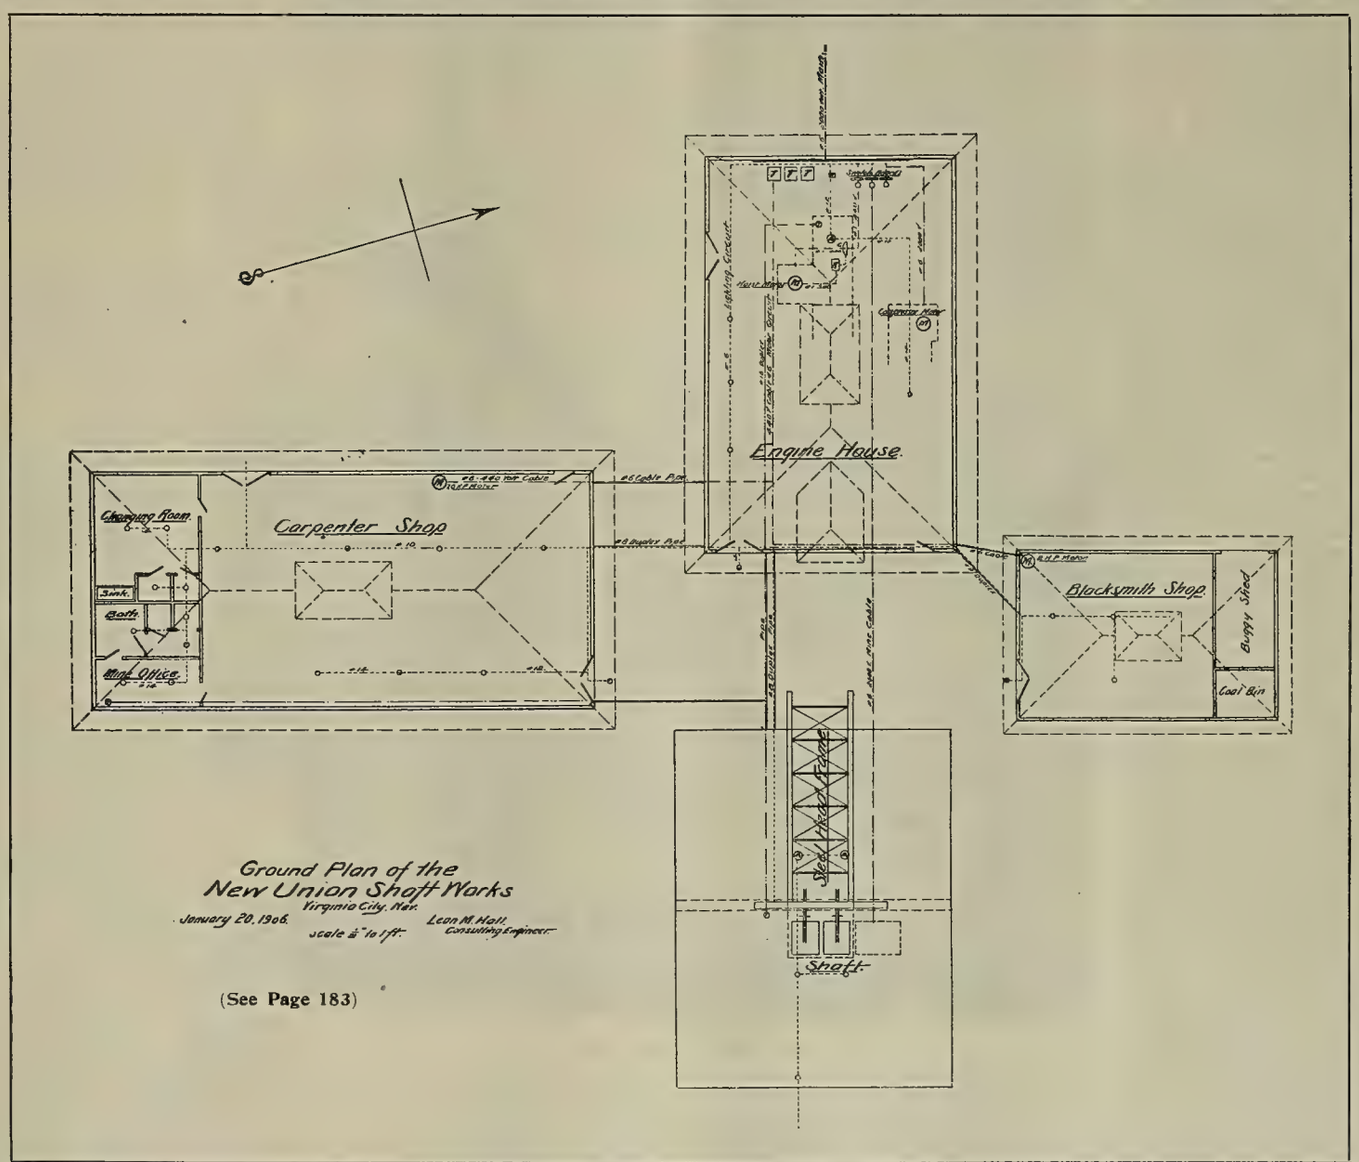
Truck Haulage.—This system has been tested on

The Henderson-Tucker Conveyor.—This is constructed upon the aerial-rope principle, and from the results obtained seems to have amply justified its introduction. The details of this gear are designed to meet the requirements of work in the stopes. The skip is carried upon a wire rope strained between two points, one of which is fixed over the stope-chute, the other being secured to an ordinary machine bar, which may be moved to any portion of the stope as required.

The loaded skip descends the stope by gravity and is hauled back to the loading point by means of a small winch clamped to the bar, and which may be operated by means of an air or electric motor or by hand-power. When the skip arrives at the loading point, it is held by means of a brake on the winch. On the completion of loading, the pressure on the brake is reduced and the skip allowed to descend at the highest possible speed consistent with safety.

This gear is suitable for stopes of any length and is equally efficient in long stopes as in short. When the adjoining section and is supported in the same way.

To compensate for irregularities in the foot-wall, adjustable lugs are fitted to the frame, so that no difficulty is experienced in securing perfect alignment. The U-hanger of the top section is fitted with a lever arm which is depressed by a boy; this provides the necessary swinging motion. In the top section there is a spring bumper which gives a sudden jerk to the chute and considerably increases its efficiency, especially in flat stopes; in fact this conveyor works with surprising results on perfectly level ground, and has practically settled the question for flat stopes. The whole gear has been most carefully and ingeniously designed, and all bolts, pins and working parts producing friction, carefully avoided. A distinguishing feature of the conveyor is its adaptability for working in narrow stopes, as it does not stand when erected complete more than 18 in. above ground-level, and with the exception of the stationary chute, would be capable of working in much narrower stopes than any gear yet introduced, in addition to the fact that



(See Page 183)

several mines with varying success, depending upon the conditions. The trucks used for this purpose are generally constructed somewhat shallower than the ordinary cocopan, but otherwise they are similar in design and of the same gauge.

The chief disadvantage of this system is that it is not practical in stopes of, say, less than 4 ft. 6 in. width, this being due to the fact that fully 18 in. is necessary above the top of the truck for loading purposes. The trucks are run upon ordinary rails of 12 to 14 lb. section, and are either operated by means of a winch at the top or foot of the stope, or run in balance with a brake-wheel at the top of the stope, the loaded car descending, and of course hauling the light car to the top for loading.

With the truck system, whether it be operated by a winch or run in balance, the chief advantage lies in the fact that no chutes are necessary at the foot of the stope, as the cars are run into the level either upon flat sheets or turntables, unhitched and taken to the main bins, where they are relieved of their contents and returned to the stope. Another advantage worthy of mention is that no time is occupied in erecting or dismantling the gear, as the cars are simply run out of the stope, and the rails suffer little or no damage if left in the stope during blasting operations.

span of the rope, however, exceeds, say, 100 ft., it becomes necessary to support the rope to prevent excessive sag. This is accomplished by means of jumper arms clamped to an ordinary machine bar. The tipping is accomplished automatically by means of a lug riveted on to the skip-body, and which comes in contact with a piece of piping arranged diagonally to the rope at the required dumping place. The necessary tension is given the rope by means of tighteners, one end of which is secured to the bar and the other to the rope. This gear may be dismantled in about 15 to 20 min., and erected in about 30 min., irrespective of the length of the stopes. Another advantage is the ease with which it may be moved from any one point in the stope to another; this operation only occupies, say, 10 to 15 minutes.

Tuchtan's Shaking Chute.—This is constructed substantially upon the principle of the swinging chute, but, instead of being suspended from the hanging wall, is supported in a frame made of a slight section of angle iron. It is made in lengths of 8 ft., and any one section can be easily handled by two boys. The chute is supported at the top end of each frame by means of a U-shaped hanger. The hanger is constructed of about ⅜-in. round iron, and the chute is fitted with two lugs which fit over this and form a bearing, the other end of the chute overlaps the it operates with efficiency in extremely flat stopes, and where the stationary chute would be useless. Another feature worthy of note is the ease with which it may be moved from any one position to another, as no holes have to be drilled for its support in the hanging wall. Unfortunately, no figures showing the saving effected by its use are obtainable, but during a trial it was proved that one boy was capable of doing ordinarily the work of six.

Cost.—The relation between the length of stopes and cost of handling ore is closely related, and forms a subject of considerable interest, although complex in nature. It is perfectly obvious to all that the cost of shoveling over a distance of, say, 220 ft., must be considerably higher than shoveling the same amount of ore over a distance of, say, 100 ft., presuming, of course, the angle of dip in each case to be the same.

At the Village Main Reef, with an average angle of dip of 29°, the stopes are only 150 ft. in length, whereas the Glen Deep, with an average angle of dip of 29°, are 230 ft. long. The comparison of cost is also marked, as the cost of conveying the ore from the working faces to the boxes on the Village Main Reef is only 1s. 2.75d. per ton, whereas the cost on the Glen Deep, with its 230-ft. stopes, is 1s. 6.45.*

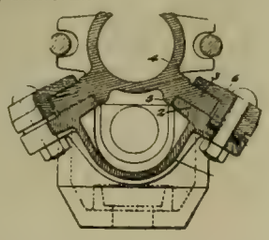
*From a paper read before the South African Association of Engineers.

Mining and Metallurgical Patents.

PATENTS ISSUED FEBRUARY 27, 1906.

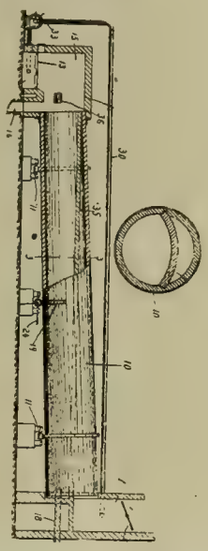
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

ROCK-DRILL.—No. 813,041; D. C. Demarest, Angels Camp, California.



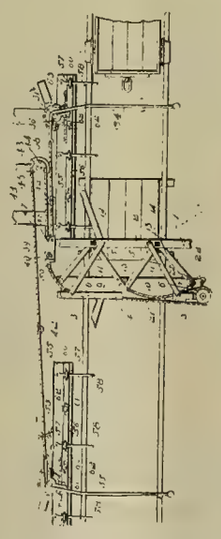
In rock-drilling machine combination of shell and cylinder supported thereon one of parts having lugs and the other part having seats for lugs, and means to clamp the cylinder to the shell, means including bolts passing through the caps and shell, shell having counterbores and caps having bosses fitting said counterbores.

OSCILLATING CEMENT-KILN.—No. 812,834; B. E. Eldred, Bronxville, New York.



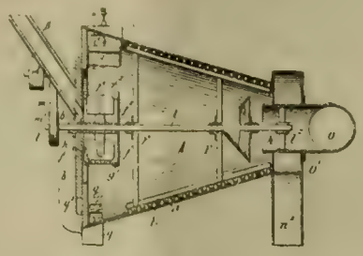
A cement-kiln having inclined barrel provided with flame-producing means at its lower end, and at its higher end a stack and material-supplying means, barrel having refractory interior walls forming combustion-chamber of flattened internal cross-section tapering from larger vertical diameter at lower end to a smaller vertical diameter at the stack end, and means for automatically rocking kiln.

MINE-SHAFT DOOR.—No. 813,067; I. Whitney, Oskaloosa, Iowa.



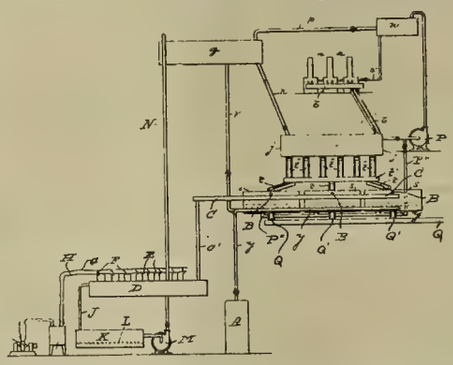
The combination with door, of a plurality of door-operating devices extending across pathway or road leading to the door, and in a position to be successively engaged by an animal or object traveling over track, each of door-operating devices serving when operated to effect complete opening movement of the door, and all acting as they are successively engaged to retain the door in full-open position.

SEPARATING-MACHINE.—No. 812,972; H. Baldwin, Youngstown, Ohio.



In machine for separating mixture of solid particles of different size or weight, combination of an imperforate tapering separating-chamber having near its small end an outlet for light or fine articles and near its large end an outlet for the heavy or coarse particles, circulating-fan arranged outside chamber and having its blast-orifice arranged to deliver the air-current into chamber near the large end and produce a whirling air-current therein, means for conducting the air-current from the interior of separating-chamber to circulating-fan, a fan for feeding material to be separated into air-current delivered into separating-chamber by circulating-fan, the case of feeding fan having peripheral wall by which the feeding-current is confined, and which is provided with a blast-orifice by which feeding-current is directed into current which is delivered by the circulating-fan, and means for feeding material to be separated to feeding-fan.

PROCESS OF EXTRACTING GOLD, SILVER, ETC.—No. 813,620; J. A. Comer, Los Angeles, California.

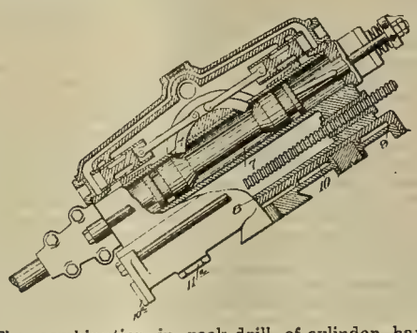


The process of extracting gold, silver, and other metals from ores, consisting in subjecting crushed ores to a solution of cyanide of potassium, drawing off the solution from pulp mixed therewith, impregnating with air the solution and sedimentary deposits suspended therein, separating sedimentary deposits from solution, and depositing metals contained in solution with electricity.

CONTAINER FOR FILTER-PRESSES. — No. 813,014; C. W. Merrill, Lead, South Dakota.

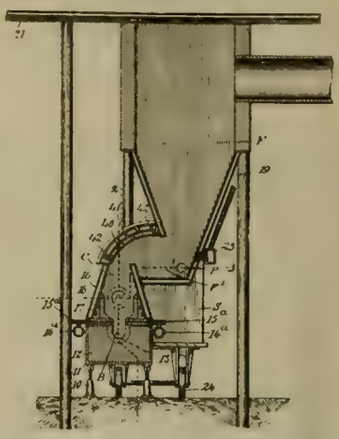
In a filter-press, a container provided with a wedge-shaped element along its inner surface; an inner surface in the form of a keystone, with the large end extending outward into the interior.

ROCK-DRILL.—No. 813,828; E. A. Rix, San Francisco, California.



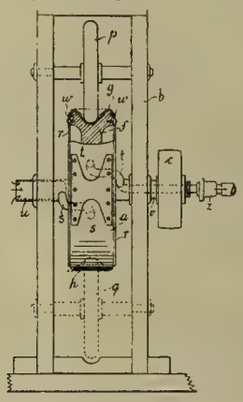
The combination in rock-drill, of cylinder, having slide fixed to and projecting from its bottom, shell within which slide is movable, bottom of slide and bottom of guide being spaced from each other, and means operable in space between bottoms and adjustable in one direction to compensate for wear between bottom and also sides of guide.

SMELTING AND REFINING PROCESS.—813,824; E. C. Pollard, Seattle, Washington.



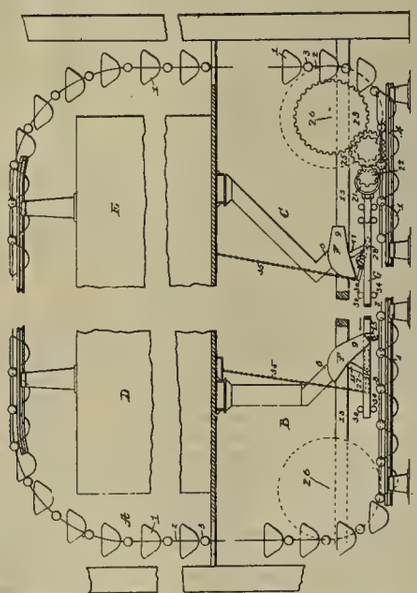
A continuous process of bessemerizing copper mattes, consisting in passing stream of silicious slag over bessemerizing regions, discharging slag into contact with ferrous sulphide to reduce any copper carried by slag to subsulphide, discharging a part of slag, and returning remainder thereof together with ferrous and cuprous sulphides, to bessemerizing regions to supply matte to bessemerizing regions.

COMPRESSOR. — No. 813,443; H. Mikorey, Schoneberg, near Berlin, Germany.



Compressor comprising wheel having groove on periphery, membrane formed of rubber stretched across groove so as to form an annular chamber, means for holding membrane at one point permanently pressed against bottom of chamber, an inlet-pipe entering chamber on one side of means, an outlet-pipe on other side thereof and roller of less thickness than wheel engaging membrane so as to force it against bottom of groove.

CONVEYER CHUTE.—No. 813,473; F. R. Willson, Jr., Worthington, Ohio.



In delivery or feed mechanism, combination of conduit for material having delivery opening, chute adapted to receive material from opening, a longitudinally reciprocating bar to which chute is connected whereby chute may be moved to deliver such received material, and a closing means for opening operated to cut off material from chute when latter is moved to deliver its material.

Mining Summary.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

Special Correspondence.

LONDON, February 28.

A company has just been formed—The Esperanza Copper and Sulphur Co., Ltd.—to exploit a group of mines in the province of Huelva, Spain, covering an area of 655 acres of mineralized ground, with surface rights over 1,900 acres, nearly the whole being purchased outright. The mines are connected with the port of Huelva by a railway 40 miles long. Messrs. Matheson & Son, of Rio Tinto fame, are the commercial agents. The prospectus is based on a report by Robert Addie, of Pringle & Addie. The capital is £350,000 in £1 shares with £100,000 of 5% debentures. Working capital £50,000, sufficient for an equipment to produce 100,000 tons of ore per annum, at which rate the life of the mine is estimated at 12 years at a profit of £70,000 per annum. Purchase price £381,500, payable in £100,000 debentures and the remainder in cash and fully paid shares. Leading copper firms guarantee the subscription of 185,000 shares. There are already developed, partly by mining and partly by open-cast: (1) 372,020 tons rich ore for export direct; (2) 584,337 tons poorer ore for local treatment; (3) 275,633 tons sulphur ore for sale direct. Estimated profit per ton: Class 1, mined, £1 7s 4d, open-cast £1; class 2, mined, 12s 6d, open-cast, 19s 6d. Class 3, mined and open cast, 3d. Total net profit at the mines from ore developed, £908,492, on basis of best selected copper at £63 per ton.

The Bonmahon Copper Mines Development Syndicate, Ltd., capital £30,000 in £1 shares, has been in operation for about three months re-opening the Knockmahon and Tankardstown copper mines in county Wicklow, Ireland. The rights have been acquired free from all royalty and charges. Working capital £12,500. The reports are by J. H. Collins and others. The management is under the direction of A. L. Pearse. The mines are expected to enter a highly remunerative stage within the next six months, and it is hoped that the opening up of these copper deposits will attract capital to Ireland.

It is expected that the new railway, with a port on the Red Sea, will have the result of directing attention to the extensive ancient goldfields of the Sudan (Ethiopia) between the Nile and the Red Sea. So far Egyptian mining in these modern times has not had a brilliant record. In a list of eleven companies operating in those regions of biblical interest, one only—the Egypt and Sudan Mining Co.—stands at a premium on the market. The Nile Valley Co., Ltd., after spending about £90,000, is appealing for more capital under a scheme of reconstruction. According to a shareholder's statement at the general meeting, they have only 'scratched' the ground to a depth of 200 ft. Recurrent rich patches have been found, but the average of the milling has been only 11 dwt. In regard to the aforesaid scheme, the proposed issue of partly paid shares by a new company as consideration for the property, with a liability of 4s. per share for working capital, has been pronounced *ultra vires* in the Court of Chancery. The decision that shareholders cannot be compelled to take up new shares with a liability under penalty of forfeiture and sale of their old shares is an important one, in view of the practice in numerous reconstructions which have taken place among English limited liability companies.

The shares of Torres Mines, Ltd., capital £100,000 in shares of 10s. each, have been introduced on the London market at 10s. 6d. to 11s. The company owns five claims near Parral, in Chihuahua, Mexico; area 28½ acres. The property was reported on by John Taylor & Sons. The lode is said to average 2½ ft. wide, value 33s. per ton without sorting, three-fifths being in gold. A considerable amount of development work. No prospectus published.

The January profit of Esperanza (Mexico) is reported as £63,542 against £86,258 in December. The falling off is attributed to a diminished output owing to shortage of railway cars for shipping ore, which forms the principal source of revenue.

At Camp Bird, the mill crushed in January 6,829 tons which yielded 7,920 oz. bullion, and about 489 tons concentrate. The profit on these returns is not stated. It is explained that the exact amounts realized by each month's production cannot be given within six weeks or two months, and as estimates are unsatisfactory, none are supplied. Instead of these, the total of the cash receipts for the month is shown, from which the working expenses for the same period are deducted, the difference being described as "applicable to profit." The problem as to what is the approximate monthly profit remains for solution on the completion of the accounts at the end of the financial year. There is no report as to the location and features of the developments—aggregating 709 ft.—during the month.

The annual meeting of the Tasmania Gold Mining Co., Ltd., held last week was an interesting function. Of the total capital of £500,000, the sum of £180,000 was originally set aside for working capital. The pumping installations are described as the most extensive and powerful machinery of the kind in the world—capacity 8,000,000 gal. per 24 hours from a depth of 2,000 ft. The plant includes three compound-horizontal pumping engines by Hathorn, Davey & Co., winding engine by Fraser & Chalmers, and numerous Babcock & Wilcox boilers. A new shaft 32 ft. 1 in. by 8 ft. 6 in. in the clear is being sunk to a depth of 1,250 ft.; present depth 900 ft. Ore reserves are put at 131,355 tons, of which 22,355 tons are blocked out. Gold sold during the year £130,442; average value of output £3 per ton, and average working costs £1 17s. 7d. per ton. Net profit £46,712. The former company paid dividends amounting to £750,000 from £2,000,000 worth of gold won at a moderate depth. Present developments include a length in ore of over 1,000 ft. at the 900-ft. level; width averages 6¾ ft. for an average value of nearly 1¾ oz. The lode has also been proved at the 1,000-ft. level for 191 ft. in ore, averaging 7¾ ft. wide and 1½ oz. per ton. The managers are John Taylor & Sons. As a proof of the interest taken in this company locally, it was stated at the meeting that two-thirds of the shareholders were in Australia.

Mt. Bischoff (Tasmania) tin mine has just declared a dividend of 10s., bringing the total of dividends paid to £2,031,000 or £167 5s. per share.

The latest valuation of the ore reserves of the Great Fingall Consolidated (West Australia), made by the general manager, puts the quantity at 753,042 tons of an average value of £2 15s. 6d. per ton.

The recently established Zinc Corporation, Ltd., with a capital of £350,000, has secured from Block 10 Co. Southern Broken Hill, Block 14 and British Broken Hill Proprietary, an aggregate of 1,750,000 tons of tailing, estimated to be worth £10,000,000 in zinc, lead and silver. The result of the mill (first unit) test has just been announced as satisfactory. The assays give 42% zinc, 8% lead and 15 oz. silver.

The New Zealand gold output for 1905 is given as £1,065,382, being an increase of £190,000 over 1904. Of this Waihi is estimated to have contributed £712,066, from which it paid dividends during the year amounting to £325,000. The yield for the last two years averaged £2 6s. per ton. The issued catipal of this famous company is £495,907. The gold taken out of the mine has amounted to £4,000,000. It is reported that the main Martha lode strengthens at depth.

The annual report of the Mysore Gold Mining Co., Ltd. (India), for 1905 is good reading. 195,650 tons were crushed for 184,957 oz. and 20,432 oz. from cyanidation of the tailing. Total value £804,660—a new record. Dividends paid for the year £420,500. Average yield from mill 18 dwt. 20 gr. and from tailing 2 dwt. 11 gr. The lode at the 3,226-ft. level is reported as three feet wide for 2 oz. 3 gr. per ton. Since the commencement of mining in 1884, the total value of gold extracted is £8,308,218, of which over a half has been paid to the shareholders as dividends.

As a striking contrast, the Coromandel Gold Mining Co. of India, Ltd., capital £135,000, has proved a prolonged disappointment. There have been three reconstructions of this company, the assessments totalling 17s. 6d. per share. Altogether £300,000 worth of gold has been won. The small balance of working capital remaining is being expended in searching for a lode supposed to extend from the neighboring Tank Block property at the southern end of the Coromandel mine.

The under-secretary for the colonies has declared that no Chinese contract expires till May, 1907, and that the Government does not propose to cancel the clause in the ordinance allowing coolies to re-engage for three years. He also states that to classify the conditions of Chinese labor in the Transvaal as "slavery" is a "terminological inexactitude." Winston Churchill is now followed by his chief, Lord Elgin, who "deeply regrets" the "tainted with slavery" speech of the Premier. These epithets, having served the electioneering hour, are to be dropped. Out of the hurly-burly of Parliamentary tongue-wagging emerges the Government "intention" not to allow any Asiatic race to enter the Transvaal again save as men free to live and labor in the country as they choose. Under responsible Government it is thought, in some quarters, that the mine owners will not be able to maintain their monopoly of power. The specter of a United South African republic once more threatens to trouble the councils of Downing street. Meantime the 200,000 to 300,000 "rascally shareholders" in South African mining have seen their securities fall in value during the last two months by over £21,000,000. It is said the liquidation is due largely to bankers calling in loans on these shares.

CLIFTON, ARIZ., March 10.

Within the last few weeks a great deal of interest, or rather re-interest, has arisen in gold mining in the Copper Mountain district, more especially in Gold gulch, where years ago many placer claims were worked profitably. A number of owners of promising gold claims in this district have pooled their interests, formed companies and placed stock on the market, which is being taken up by local people. Among these are the Gold Belt Development and Reduction Co. and the Arizona Gold Mining Co. These claims have not been merely scratched over, but have a large amount of work done on them, and are showing bodies of free-milling ore, which, when panned, gives liberal colors. Parties from Clifton and Morenci visit these claims every Sunday, and they seem to think highly of the property.

The farmers of the Gila valley, as well as the mining companies of this district, which operate concentrators, are much interested in the paper on 'Tailings—Its Effect on Irrigated Arable Land,' read by Prof. Forbes, of the University of Arizona, before a gathering of the farmers of the Gila valley recently. Notwithstanding all previous claims to the contrary, Prof. Forbes says that tailings, if properly handled, are beneficial to irrigated land. Mr. Forbes is considered as one of the highest authorities on irrigating waters, and his statements will have some weight, it is to be hoped, in reforming the opinions of the Gila valley farmers and help to down the bugaboo of a lawsuit against the three companies operating concentrators in this district.

Mr. Campbell, of Boston, manager of the Chase Creek Copper Co., was in Clifton recently visiting the mines of that company, and expressed himself as well pleased with the progress being made in the work by Superintendent Campbell. The main tunnel is now in over 1,200 ft., with a depth at the face of about 700 ft., and several veins have been cut. The object of this company is to drive until they reach the Longfellow lode, and, until this is done, they will ship little, if any, ore. But when shipment does commence, it is expected this company will be one of the large producers of the district.

The wagon-road from the Home Copper Co.'s claims to their shipping point on the Morenci Southern Railway, at Morenci, has been completed, and the new machinery is now on the way to be installed. The Home Copper Co. managers are preparing for the development of their property, and, while they do not expect to ship during the present year, the development work now being done will put them in shape to receive returns from the ore on the dumps.

The Detroit Copper Mining Co., of Arizona, at Morenci, has completed their power-line to the Santa Rosa group, at Metcalf, which they have purchased, and the work of installing hoists, ventilator fans, drills, etc., will be commenced at once. With the completion of the railroad, which this company is building from the Morenci Southern Railway at Frisco Pump to connect with the Coronado Railway at the Shannon Copper Co. smelter, the line of transportation will have been completed, and ore will be shipped steadily from the Santa Rosa copper mines for treatment at the Detroit Copper Co.'s smelter at Morenci.

Reports from the Mayflower copper district, adjoining the Copper Mountain district, are encouraging for the development of small holdings in that district. Several of these have been pooled, the owners having formed a syndicate of local capitalists to push development. This method of business seems to be coming into favor all over this district, as holders of copper claims in Gold gulch, Copper Mountain district, three miles from Morenci, have also adopted the same plan.

Concentrator No. 6, the new mill being erected by the Arizona Copper Co. at Morenci, is under way. Most of the steel framework is up, and a large part of the machinery installed. This concentrator is to treat the low-grade ore of the Humboldt and Joy mines, properties of the Arizona Copper Co. With the completion of this mill, Morenci will have three large concentrators in operation. At present the constructing force of this mill consists of 175 men. The work is under the direction of C. D. Clark.

TORONTO, March 10.

Extensive railroad construction is likely to be a prominent factor in promoting the development of mineral deposits, which have remained unexploited owing to the lack of transport. This is especially the case in regard to iron mines, as, owing to the approaching exhaustion of some of the Lake Superior deposits of high-grade ore, manufacturers will have to look to other sources, and ranges which were formerly considered too low grade will come into favor. The Moose Mountains or Hutton Township range, lying 25 miles north of Sudbury, is to be opened up, Mackenzie & Mann, who control the James Bay Railway, now in course of construction, having acquired an interest in it. The James Bay road is being built as a portion of the Northern Railway system, and the charter gives the company power to extend it as far as Hudson Bay. It was intended, however, to make Sudbury the northern terminus for some time, but in order to connect with the iron mines, it will be pushed 25 miles further north. A branch line will also be constructed, from a point near French river to the Georgian Bay, to allow of the shipment of ore by water. The ore is magnetite of a hard, crystalline character, containing a very small percentage of sulphur and no titanium. It varies from lean to high grade, but a considerable proportion carries iron to 58 or 60%. The railroad extensions are to be completed by January 1, 1907, and a large force is being put on at the mine to take out ore in readiness for shipment.

Dr. Haanel, Canadian Superintendent of Mines, who is at Sault Ste. Marie, directing the experiments in electric smelting which are being made by Dr. Herault, the French expert, sent this week a highly satisfactory report to the Department of the Interior. He stated that the demonstration had been successful in showing that magnetite as well as hematite ores could be economically smelted by the electric process and pig iron desulphurized; also that charcoal, and therefore peat, could be successfully substituted for coke. Nickel pig of fine quality had been produced from pyrrhotite. So far 40 tons of pig have been produced. The experiments will continue for about 10 days longer. Dr. Haanel declares that the process admits of immediate commercial application. The enormous importance to Canada of such a result is everywhere conceded, as it would render available great iron ore deposits, the distance of which from fuel supplies prevents their being utilized by present methods of smelting. But while the experiments are being watched with much interest by those concerned in mining and metallurgy, the general opinion among iron and steel manufacturers is that the electric process cannot compete economically with that now in use.

DENVER, March 10.

At the annual meeting of the Animas Power & Water Co., held on the 6th inst., at Colorado Springs, Henry Jameson, of Indianapolis, was elected president. Henry Hine, of Colorado Springs, under whose determined and progressive spirit the present development of the power plant has been accomplished, is retained as general manager. The company has been fully financed and it is not likely that it will again be hampered or its plans further retarded by lack of funds. This enterprise is destined to play an important part in the future development of the San Juan country, reducing, as it will, within the reach of all, the cost of power for mining and its collateral branches, thus making it possible to mine and market low-grade ores not now exploited. The liveliest center of activity in the San Juan country is the locality adjacent to Animas Forks. To that point the Animas Power & Water Co. first constructed its transmission lines.

It is noteworthy that after the lapse of 30 years Animas Forks, then (1876) a wide-awake mining town of 400 or 500 inhabitants, afterward entirely depopulated, should again be revived, and become an active, thriving center, and there is real justification for its existence now. Instead of the Eclipse smelter of 1880, built by James Cherry at the mouth of Grouse gulch, and written down as a costly failure, Animas Forks has the $500,000 concentrating mill of the Gold Prince mines, which will go into commission this season, and several other tributary mills.

The 1,000-ft. Bonanza tunnel, situated west of Animas Forks, is said to have cost from $300 to $400 per foot, under the early methods, but today mining can be done as cheaply as anywhere in the San Juan country; the advent of the power company promises to further reduce the cost of power from one-third to one-half.

The Mountain Queen mine, at the head of California gulch, near Animas Forks, probably the first property in the locality to send ore to a smelter—in the year

1877—was purchased last fall by Cripple Creek people led by Austin T. Holman, manager of the Golden Cycle. A machine-drill plant was installed and development work has been steadily prosecuted.

San Miguel county has been rather slow in recovering from the disarrangement of her industrial conditions, caused by the labor troubles of three or four years ago. However, recent progress has been steady, so that now the county has almost regained lost ground. Lessees at the Smuggler-Union mines have opened up fine bodies of ore in the lower workings. The Liberty Bell is encountering richer ore as development proceeds in greater depth. There are a number of new mills to be erected this season. The Japan mines are under working option and will be operated by lessees pending a deal. The lime contact below the town of Telluride will receive more than usual attention this summer from those who believe it a promising field for exploration.

At Cripple Creek, since securing the Burnside lease of the Laoconing mine, A. E. Carlton and John H. Hobbs have employed a force re-timbering the shaft and making other improvements preliminary to extracting the ore uncovered by Burnside. —— The lessees on the Gold Sovereign mine have opened new and seemingly extensive ore shoots in old ground north of the shaft.

SALT LAKE CITY, March 12.

Stockholders of the Copper Glance mine, in Bingham, have ratified negotiations for sale of the property to parties represented by John W. Burton, of Salt Lake, for $150,000. The property has been under examination during the past ten days.

The Bullion-Beck & Champion Mining Co. have authorized extending the life of the corporation 25 years. The property is in Tintic district.

The property of the Bingham Central Mining Co. has been under examination the past ten days by W. C. Dunham, of Los Angeles, and others, in the interests of prospective buyers of bonds recently authorized by the owners.

The New England Gold & Copper Co., at Bingham, is preparing for a more extensive campaign. Not long ago E. E. Abercrombie of Boston became identified with the company and was chosen vice-president and managing director. It is to be equipped with a compressor and a larger boarding-house. A 40-ton mill has been in operation for over a year, and the proceeds from the sale of concentrate have more than paid operating expenses, leaving the proceeds of ore sales as profit. Henry M. Adkinson, in charge of development the past two years, is general manager. The property is situated in the upper part of the camp adjoining the Boston Consolidated.

Negotiations are pending for merging the Utah Copper and Boston Consolidated mines at Bingham, and a company formed to operate them. The chief officials of the American Smelting & Refining Co. are at Salt Lake, which has acquired control of the Utah Copper. In the party are Daniel Guggenheim, S. R. Guggenheim, John Hays Hammond, Silas W. Eccles, vice-president and traffic manager, and Isaac Untermeyer, who, with D. C. Jackling, general manager of the Utah Copper, representing the interests of the latter corporation, while Samuel Newhouse, Lafayette Hanchett, and Louis S. Cates, manager of the Boston Consolidated, are attending to the interests of the Boston Consolidated and Cactus. The Guggenheim party will inspect the American smelters, at Murray, Utah, also that now under construction at Garfield.

Thomas F. Cole, of Duluth, the big mining operator, spent two days last week at the Silver King mine, at Park City, with Walter Fitch, his representative in this State.

For several weeks the examination of witnesses has been in progress in the smelter-smoke cases. The hearings may continue for several weeks. There is little doubt of a long siege of litigation with farmers and land owners in the vicinity of the smelters on one side, and the smelting companies on the other.

Daniel Guggenheim, president of the American Smelting & Refining Company and American Smelters' Securities Corporation, stated to the writer, on his arrival in Salt Lake, on the 10th inst., that the Securities Corporation had control of the Balaklala copper mine in Shasta county, California, and that the ores from that property would be sent to the smelter to be erected at San Francisco.

The St. Louis-Magnolia Mining Co. has been formed to operate the St. Louis-Magnolia and June Bug groups at Park City. James McGregor, of Salt Lake, is president and manager.

The Western Exploration Co. will open a branch office in Chicago.

At the Cactus properties in Beaver county a steam shovel is employed in stripping the surface which, Manager Hanchett says, is from 20 to 30 ft. deep. It will be three weeks before the shovel will be working on ore.

A total of 132 cars of ore were shipped to the Salt Lake smelters from the Tintic district last week, the shippers being: Ajax, 3; Bullion-Beck, 5; Beack Tunnel, 8; Centennial Eureka, 54; Dragon Iron, 5; Eagle & Blue Bell, 5; Eureka Hill, 6; Gemini, 10; Grand Central, 3; Lower Mammoth, 2; Mammoth, 9; May Day, 2; Ridge & Valley, 5; Scranton, 2; Swansea, 2; South Swansea, 1; Uncle Sam, crude, 3; concentrate, 2; Victoria, 3; Yankee Consolidated, 2.

ALASKA.

J. H. Rogers, traffic manager of the White Pass & Yukon Railway, states that his company has contracted to take in machinery for dredges, steam shovels and railway equipment to Dawson for the Guggenheims of New York.

The Detroit-Canadian-Klondike Co., which operated a dredge in the Yukon district last year, will instal another this year. —— A St. Louis company operating on Bonanza creek will put in a dredge this season. —— It is reported that a Toronto company will operate a dredge at Forty Mile this year.

W. C. Crosby and others, of Boston, have purchased the Dora Ebner and Mount Juneau mines at Juneau, and will take possession of the property April 1. The Hile tunnel will be extended to 3,000 ft., with a raise of 1,800 ft. A long tunnel will be driven on the Dora group. A lower tunnel will be driven from Gold creek to tap the orebodies at a greater depth, and a 100-stamp mill will be put in. It is planned to enlarge the latter later. Power for operating the mill will be generated on Salmon creek. The groups of mines taken over include 38 claims.

The steamer *Leelanaw*, which arrived at Tacoma last week with 1,000 tons of concentrates from the Treadwell mine, Douglas island, will return with a load of coal for the Treadwell plant.

The steamer *Farallon*, which arrived at Tacoma a few days ago with 125 tons of copper from Ellemar mines, near Valdez, will return with 250 tons of coal.

It was reported that P. Monohan and J. Smith have made a strike on the Upper Shushutna, near Seward, taking out 118 oz. gold in two days with a rocker.

E. W. Johnson of Seattle reports a rich strike on one of his Nome claims, the pay-streak running $400 to a pan. The claim is No. 8 on Cooper gulch, and is near the Portland beach property, from which $1,000,000 was taken last year. Captain Johnson believes they are on the same pay-streak. Johnson's Nome manager has taken three boilers which were being used for harbor improvements at Nome for work on the new diggings. Bedrock was struck at a depth of 65 ft. The crew on the property consists of 20 men, and three shifts are being worked.

ARIZONA.

Cochise County.

At the T. C. M. Co. mill, at Tombstone, everything is going satisfactorily. The run on 20 of the stamps since the mill started up has given good results, and has averaged 100 tons daily. It is reported that the remaining 20 stamps will shortly be operated on concentrating ore. At the big shaft the Dow pump has been installed at the 700-ft. level and two sinkers are expected here next week. The pumping record is kept at about 3,000,000 gal. daily, until such time as all pumps will be in commission, when this amount will be increased somewhat and sinking operations resumed. The output from the outlying mines of the company continues about the same, averaging a shipment of two carloads daily to the smelters.

Gila County.

Development work is to be done by the Apache Consolidated Mining Co. at the Basin mines, near Globe. E. F. Pfister, formerly with the Junction Co., at Bisbee, who has been made general manager, will sink a double-compartment shaft several hundred feet.

Maricopa County.

Contractor Mitchell has suspended diamond-drilling at the Harryhousen group, near Phœnix, until needed improvements can be made.

Mohave County.

W. H. Cushing, of the Stockton Hill Mining Co., has taken over the Moonbeam mine, near Kingman, owned by McLean, and the K.P. and P.K. mines, owned by L. Kimerly and J. C. Potts.——A mill is to be erected on the Cupel mine, near Kingman, and the ore is to be dressed for market.——The Cerbat Mountain Mining Co. is considering putting in a mill at the Vanderbilt mine, near Cerbat.——Owing to the volume of water at the Idaho mine, near Cerbat, sinking has been discontinued at the 125 level, and drifts will be run on the orebody.——W. G. Blakley and J. C. Goodwin intend to put a stamp-mill on the railroad near McConnico to test ores from various sections.——Sinking is to be resumed at the Enterprise mine, near Kingman, to the 500-ft. level.——The 10-stamp mill of the Vivian Mining Co., at Vivian, will be opened on March 11.——L. D. Godshall is installing an automatic sampler at the Needles smelter.

Pinal County.

The Big Lead Mining & Smelting Co. is to build a 100-ton concentrating plant at its mine, near Florence, under the supervision of F. A. Adams. The plant will be equipped with Hancock jigs.

Yavapai County.

Morris Crump is developing his properties with a small force and is getting out rich ore. This group is near the head of Lynx creek.——A. G. Curtis is working his properties and getting good results, and J. P. Score, who has been working on his mines for several years, has also struck good ore in a shaft that he is sinking on one of his claims.——The Metals Mining Co. is running a tunnel on the Eureka mine, and making a raise to connect with the shaft. A large body of ore was recently struck in this tunnel when it reached the vein.——A. H. Mitchell is developing his Independence and Poor Man mines and has a shaft down 100 ft. on the latter, from which he has run two drifts, in which he has opened up a vein two feet in thickness. On the Independence mine he has two shafts down 30 ft., on a ledge carrying good values in gold and silver. The mine is on what is known locally as the Mudhole vein.

The Copper Mountain Mining Co. has cut a station in the shaft of the mine, near Stoddard, and as soon as the hoist is ready will sink to 600 ft. and will open orebodies by drifts and raises.——M. J. Whelan, superintendent for the St. Anthony Mining Co., has men at work installing a hoisting plant and other machinery at the Mark Twain and Eighty-six mines, near McCabe, preparatory to beginning development.——P. McLeod has sunk a shaft on his group near Prescott.——The Metals Mining Co. is running a tunnel on the Eureka mine, near Prescott, and is raising to connect with the shaft.——The owners of the Binghampton mines, near Stoddard, will shortly duplicate the present hoisting plant on the mines.

Yuma County.

The Wendendale Gold Mining Co. is contemplating the erection of a sampling plant at Wendendale, near Planet.——The Harqua Hala mine, near Planet, is to be re-opened after an idleness of over 10 years.

CALIFORNIA.

Butte County.

O. B. Perry, of San Francisco, representing the Pacific Gold Dredging Co., is building a Bucyrus dredge on the Jacobs tract, near Oroville. The dredge will be equipped with 7-ft. buckets, and will be ready for operation next week.

Kern County.

H. H. Blood, who is putting in a 10-stamp mill in the Amalie district, above Caliente, states that the new mill will be completed in 30 days and will be ready for custom ore within 90 days. He has power sufficient to operate a 20-stamp mill, and 10 additional stamps will be put in, if conditions warrant it.

Mono County.

It is reported from Masonic that the Liberty-Pittsburg claims have been sold to a Denver company by Dorsey, Phillips & Bryan. Work will commence on the properties the coming month, when a contract will be let to run a tunnel to tap the ledges that have been opened by the lessees.

Nevada County.

It is reported that a 15-ft. ledge of high-grade ore has been struck on the 700-ft. level of the Murchie mine, near Nevada City.——The Sultana Mining Co. has finished its air-shaft. Work will soon be commenced on a large mill for this mine.——W. Howard and R. Kemp will resume operations on their property at French Corral, near Grass Valley. A tunnel will be run to the ledge at depth.——G. Shebley and J. Orzalli are developing a claim on the Orzalli ranch, at Chicago Park, and are down 90 ft.——A portion of the new mill for the New York-Grass Valley mine, near Grass Valley, has arrived. ——The shaft at the Prescott Hill mine has been pumped out and sinking commenced. No work has been done at the bottom of the shaft since 1867. The compressor at the mine supplies power to 16 machines and two hoists.

Placer County.

W. P. Hammon will operate two dredges on Bear river near Sheridan this season. Machinery for the dredges is arriving at Sheridan.

San Bernardino County.

J. Faris, of San Bernardino, reports having located a claim near Banning. No mines have thus far been developed in this vicinity.

A rich gold strike is reported made 18 miles west of the Colorado river, near Needles. Over 300 prospectors are on the ground, and people pouring in from all sections. Saturday morning County Recorder Johnson expressed 500 location blanks to the new camp. A prospector who filed a location states that the strike was made early in February, but had been kept quiet until last Wednesday.

Shasta County.

The Great Western smelter, at Ingot, has been closed on account of bad roads, which prevent coke being shipped to the mines from Bella Vista.——The owners of the Red Ledge mine, near Redding, are considering putting in a 5-stamp mill, concentrator and slimer.——Hill, Spencer & Laycock have sold a one-sixth interest in their quartz claim near Kennett to R. W. Evans of Kennett.

Charles Smith, a miner, fell 320 ft. down a shaft in the Afterthought mine, at Ingot, on the 11th inst., and was killed instantly. He was returning from the dump with an empty car, which he pushed so rapidly that it broke the wooden bar shutting off entrance to the shaft when a cage is not resting on the chairs. The cage was above, when the bar gave way and the car fell into the shaft, carrying Smith with it.

Siskiyou County.

The Bills-Reichman mine, on Indian creek, near Fort Jones, has been leased to Stearns & Sullivan.——An air compressor, a 50 h.p. gasoline engine and a car of gasoline are now on the road to the Blue Ledge mine, in this county, near Medford, Ore. Three tunnels are being driven on different levels and winzes are being sunk to connect the tunnels.

Trinity County.

H. Ehrmann and E. S. Kise report having struck a pocket in the White Cloud placer mine, near Lewiston. ——P. L. Young, of Orleans Bar, representing English parties, has a number of quartz mines on Eagle creek, near New River.

The Laymon boys, who own a placer claim on Kingsbury gulch, five miles from Hayfork, have struck a back channel which is 60 ft. wide, which they can trace 600 ft. up the gulch. The gravel averages 25c. per pan on the bedrock. They have been piping for a month and have picked up $75 in nuggets.

Tulare County.

E. L. Blossom, of San Francisco, has bonded the C. Brown property near Plano. He will begin work within 60 days.——The Powell copper mine, near Porterville, has passed into the control of H. J. Mueller and others and will begin development. Supplies are now being shipped to the mine.

COLORADO.

According to the reports furnished by the companies, the United States Zinc Co., whose plant is at Pueblo, purchased, in 1905, 28,494 tons of ore containing 9,556 tons of zinc, an average of 33.5%. The production of spelter for the year was 6,544 tons. The United States Smelting Co., with plant at Canon City, smelted 33.000 tons of ore, containing 7,500 tons of zinc—22.7%; 2,900 tons of lead, 8.8%; 600 tons of copper, 1.8%; 300,000 oz. of silver, nine ounces per ton, and 2,200 oz. of gold, 0.066 oz. per ton. Excepting 800 tons of ore from Arizona, all was obtained from Colorado. The products of this plant are zinc-lead pigment and copper matte. The averages computed do not show the grade of zinc ore smelted, inasmuch as some copper ore, free from zinc, is smelted along with the zinc ore.

Clear Creek County.

The Dives-Pelican mine, near Silver Plume, is to have

an aerial tram, which will avoid delays in the delivery of ore to the mill.

Gilpin County.

(Special Correspondence).—The Fifty Gold Mining Co. has recently been organized to operate the old Gregory and Bobtail property. The Cook shaft, down 1,300 ft. will be continued to the 1,700 ft. level. They will crosscut at the 1,300 ft. and 1,700 ft. levels to the Gregory vein and also drift to the Fiske and Bobtail veins. To accomplish this work it is estimated the company will spend $150,000 for new machinery. A. B. Thompson, General Manager.

Black Hawk, March 10.

Illinois and Iowa people are associated with Coloradoans in the development of claims on the dividing lines of Gilpin and Summit counties, west of Russell Gulch, of which L. D. Bloom is manager. The company is called the Bald Mountain Mining & Development Co. It is the intention to run a tunnel 3,000 ft. to develop the group, the tunnel being in 100 ft. Part of the group is patented. For present development the L. D. B. shaft has been unwatered and sinking operations are proceeding, this shaft being down 85 ft. The company intends to sink to 140 ft. and crosscut and drift. They are talking of the installation of machinery in the future.

Sinking is in progress at the Morris shaft of the Pearce Gold Mining Co., in the Russell and Lake districts, south of Central City. A depth of 300 ft. has been reached and the company intends to sink to 400 ft. Ore is reported in the shaft. Frank Hardy is superintendent, and H. G. Pearce, of Denver, manager.

The Jupiter-Belmont and St. Claire mines, in the Russell district, are being started up by the Jupiter Leasing & Mining Co., under the superintendency of J. C. Williams, of Russell Gulch. A new shaft building is being built. The machinery consists of a hoist and boiler. It is expected that the top improvements will be completed inside of the next week. The main shaft, down 500 ft., will be unwatered and re-timbered wherever necessary, after which an examination will be made of the property to determine upon future operations.

Hinsdale County.

Two cars of ore went from Lake City last week, one each shipped by the Planet Co. and the Emerald Isle leasers.——C. E. Peniston has given a bond and lease on the Independence lode to L. A. Vinton, Sherman Williams, Ed. Lampert and Coley Kirker, for $20,000. The Independence is patented and situated on Sheep mountain, and has produced a great deal of ore in times past.

Lake County.

The Cloud City Mining Co. has been in operation three years and as a result of work done is in shape to produce a regular output of manganiferous iron. The shaft is 630 ft. deep with a good pump at the bottom. An eight-inch air-pipe, to which a small steam jet gives suction, carries good air to the breast of the north drift, now out 600 ft. and under Fifth street. Since the Home Extension shaft and ground was added to the Cloud City holdings, a connecting drift of 1,125 ft. has been run between the two shafts. In the vicinity of that shaft an output of manganese began two months ago in the course of development of the old ore-shoot. As a result of this work there is in sight at three different points what appears to be a strong body of this ore.

Las Animas County.

To divert the water of Las Animas river, convey it through a tunnel seven miles in length, generate 30,000 h. p., and return the water to its natural channel, is the plan of a project to be undertaken by the Animas Power & Water Co. Henry Jameson, of Indianapolis, is president and states that the work will cost $1,000,000. They own the Rockwood dam, between Durango and Silverton, which conserves water that generates 6,000 h.p. The dam is 55 ft. in height and will be raised to 110 feet.

Park County.

(Special Correspondence).—The Snow Storm Hydraulic Co. of this place has placed an order for 3,300 ft. of 28, 29, and 30-inch hydraulic pipe, for use on the Alma siphon line. This pipe will be put in commission as soon as the weather will permit of the work being done.

Fairplay, March 10.

Summit County.

(Special Correspondence).—Indications are for an early start in dredging and placer operations. The management of the Reliance Dredge Co., in French gulch, will put on men next week to overhaul the dredge and get it in shape to start digging as soon as the weather permits.——The Abundance Co. is installing a large boiler on its property at Yuba Dam flats. The company intend to sink to solid formation by shaft and a churn drill, when a diamond drill will be employed. The main tunnel being run by the same company into Mineral Hill from French gulch is in 400 ft. Eight hundred feet will bring the adit to the Abundance. It will also develop the Mono group, which adjoins the Abundance and Oro.——At Kokomo P. W. Breene has disposed of his holdings for $500,000. The property has been purchased for a Milwaukee syndicate. They intend to erect a large mill.——Another important deal has been closed in Breckenridge whereby the Wire Patch has been acquired by Mark G. Evans of Denver for his associates. This property is situated on Farncomb hill. The whole of this section of Farncomb hill would, it is thought, pay to put through a mill of large capacity.——Foote & Hight are working their lease on the Bullion King of Gibson hill and are making regular shipments of high-grade zinc ore.——The Atlantic mine, on North Star mountain, is yielding 15 tons of gold ore daily. When more teams are available, the operators will increase the output to 25 tons a day.——The main ledge in the Country Boy is improving and promises to become one of the chief zinc producers in the district. The drift on this ledge is in 350 ft. and has passed the area where the zinc was worked out above. There is now showing a ledge 4 ft. wide.——The Sallie Barber mine, on the north slope of Mt. Baldy, is being worked by Leadville and Canon City parties. The vein has opened up in the shaft to a width of 3 ft. Sinking has been stopped and drifting is in progress. It is intended to start a new main vertical shaft. Two cars of high-grade zinc ore have been shipped to Canon City.

George Horne, working the Leona and Edna properties, brought in samples from a 3-ft. vein which assayed up to 10 oz. gold per ton, besides good values in silver.——A strike has been made on the Silver King property by Widmar & Dean, situated on the crown of Nigger hill, at the foot of Bald Mt. In drifting east from the Dean shaft away from the main ledge, a branch vein was encountered, carrying lead sulphide in bunches. The ore is high grade and carries gold and silver.——The Jessie mine is opening up well in the Glenwood level workings. Manager Morgan is having the 40-stamp mill overhauled.——The Wellington mine is shipping regularly. The Gold Dust is getting ready another shipment of gold ore. The Morning Star mine is running steadily and when spring opens will make shipments regularly.——The Old Union Mining & Milling Co. will get the mine in shape for making a continuous run.——J. E. Parker, of Memphis, Tenn., president and manager of the Mary Verna and North American mining companies at Frisco, arrived here on Friday last with 14 Southern capitalists who are interested in the Ten Mile mines.——The Minnie mine, in Mineral Hill, is producing shipping ore and piling up milling ore for concentrating in the spring.

Breckenridge, March 10.

IDAHO.

Kootenai County.

The Gold Ridge Mining Co., owning six quartz claims on the St. Joe river, near Cœur d'Alene, cut the main ledge in the bottom of the 90-ft. shaft last week. A tunnel will be run for drainage.——It is reported that a 10-in. vein of galena has been struck at 100 ft. in the tunnel at the Rose of Killarney mine near Priest river.——The Green Mountain Mining & Milling Co. will put in a 5-stamp mill on its property near Tyson, and a larger mill will be installed later.

Idaho County.

The Idaho Consolidated Copper Co. will erect a reduction works with a capacity of 100 tons on its property near Grangeville, and an electric plant will be installed. Seven hundred feet of tunnel has been run.——A stamp-mill will be built on the Dice property near Grangeville.——The Copper Queen Co. will instal a smelter on its property near the Evergreen mine at Clearwater, where a ledge 12 ft. wide has been uncovered.——The Big Baldy Mining & Milling Co. will increase the force at its mine near Hump and more machinery will be added.

A. W. Boyd has put in the cyanide plant for the Seattle & Idaho Mining & Milling Co., at the Comstock mill at Dixie, and the mill is in successful operation. The plant has a capacity of 30 tons daily. The ore is classified and the slimes run off, as they are comparatively valueless. The ore is crushed by two 2-stamp batteries, crushing to four-mesh screen. The stamps are only run one shift and crush 30 tons. The ore is mined by the glory hole system, one man breaking the rock and tramming it to the crusher. At present they are leaching the pulp for 24 hours, and save a fair percentage, which, with the extra amount of pulp handled, gives satisfactory returns. The ore is being mined and milled for 90 cents a ton, and when they can use water for power, it will be materially lessened.

Nez Perces County.

Difficulty has been experienced at Pierce this spring in getting supplies and machinery from the railroad, owing to the bad roads. The Idaho Co., which is installing a dredge, has kept teams constantly on the road between here and Greer, and almost all its machinery and lumber have been delivered. All the available men here and a number from outside points have been employed by this company, and work on the dredge is progressing.——J. W. Nelson, president of the Ozark Mining & Milling Co., and J. P. Rossman of St. Paul recently inspected the work at the Ozark. Since this company took the mine last fall 1,000 ft. of tunnel work has been done.——Frank Cole, the patriarch of the camp, has been identified with the Pierce City district since 1861, and was sheriff of Shoshone county in the early days.

Shoshone County.

L. W. Stedman will put in a sawmill and build a 2,700-ft. flume on his property on Pritchard creek, near Murray. The creek will furnish 100 h. p. in the lowest stage of water, and will operate a 10-drill compressor. Power will be furnished the Paragon, Blackhorse and Chicago-London mines.——A new Huntington mill has been installed at the Hecla mine, near Gem. S. Logan has shipped a car of ore recovered from mill tailings in the creek by means of Joplin jigs.——Sinking has begun on the Rex mine, near Wallace. A shaft will be sunk on the ore-shoot to 100 ft. The mill will start March 15, after having been closed down on account of water shortage.——A compressor will be installed at the Columbus group, near Murray.——Five stamps are dropping at the Mother Lode, near Murray. A concentrator leased from the Golden Chest has been installed, and Superintendent Thyne is making preparations to start up the Golden Chest 20-stamp mill.——The Golden Reward mill, near Murray, is dropping stamps during the day.

The bailing of the shaft of the Helena & Frisco mine is proceeding. The workings are unwatered to 600 ft., leaving 800 ft. to be unwatered. The quantity of water hoisted so far is 43,000,000 gal. To complete the unwatering of the mine and instal the pumps for continuous operation will require two months more, but Manager Ehrenberg expects to begin mining about the end of April.

The development of the recently discovered ore-shoot in the Tamarack & Chesapeak mine continues. The drift has been run with a width of 14 ft. for two weeks. This drift is on the hanging-wall side of the vein, and has shown in the face from 6 to 9 ft. of clean shipping ore, which was sacked as it was broken down. For the greater part of the time the rest of the face has been concentrating ore of such grade that it could be sorted by hand three tons into one. Last week a second streak of clean shipping ore appeared on the foot-wall side of the drift. A drift has been started on this streak and now shows three feet of clean ore. The ground between the two drifts is slightly mineralized and is left for the present.

A strike was recently made near the head of Placer creek, six miles from Wallace. It is a gold strike—something new in the Cœur d'Alene of late years. The discovery was made on the Vienna and International claims, owned by N. Miller, J. and A. Livingstone and J. H. Graham. They are old locations, having been staked in 1891 and held by the present owners ever since. They are situated two miles from the wagon-road up Placer creek, with which they are connected by trail. The owners of the property have been driving a crosscut tunnel to develop a ledge. When in 100 ft., they cut an 18-in. ledge of quartz and iron and passed it as not worth anything. As things were far from lively on Placer creek, little was done outside of annual assessment work for the past few years and the rock was so hard in the face of the tunnel that the owners looked for an easier place. Alongside the vein of quartz and iron the rock was broken up and easy to work, so it was concluded to represent for the year by driving alongside the ledge. Two weeks ago they broke into the ledge of iron to see what it looked like, with the result that a solid body of white quartz and iron was crosscut for a width of 10 ft. A sample went $60 per ton in gold. A number of other samples ran from $14 to $45. Samples of the clean white quartz assayed ran $4 per ton. The owners have now concluded to open up the ledge with a view to shipping, and are confident they have a bonanza.

MONTANA.

Granite County.

The district about the Garnet group has been active, the few months past, particularly at the Clipper group, and others near them on Mineral hill, near Pony. The Garnet mine is increasing shipments to the Helena smelter. On the Diamond G claim is a 50-ft. shaft, toward which Daniel Brand, who has the mine under bond, has been running a tunnel to tap the ore at a depth of 130 ft. The shaft is all in ore, which assays $27 in gold and some lead. The tunnel is in about 120 ft. The Eighteen-Ninety lode was recently bonded to Kern Adams, of Butte. Float on this claim assays from $3 to $100 per ton. Mr. Adams is driving a tunnel into the hill, in which he has struck, sooner than he expected, a four-foot vein of good ore. Near the Diamond G and above the Eighteen-Ninety the Mogul has a 400-ft. fraction between the two latter. The Mogul is owned by Charles Young, W. R. MacFadden and John Milligan, and the fraction by Charles Young and A. J. McCormick. The Mogul has a 20-ft. shaft, with 18 in. of ore assaying $26 in gold and 16% copper. A crosscut tunnel has been run into the hill 130 ft., with 80 ft. more to run to tap the lode. The fraction has an 80-ft incline, with a drift at the bottom. Some of the ore assays $38 per ton. Several more prospects on the same hill are opening up favorably.

A rich gold strike at Six-Mile house was reported last week, which has resulted in much activity there. Adjoining claims have been located for several miles on both sides of the canyon and prospectors are digging holes and making the necessary showing for locations. Several of the prospects are reported to be encouraging.——Mr. Bennett and sons are driving a tunnel to tap their lead. They are also doing work on other leads parallel with the original discovery, and in one copper ore is found.

P. Loughrin, who owns a ranch one mile north of Bennett's, has struck a 14-ft. vein of ore. His strike is not new. Mr. Loughrin had been at work on his claims for several years, having a good showing in a number of places. He has been running a tunnel to cut his lead. The rich strike at Bennett's caused Mr. Loughrin to renew his efforts and a few days ago a strong vein of ore was cut.——Other prospects are showing up rich copper ore in several places within a mile or two of Flint station. The claims owned by Bhen, Blackburn & McRae near Flint, in addition to the copper prospect, have an eight-foot vein of lead-silver ore.

Jefferson County.

Near Clancy, and situated three miles east of the Liverpool mine, are the Raymond and Superintendent mines of the Raymond Silver Mining Co. C. F. Murphy, of Great Falls, is president of the company: O. D. Thompson, of Butte, vice-president; Jesse E. Teague, of Clancy, secretary. A tunnel has been driven on the main lead of the Raymond 260 ft. and a shaft sunk 49 ft. In driving the tunnel 11 tons of ore were taken out and shipped to East Helena. The first shipment ran $55 per ton and the second $62.

Missoula County.

Drifting will be started at the Tarbox mine near Saltese as soon as crosscutting of the ore is completed. The winze will be sunk to the 600 level and another crosscut made at that level.

Recently the Ann Arbor Mining Co. transferred to R. deB. Smith and associates a large tract of placer ground on Dry Creek, near Iron Mountain, for $125,000, the first payment being made the latter part of February. This ground will be worked on a large scale. Mr. Smith consummated another deal by which he acquires another 140-acre tract of placer ground on Dry Creek, near Missoula, for $75,000. This ground is in the same gulch as the Ann Arbor Co., but is higher up and has never been opened up, although it prospects well. The sale carries with it a water right of 2,000 inches. It is not likely that dredges will be installed, as the ground is in an ideal locality for hydraulicking, with an abundance of water.

Manager Daxon, of the Tarbox mine near Saltese, reports the showing in the crosscut on the 500 level as being good. The crosscut has cut the ledge for 30 ft. without reaching the hanging wall. The first 12 ft. of the ledge is concentrating ore and the rest is white quartz impregnated with galena which occasionally occurs in large masses. He has decided to resume sinking the winze. When the 600-ft. level is reached another crosscut will be run to the ledge.

Silver Bow County.

(Special Correspondence).—The Anaconda has for some time been drifting on the vein which was opened several months ago at a depth of 2,200 ft., and the richness found at the crosscut continues. The same vein has been encountered at the depth of 2,400 feet.

The report is circulated in Butte that none, or at least few, of the big producing mines of the United Copper Co. are included in the Red Metal or Butte Coalition companies, supposed to have been formed to take over the Heinze properties. It is stated that the chief assets of the Coalition are some of the smaller mines of United Copper and the Alice group. If that is true it is probable that, in the settlement with Heinze, some of the best ground in dispute was turned over to the Amalgamated Company.

The Furnace Creek Copper Mining Co., organized by Patrick Clark, of Spokane, and others, has been floated, and 125,000 shares of stock allotted to Butte were subscribed in less than hour. The property of the company is near Death Valley, Cal., where prospecting has been carried on for some time, it is said, with encouraging results. Mr. Clark has also secured a number of properties in the undeveloped portion of the East Butte district, and will organize the Bullwhacker Mining Co. to take them over.

A $35,000 gold bar, the product of a 40 days' run of the mill at the Cable mine, 50 miles west of Butte, was shipped to this city a few days ago.

The Butte Copper Exploration Co. has pumped the water from the 400-ft. shaft on the Six O'clock mine and in a few days will have the old shaft ready to resume sinking. The property of the company lies just north of and adjoins the Pittsburg & Montana mines.

The Butte & Bacorn Co. has been organized to develop a number of claims still north of the Butte Exploration Co. This will be a close corporation and the public will not be asked to take a chance. Ten capitalists, mostly from Pittsburg, have put up $45,000 each as a working capital, with which the ground will be explored.

The General Development Co., backed by the Lewisohns of New York, is making good progress in re-opening the Altoona group, east of the city, consisting of the Altoona, Amazon, Maccaroni, Montgomery, and a portion of the Coleen Bawn quartz claims, and the mineral rights to a portion of a placer claim. J. Parke Channing spent several weeks in Butte examining the properties. Before leaving, Mr. Channing started the work of cleaning out the old shafts and workings, and when that is completed sinking and further exploration will be done.

Butte, March 11.

NEW MEXICO.

Luna County.

H. R. Fry has made a find near the old Victoria mines, south of Gage. Recently he opened negotiations with the Hearst-Tevis estate regarding the dumps of the Victoria mines and visited the properties. The Victoria mines are in a small hill, three miles from Gage station. Large pockets have been found in the mines containing ore that ran high in lead and silver. It was worked many years ago. Some years ago Michael Burke, of Deming, secured a lease on the mines and followed a streak of ore which led to a pocket, from which it is reported he cleaned up $75,000. While Mr. Fry was at the mine, he noticed a couple of more small hills, and concluded to look them over, and found a prospect hole on one. Ore from the dump assayed 25% lead and 40 oz. silver. He located the long-abandoned prospect. The deepest opening on these claims was not over 15 ft. The place is near where H. F. Brinkman discovered the abandoned wolframite property.

Otero County.

An 85-h.p. boiler and an air-compressor with a capacity of eight drills and two hoists, one 8 by 10 on the surface and one 4 by 6 underground, have been installed at the Nannie Baird mine, near Jarilla. Levels will be cut and driven every 75 ft. in the mines. The vertical shaft is to be sunk deeper and a new three-compartment working shaft sunk where a diamond drill-hole was put down several years ago. A vertical shaft is being sunk in ore at the mouth of the old incline shaft. This will be 4½ by 8 ft. in the clear. —— Two 85-h.p. boilers are being installed at the old power house at the Lucky mine, near Jarilla; also a 16-drill compressor. At the collar of the shaft an 8 by 10-in. hoisting engine is to be operated by compressed air. The entire workings are to be tracked, and on the third level the formation is to be crosscut to the first, second and third contacts. An aerial tramway will be run from the Lucky to the Iron Mask, at which three machines will be placed. Bins will be erected at the mines with a capacity of 500 tons.

The Electric Mining and Milling Co. has been organized to work the placer grounds at Jarilla. T. R. Hall is president and G. E. Moffett, of Jarilla, secretary and manager. They expect to have their plant in operation by July and think they have enough gravel to run 25 years. Crystals of zircon have also been found in the placer ground. This has heretofore been a dry-washer camp and by this process gold has been produced every year; but, with the advent of water through the pipeline now being laid, new life will be given to placer mining. The reservoir will hold 25,000,000 gal. and will supply water for the mills and smelters handling the ore from the lode claims and also abundance for placer ground.

Sierra County.

The mill at the Enterprise mine, near Mogollon, is to begin operations in April.——The Black Peak mill, near Hillsboro, is running steadily on ore from the Wicks mine. M. F. Burks is in charge of the mill.——The contract for building the 400-ton smelter at Jarilla for the Southwest Mining and Smelting Co. has been let. The smelter will cost $300,000.——Surveyors have been making a survey of a tramway from Pyramid to Lordsburg. The survey shows that it would be an economical way of getting ores of that district to the railroad.

A strike of gold and silver ore was recently made in the Good Hope-Bonanza mine in Las Animas mining district at the 150-ft. level. There is a pay-streak of two feet running 3 oz. gold and 200 oz. silver.——This district has had a number of new strikes and many of the old mines are being worked. New mills are being constructed and the old ones remodeled and put in order.

NEVADA.

Esmeralda County.

(Special Correspondence.) — The new Kinkead mill completed about March 1 is running on ore from the Kendall mine, on Columbia mountain. In this mill are three of these mills with room for two more. There are also three 6-ft. vanners, and a concentrate is being saved worth $120 per ton. The ore is amalgamated on outside plates. A cyanide plant is contemplated by the Kinkead Mill & Mining Co., owning the plant. J. H. Kinkead is superintendent. On the mines about Goldfield a large amount of work is in progress, principally by lessees, who ship the high-grade ore and send the lower grade to the custom mills. A great many of the floating population at Goldfield have gone to Manhattan, and other newer camps in this part of Nevada. A good body of ore is reported on the 300 level of the Sandstorm mine, which will have a tendency to stimulate deeper mining in the camp. As water is scarce in the district, all the water used in milling at the Kinkead mill is settled in pointed boxes and pumped back and re-used, with a loss of 25 to 50%, depending on atmospheric conditions. The water used at this mill is pumped from the Highland mine at Diamondfield, four miles distant, and costs $1.50 per 1,000 gal. This mine makes about 120,000 gal. per day, which affords the owners a substantial revenue.

Goldfield, March 12.

Manager Bertschy, of the Aurora mine at Aurora, states that the tunnel will be continued 120 ft. to the foot-wall.——Peters and Pettitt and others, who recently secured block 7 of the Columbia Mountain Mining Co., at Columbia, are preparing to instal a whim and continue sinking.——An important strike is reported on the Combination Co.'s ground at Goldfield, where a 7-ft. body of ore has been disclosed. A force has been put to work drilling into the body to find the foot-wall.

The Nevada Iron Cap Mining Co. is preparing to put down a shaft from the end of the present 95-ft. tunnel to a depth of 500 ft. on the Iron Cap mine in the Palmetto district, near Goldfield. —— Arrangements are being made to resume operations on the Gold Quartz group in the Red Mountain section, three miles east of Diamondfield.——The Diamond Triangle Co. will crosscut at the 75-ft. point in the shaft on the Lulu Fraction mine, near Diamondfield.——The new 25-h. p. gasoline hoist on the Booth claim, near Goldfield, began operations last week. The shaft will be sunk 200 ft. —— Sinking has been resumed on the Peer mine, near Goldfield. —— F. N. Fletcher and others, of Goldfield, have taken a lease on the old Bullion mine at Montezuma, and have put men at work to complete the tunnel. —— A hoist and other mining equipment has been ordered by the Chipmunk Gold Mining Co. for the Chipmunk claims at Manhattan.

Thirteen sacks of ore mined on the 50-ft. level of the Sandstorm, reported averaging $6 per pound, and 13 sacks of ore, averaging between 2 and $3 per pound, were recently sent to Selby. The smelter company reported the following result: Thirteen sacks of ore, averaging 560 oz., value $11,200 per ton; thirteen sacks of ore, averaging 230 oz., value $4,600 per ton. The rich ore was mined in the Sandstorm during the second week in January, and was of so great a value that the sacks containing the earth were stored in the vaults of the John S. Cook bank until they could be prepared for shipment by express.

Marietta, which was a prosperous mining camp but abandoned since 1880, is likely to come into prominence again, a Boston syndicate having secured an option on a majority of locations in the district.

Eureka County.

D. C. Turner and J. Campbell, of Reno, are at Palisade, arranging to send out the first shipment of bullion from the new 50-ton smelter of the Mineral Mining & Smelting Co.

The Richmond-Eureka Co. now has 90 men employed, not including officials.——The cribbing of the Eureka Consolidated shaft has been completed to the 900 level, and as soon as the guides are in place miners will go to work in the levels.——The Richmond-Eureka Co. has increased its outside force of graders and builders. The company is building an office at New Town and grading has been started for a warehouse.

Humboldt County.

Since installing the new hoist and pump at the Bonanza King, near Lovelocks, Superintendent Cornes has been drifting on the 225-ft. level to catch the ore-shoot. There was a fault in this shoot and after it had been mined to 200 ft. deep, 300 ft. long and 4 to 6 ft. wide, this chimney gave out. After drifting 50 ft. from the bottom of the shaft the men are now coming into the same ore-shoot, which had yielded so richly at the top. Pannings show that it carries good values.

Castle & Lynch have returned from California and are going to put in a five-stamp mill on their property at the head of American canyon. They have purchased the mill at the mouth of Limerick canyon and will move it to American canyon. They also have a gasoline engine and will start in with this outfit to work ores from their claims situated at the top of the divide between American canyon and Dry gulch.

Lincoln County.

The Quartette mine is a mile from the town of Searchlight. The Quartette mills that are being dismantled are 18 miles from Searchlight. The mills of the Quartette Co. are to be reconstructed at their mine.

The Ross group, near Uvada, Utah, is being opened by a tunnel which is expected to cut important ore-bodies.——The Uvada Gold Mining Co. has begun tunneling to crosscut three claims in the company's ground, which joins the Snowflake and Jenny properties.——The Jenny Gold Mining Co. is sinking a shaft on its No. 7 claim, near Uvada, Utah. A new ledge is being opened. ——Work is being prosecuted in the Indiana tunnel of the Deer Lodge Mining & Milling Co. at Deer Lodge. The Iras mine at Deer Lodge is to be opened by Moody & Dameron, who are now putting the Homestake mill at Deer Lodge in shape to handle the output of the Iras. ——C. A. Hopkins, of Searchlight, states that 20 stamps will be added to the Quartette mill, near Searchlight, which has 20 stamps in operation.——J. Brockman and Mr. Portalis, of the Good Hope and Duplex mines, near Searchlight, state that both will be opened to a depth of 1,000 ft. before a larger mill will be put in.——Contracts for sinking have been let in Searchlight district as follows: Searchlight Bonanza, 240 ft.; Searchlight Copper-Gold, 150 ft.; Combination, 240 ft.; Mountain, 125 ft.; Goldyke Mining & Milling Co., 225 ft.——The Searchlight Mining & Milling Co. reports having opened a large body of ore on the 250-ft. level at its mine, near Searchlight.——The Searchlight Treasure Gold Mining Co. reports finding a large vein of free-milling ore while tracing a lead on the Gavilan claim at Searchlight. This find is in the center of the town of Searchlight——W. M. Brown, manager of the Long Beach Mining & Milling Co., has let a contract for the first 300 ft. of sinking on the Alice V. lode, near Searchlight.——A flow of 40,000 gal. of water is reported at the 240-ft. level in the Santa Fe mine, near Searchlight.

Baxter Springs is promised increased activity through the letting of 10 leases by the Baxter Springs Mining Co. on their claims. Leases will be 100 by 750 ft., 10 months' time, 20% royalty, no bonus, 25 shifts the first month and 52 shifts per month thereafter. There is plenty of wood, also water, on the ground, and, with such favorable terms and conditions, it is expected the lessees will do well. Sixteen new tents were erected at Baxter Springs in three days, making the camp one of 400 people.

J. W. McNeil has given an option on his mining interests in the Baxter Springs district. Mr. Turner, of Baxter Springs, intends starting a stage line between Tonopah and Baxter, making three round trips weekly; fare, $6 each way. He reports a strike on the Davenport property, four inches of black quartz on the hanging wall of the ledge being impregnated with free gold.

Nye County.

(Special Correspondence.) — A few lines from this locality may be of interest. Being a miner, I struck this camp about a year since, and after looking around a short time concluded it was good enough for me, so here I am yet and not sorry for stopping, although I haven't sold a single prospect, since making my first location. I brought lumber here from Manvel on freight wagons, costing here $115 per thousand ft., over 110 miles; bought grub here, and glad to get it: Flour $6, onions 14c. per lb., spuds $7.50 per sack; bacon 23c., hams, 25c., other things in proportion, but it shows to anyone the reasons why this locality has not advanced faster than some others—namely, distance from any railroad and cost of living. But now times are changing, and why? The mines are here, and the Tonopah & Tidewater Railroad is running regular to the Indian creek, where they are putting in a station and laying steel beyond at the rate of one mile per day, to the next station, 30 miles north of Indian creek, which will soon be reached. Distant from Johnnie seven miles, two grading camps are already across the Spring Mountain range, and are going for Bullfrog. Ash Meadows and Miller's Wells will soon have two streaks of steel and the right of way across its dreary sands, and the days of famishing freight teams and stage horses will be able to step aside and rest, while the iron horse goes jingling by—'hurrah for the iron horse!' he brings us in touch with the outside world; brings us lumber, machinery, visitors and investors, and gives us also a chance to ship out lead-silver ore, and hematite, of which we have some grand properties, and all hands here who own this character of mines are exerting themselves to see who can get the first carload out toward Salt Lake, or the Caliente smelters. The Johnnie mines, now down 700 ft., and belonging to Los Angeles people, require very slight mention. It is a *mine*—pronounced so by some of the best experts west of the Rockies. For instance, on the 500 level, with a 5-ft. vein, assaying $40 gold; on the 600 level, the vein 25 ft., assays from $18 to $45, while on the 700 level they are crosscutting for the ore, proving, as the company has already, that this 200-ft. ore-shoot extends up to grass roots.

A mining man from Utah has just found a large body of moiybdenite, four miles north of Johnnie, and put a force to work developing, and for a wonder it is inside of three miles of the new railroad, now building.

L. L. Patrick purchased a lead-silver property making a substantial cash payment, and has had men working constantly since and their 'super' tells me they are O. K. and wants more. I learn tonight of a great strike of silver north of Sterling, perhaps 20 miles north of this place—names of lucky discoverers not known here. The store in this place has recently changed hands and the purchaser has replenished his stock of general merchandise. Two shafts 50 ft. deep on the Battery ledge 6 ft. wide in bottom show free gold and high values. The Red mine group contains much shipping ore; main shaft down 40 feet, showing a vein increasing in width and value of ore increasing. A tunnel recently started to tap the ledge at depth shows fine ore in face, while from another group, the Rainbow No. 3, assays average $24 gold; these are all new finds, with the exception of the Johnnie Consolidated Co. Latest assays from Beryl group show 50 oz. silver, $12.50 gold and 20% lead. Shaft on a quartzite extension is 40 ft. deep and crosscut run 38 feet in ore which assays average $12.20. Gould & Place (new arrivals) have started a shaft on their lead and silver locations and are piling ore on the dump awaiting cars to commence shipping, and they haven't been on their locations to exceed three weeks. A British Columbia mining man, Rathburn, has purchased some lead and silver claims on Mineral flat and has men at work developing. There are others in this locality owning extensive lead-silver properties, all showing paying ores—as soon as we can get railroad transportation. West & Boller, Miller & Lampfrey, Lake, Smith, Body and Beauregard, all have properties of which they may well be proud, for they have staid with them, feeling that they could ill afford to let go, provided a railroad should ever come this way, and soon their hopes are to be realized, as the Clark road is practically here, and the Borax road, from Ludlow, has finished 40 miles of grade

and has 22 miles of track laid and still coming with steel at the rate of a mile per day, and will pass within 12 miles of this place on the west. A batch of Salt Lake men with a grand, good prospecting outfit, just arrived to look over this locality, intent on investing in something, no matter how extensive. They are examining the Clanahan mine which shows a ledge at 100 ft. in their tunnel assaying $104 gold. They have discovered an immense body of copper ore within a few miles of here, as they were coming in from Los Vegas.

Johnnie, March 10.

A contract for a 50-ft. shaft has been let on the Bullfrog-Keystone mine, four miles south of Beatty——The Gibraltar Mines Syndicate, of Salt Lake City, Utah, reports that it will equip the Gibraltar mines, near Bullfrog, with machinery and will sink a working shaft to a depth of 400 ft.——S. Newhouse, of Salt Lake City, has bought a controlling interest in the Montgomery Mountain Mining Co., owning claims in the vicinity of Bullfrog. He announces that a compressor, assay office, blacksmith shop and other buildings will be placed on the property.

It is reported that the Pinenut mine, at Manhattan, has been sold for $175,000 to C. D. Parker and F. W. Benedict, of San Francisco.

T. L. Oddie, representing the Eclipse, J. H. Carstairs of the Denver, and Sherwood Aldrich, representing the Tramps, are reported to have consolidated these Bullfrog properties. The new company is known as the Tramps Consolidated Mining Company.

The ore shipments via the Tonopah Railroad for the week ending March 9 were as follows: Tonopah Mining Co., 1,790 tons; Montana, 125 tons; Tonopah Extension, 695 tons; Belmont, 198 tons; Midway, 90 tons; West End, 43 tons; Jim Butler, 50 tons; Briggs & Evans, 34 tons; Nevada Alpine, 30 tons.

The Las Vegas and Tonopah railroad, under construction by W. A. Clark and J. R. Clark, is now in operation as far as Indian Springs, 44 miles from Las Vegas. A large amount of freight and passenger business for the Nevada goldfields is being handled. It is said that the new line will be completed to Bullfrog, 70 miles from Indian Springs, by May 1st.

Storey County.

Work has been resumed on the 425 level of the Gould & Curry and the north drift from the main west drift is being advanced in low-grade quartz.——Surface tunnel No. 1 on the eastern edge of the Dean ledge, owned by the Occidental Consolidated Mining Co., on the Brunswick lode, near Virginia City, is in 35 ft. in porphyry.——The West Justice tunnel of the Justice Co. is cutting low-grade quartz.——The Challenge-Confidence-Imperial main north drift from the Yellow Jacket shaft on the 900 level is in 709 ft. from the station. The face is in low-grade quartz.——On the 1,400 level of the Belcher mine the joint Belcher-Crown Point north drift from the east crosscut from the Belcher incline has been advanced 12 ft. through an old stope, making its total length 172 ft.——The joint Overman and Seg. Belcher south drift on the 1,400 level has been advanced six feet, making its total length 42 ft. in Seg. Belcher ground; face in hard, low-grade quartz.——Mexican reports having had $8,804.77 on hand March 1, 1906. Utah had $80.15 on hand and owed the bank $3,000. The latter company is collecting an assessment.——The water in the C. & C. shaft was 106 ft. below the 2,350-ft. level station on the morning of the 13th inst.

Washoe County.

The Rocky Hill Co. has commenced a tunnel to cut the orebody at the Rocky Hill mine, near Washoe City, at a depth of 500 ft.——W. L. Stevenson has bought a 25-stamp mill and a cyanide plant for the Green Hill Mining Co.'s proposed plant at Wadsworth.——C. W. Clapp, general manager of the Nevada Commonwealth Mining Co., is arranging for a reduction plant.

OREGON.

Baker County.

The sinking plant and compressors have been placed at the Dixie Meadows mine, near Prairie City, and the development of a 40-ft. ledge to the depth of 300 ft. will be begun.——E. T. Forrester has purchased the Ophir claim, near Prairie City, formerly owned by J. Forrester and G. Riley.

This week's production at the smelter totaled six cars of high-grade matte, the Idaho ores having been received despite delays incident to the breaking up of roads. The warm weather is playing havoc with the roadways and they are afraid that shipments will be slow for the next few weeks. They have started hauling halfway on sleds and established a midway station, from which the ores will be hauled in wagons to the railway station as soon as there are bottoms to the roads. Local shipments have continued, the regulars sending in quantities of ores and concentrates. The Copperopolis sent a car of concentrates. Gold Bug managed to get in eight tons of its high-grade stuff but it also must await better roads before resuming shipments.

Coos County.

The placer properties owned by the Commander Mining Co. are now equipped and two giants were operated last week.

Jackson County.

The Siskiyou Copper Co. has begun driving a 25-ft. tunnel at its mine in the Blue Ledge district, near Ashland.——Superintendent J. D. Heard has been working two giants at the Sterling mine, near Ashland.——A new compressor has been set up at the Blue Ledge mine at Joe Bar, near Ashland. Four winzes are being sunk.——T. W. Hill and others have purchased 40 acres of mining ground adjoining the Shorty-Hope mine, near Ashland. Mr. Hill is opening up other orebodies in that vicinity, preparatory to the installation of a reduction plant.——L. B. Chase will resume development at the Palmer mine.——It is reported that a cyanide plant will be installed on the Shorty-Hope mine, 3 miles west of Ashland.——A reduction plant is to be installed on the Wild Goose mines, five miles west of Ashland.——The Cyanide Gold Mining Co. is having plans drawn for a reduction plant to be installed on its property, near Ashland.——An air compressor has been installed at the Bill Nye mine, near Medford.——E. C. Faucett and associates are preparing to open up the Wright-Eckelson claims on Elliott creek, near Medford. They will put in a complete hydraulic plant, including giants and other machinery.

Linn County.

The Cinderella Mining Co. will erect a mill near Albany in the spring.

Malheur County.

C. N. Matthews and M. F. Hull have opened the Evening Star mine in the Sucker creek district near Grants Pass.

Union County.

The Co-operative mine near North Powder has installed a new hoist and has ordered machinery to cost about $7,500.

SOUTH DAKOTA.

Lawrence County.

The Gilt Edge-Maid property is at Turner. It is a low-grade proposition that requires large milling facilities and careful management to produce profits. The orebody is exposed 300 ft. long, and 75 to 85 ft. wide. Its total length is not known. Six hundred feet northwest of the present workings the ore has been found, and it may be continuous. On the lowest level of the mine are six chutes through which the ore is drawn that is broken in the open cuts. Several thousand tons of ore have been broken and can be drawn as required. The body is nearly vertical. The mill tunnel is 100 ft. below the top of the open cut, and the lower level 100 ft. below the mill tunnel level. From the open cut the ore goes partially to the chutes on the lower level. From the main tunnel level the ore is trammed to the mill, direct. From the lower level it is hoisted to the main tunnel and trammed to the mill. The open cut is 300 ft. in length, in the present workings, and 85 ft. wide. In mining raises are made from the lower level, breaking into the bottom of the cut. These raises are timbered and equipped with chutes. The ore broken in the cut passes by gravity through the chutes and is drawn into cars and conveyed to the mill. On the edge of the cut a hole usually 10 ft. deep is drilled. It is chambered by firing two or three light blasts of dynamite, then a big charge of black powder is poured in. This is fired, and the result is the breaking of a large quantity of ore. Boulders too large to handle are broken up with dynamite and hammers. The ore is conservatively estimated at $3 to $4 a ton. Occasionally bunches are found that assay above these figures, but they are not reckoned in the general average. At some points in the mine good-sized bodies of $10 and $12 ore are exposed. The Gilt Edge-Maid mill is operated by electric power. A number of small motors are used, so that each unit of the plant may be operated separately.

UTAH.

Grand County.

E. T. Wolverton has commenced the delivery of 5,000 tons of manganese ore for the Colorado Fuel & Iron Co. from their mines south of Little Grande.

Juab County.

(Special Correspondence).—A notable revival of interest in the Tintic district is marked by the recent increase in the number of operating mines. The advance in the price of silver has restored confidence in this once famous district, particularly near Eureka. From here the Centennial-Eureka mine, of the United States Mining Co., is shipping silver-lead ore weekly, and is now finding copper with increase in depth. It is an interesting fact that, contrary to the predictions of the geologists of the Survey, the best stopes are being opened on the cross-fractures and not on the main north and south fissures. This is also true of a number of other mines in the district. The greatest depth has been attained in the Gemini mine, of which Jackson McChrystal is superintendent. The main 1,600-ft. shaft, while not the deepest in the camp, has reached the lowest orebodies, as its collar is so low. While sinking a winze to the 1,700-ft. level water was struck at a depth of 1,650 ft., and continued pumping has failed to more than temporarily lower it. This evidently establishes the water level of the camp, for above it the mines are dry. The ore occurs chiefly as lead sulphide, with quartz gangue, filling fractures in limestone, which is underlaid by quartzite and intruded by masses of monzonite, and later, much of it buried by flows of rhyolite and andesite. All the important ore deposits are confined to the limestone, with the exception of a few mines in an intrusive rhyolite, near Silver City. A number are close to the contact, particularly in the Beck tunnel, which, though nearing the contact, to date has opened no ore other than that in the limestone. There are no important lead-silver mines on the lime-igneous contact. The Eureka Hill mine, at Eureka, is being profitably worked by lessees, as is also a part of the Bullion-Beck, in which Superintendent L. C. Doty is working 40 men on company account. Here the main shaft is down 1,300 ft., with levels every 100 ft. The 500-ft. level has been run 3,000 ft., and at its end a shaft sunk 500 ft. and raised 300 ft. A 40-h.p. air-hoist placed in the tunnel station handles the rock from these eight levels by an ingenious arrangement of sheave wheels. The principal company work is confined to prospecting for copper.——At the Eagle and Blue Bell, Superintendent P. S. Williams is working on company account, shipping regularly.——The Little Chief is being worked by Joseph Hanophan, and the Tetro mine, under the superintendence of John Strong.——J. B. Evans has charge of underground work at the Snowflake.——There is but one mill in operation in Tintic district. This is the Uncle Sam at Knightville, near Eureka. Here the ore is crushed, classified and concentrated, the concentrates being shipped to the smelter. C. C. Griggs is superintendent of mine and mill.——Adjoining the Uncle Sam, the Godiva Mining Co. is building a new mill employing the Sherman system of water classification, which is expected to be ready by April 15.——At the May Day mine Superintendent H. M. Eakin is drifting on the 300 and 500-ft. levels from the 500-ft. shaft at the end of an 800-ft. tunnel. He has 30 men at work.——The Yankee Consolidated mine is being worked under the superintendence of B. N. Lehman, and the Beck tunnel by John Roundy.——At Mammoth, the working mines include the Ajax, Thomas Weir, president, and T. Patience, superintendent; the Lower Mammoth, Wm. Balls superintendent; the Mammoth, S. McIntyre superintendent; the Grand Central, C. E. Loose manager and P. Donnelly superintendent; the Black Jack, John Roundy superintendent; the Carisa, E. Hofman superintendent, and the Star Consolidated, J. P. Turner superintendent. A little work is being done near Silver City on the Swansea and South Swansea under the direction of S. C. Ware and Roan Wheeler, respectively. The Dragon iron mine, above Silver City, is being worked under the direction of L. E. Riter.

Eureka, March 12.

Salt Lake County.

The Bingham Metals Co. will instal a compressor at its mine in Pine canyon, near Bingham.

Summit County.

The Magnolia-St. Louis Mining Co. will instal a hoisting plant at its mines, near Park City.

Tooele County.

The Stockton Gold Mining Co. reports a strike of galena on the 850 ft. level on the Black Bear contact, near Stockton. Work will be resumed on the 500, 600 and 700-ft. levels.——In the Delmonte ground of the Scranton, near Delmonte, a new 1500-ft. tunnel is to be run to tap the Delmonte orebodies. The development of this portion of the property will be entirely through this tunnel.——H. J. Heermans, of Scranton, Pa., is now at the Scranton mine, near Delmonte, installing the engines and machinery recently purchased by the company.——C. W. Clark, of the Overland Gold Mining Co., has deeded to D. Blanchard, of Boston, the Sundown group of fourteen claims, in Tooele and Utah counties, together with machinery, tools, etc.

WASHINGTON.

King County.

A stamp-mill and concentrating plant for the instruction of students in metallurgy will be in working order on the campus of the University of Washington at Seattle within a month. Most of the work on the plant is being done by the students.

Kittitas County.

The Washington Quicksilver Co.'s mine near Ellensburg is ready for machinery and will be developed in the near future. The ore will be treated on the property by a 50-ton plant driven by electricity.

Okanogan County.

Development on the Leadville property near Loomis will be started soon.——Development will be started by the Copper World Co. on its property near Loomis.——It is reported that the Last Chance mine, formerly the Ruby mine, in Ruby district near Ruby, will be worked during the spring and summer. Ore shoots are being opened up by tunnels.——The Arlington mine near Ruby, will be equipped with machinery during the spring. The workings will be extended 300 ft. deeper.

Snohomish County.

M. Nisel, one of the refiners at the Everett smelter, who was arrested charged with stealing bullion last week, has confessed the theft and has revealed the hiding place where most of the stolen bullion was concealed.

Stevens County.

The British Columbia Copper Co. has installed a five-drill Rand compressor and a 50-h. p. boiler at the Napoleon mine at Boyd's, near Marcus. The ore from the mine is being shipped to the company's smelters in British Columbia.

The Hibernian Gold and Mining Co. will resume operations on two claims in the Pierre Lake district, 130 miles north of Spokane and near Hughes siding.——The American Flag Mining Co. will resume work on April 1, at the American Flag and Knob Hill mines one and one quarter miles from Rock Cut on Kettle River.

Whatcom County.

It is given out at Bellingham that the Copper-Lead Smelting Co. has temporarily abandoned the building of a smelter near that place, owing to its failure to secure a suitable site.

FOREIGN.

CANADA.

Consul Harvey, of Fort Erie, says that Canada is producing more nickel than all the rest of the world. The opening of Canadian nickel mining was the result of a $2,500,000 Cleveland concern starting mines in 1886 at Copper Cliff for copper. This was sent to New Jersey reduction works, where the nickel was run off in the slag as worthless. Soon after it was discovered that the nickel in the ore was valuable, and the ore now contains 12 lb. per ton, worth 40c. per pound—$4.80; 2½% copper, 50 lb. per ton, worth 15c. per pound, $7.50; 40% iron, and 30% sulphur. The International Nickel Co. now owns 20,000 acres of nickel lands, including the original Cleveland company's, and produces 700 tons of nickel matte daily, which goes to New Jersey refineries. Their output amounts to over $1,000,000 annually. There are also other mines in the Lake Superior region.

The preliminary report of the Geological Survey of Canada shows the mineral production of the Dominion during 1905 to have been $63,574,707, as compared with $60,073,897 during 1904. The largest items for 1905 were the output of gold, totaling $14,486,833; of coal, $17,658,615; of nickel, $7,550,520; and of copper, $7,420,451. The gold production of the Yukon shows a decrease of $2,172,800, and the gold from elsewhere an increase of $197,116. Copper increased $2,117,875; lead, $1,016,683; nickel, $3,331,373; silver, $1,558,862; coal, $1,066,384; portland cement, $625,748.

BRITISH COLUMBIA.

The mineral production of British Columbia during ten years, 1896–1905, is of interest to the mining industry:

Year.	Total Value.
1896	$ 7,567,950
1897	10,135,268
1898	10,667,561
1899	12,335,131
1900	16,314,751
1901	20,000,580
1902	17,486,550
1903	17,495,594
1904	18,977,359
1905 (estimated)	21,203,000
Total for ten years	$152,857,250

The production during 1905 was as follows:

Gold	$ 5,780,000
Silver	2,015,000
Copper	5,430,000
Lead	2,268,000
Zinc	320,000
Total metalliferous	$15,913,000
Coal	3,330,000
Coke	1,210,000
Building materials, etc	750,000
Total non-metalliferous	$5,290,000
Summary—	
Metalliferous	$15,913,000
Non-metalliferous	5,290,000
Total production	$21,203,000

Boundary District.

Estimates show the following numbers of men to be employed in the mines: Granby mines, 425; Mother Lode, 130; Brooklyn-Stemwinder, 150; Rawhide, 20; Sunset, 25; Emma, 25; Oro Denoro, 25; Pathfinder, 20; Betts & Hesperus, 5; Jewel, 5; Providence, 35; Skylark, 18; Last Chance, 8; Elkhorn, 5; Helen-Strathmore, 15; Prince Henry, 5; Preston, 5; Sally, 15; Rambler, 5; Washington-Idaho, 5; North Fork mines, about 25; West Fork mines, about 25; various small properties, about 50; total, 1,046.

At the smelters as follows: Granby smelter, 350; British Columbia Copper company's smelter, 100; Dominion Copper company's smelter, 150; total, 600.

The Boundary mines for the week ending March 10 shipped as follows: Granby mines to Granby smelter, 18,268 tons; Mother Lode to British Columbia Copper Co. smelter, 3,488 tons; Brooklyn-Stemwinder to Dominion smelter, 3,926 tons; Rawhide to Dominion smelter, 233 tons; Sunset to Dominion smelter, 970 tons; Mountain Rose to Dominion smelter, 206 tons; Emma to Nelson and British Columbia Copper Co. smelters, 375 tons; Oro Denoro to Granby and Dominion smelters, 462 tons; Providence to Trail smelter, 30 tons; Skylark, 40 tons; total for the week, 27,998 tons; total shipments for the year, 240,289 tons. The three district smelters this week treated the following tonnage: Granby smelter, 17,176 tons; British Columbia Copper Co. smelter, 4,525 tons; Dominion smelter, 5,514; total for the week, 27,215 tons; total treatment tonnage for the year to date, 247,418 tons.

G. H. Collins and W. T. Hunter have taken a working bond on the Washington and Idaho claims, on the west fork of Kettle river, near Phœnix.——At the Granby smelter furnace No. 6 is being changed and the management will try the experiment of placing the down-take pipe in front instead of at the rear of the furnace. The new tramway for conveying converter slag was completed and put in operation last week.——A 20-h.p. electric hoist has been ordered for the Prince Henry mine, near Greenwood. The shaft, down 140 ft., will be continued 150 ft. farther.——T. T. Muller, of the Chicago & British Columbia Mining Co., will resume operations on the Don Pedro mine, two and one-half miles from Phœnix.——Work began last week on a number of improvements at the Skylark mine, near Phœnix. These include a new shaft-house, 150-ton ore bins and a dry room.——The work of deepening the main shaft at the Mother Lode mine, near Phœnix, began last week. The owners of the Elkhorn mine, near Phœnix, will sink 100 ft. farther.——Five air-drills are now being operated at the Rawhide mine, near Phœnix.

Yale District.

A company of New Zealand men has leased three miles of the bed of the Fraser river, below Yale, on which they will build a large dredge. Manager Williams will have charge of the construction of the dredge.

FRANCE.

A dispatch from Paris, on the 10th inst., contained the following: An explosion of fire damp at 7 o'clock this morning carried death and destruction throughout the network of coal mines centered in Courrieres and fire followed the explosion, making rescue difficult and almost impossible. The excitement and confusion in the vicinity prevented early estimates of the exact loss of life, but a dispatch received here at 4 p. m. gave 1,404 miners entombed and probably lost. Later dispatches give more than 1,200 dead.

MEXICO.

Senor Manuel Diaz Barriga, of the Financial Agency of the Mexican Government, has made the following statements concerning the results of the new mining laws of Mexico: The taxes that were raised directly upon the production of precious metals were as follows: (1) The internal stamp tax, which represented 3% on the value of gold and silver; (2) the coinage tax, which was equivalent to 2% on the value of gold and silver; (3) the assay, smelting, separating and refining taxes, according to various tariffs; (4) the title to mines tax, which consisted of a payment of $10 per pertenencia; (5) the local taxes on precious metals, the maximum of which was 2% on the value of the said metals. In accordance with the new legislation, these taxes and dues have been subject to the following modifications: (1) The internal stamp tax has been fixed at 3½, 2½ and 1½%, according to whether the metals were in their natural state, or had been treated, or had been treated and refined; (2) the coinage tax has been abolished; (3) the title to mines tax has been reduced from $10 to $5 per pertenencia; (4) the annual tax has also been reduced from $10 to $6 per pertenencia, and in some instances to $3; (5) finally, the local taxes cannot exceed in future 1½%, and this reduction of 25% signifies a diminution equal to the respective Federal tax. The Executive, desiring further to relieve the mining industry, freed from import duties the principal articles, coming from abroad, used in the mines or for the treatment of metals, although some of these exemptions are only of a temporary character. According to calculations made as regards the production of the last fiscal year, the reductions of the taxes and dues that have been decreed will cause a sacrifice to the Federal budget of close to $4,000,000 annually. This loss may be distributed in the following manner: Calculating on a production of gold and silver of $105,000,000 (of which $10,000,000 will pay 3½%, $80,000,000 2½%, and $15,000,000 1½%), the stamp tax will produce less than it produced in 1903-4 by $575,000; the amortization tax abolished, $1,550,000; the reduction of the title tax, $300,000; the reduction of the annual tax on pertenencias, $725,000; the reduction of the Federal tax on the local taxes that are raised on mining, $200,000. Calculating what the Government will lose by the abolishing of the import duties on certain articles used by the mining industry at $250,000, the resulting total is $3,600,000.

Chihuahua.

W. K. Ryan has bought 250 pertenencias, at Los Plomosas, a zinc camp, six miles from San Sostenes station, on the Kansas City, Mexico & Orient Railroad. Large amounts of zinc ore have been shipped from the camp to smelters in the United States during the past 10 or 12 months.

Manuel Gameros is sinking a new shaft on the Juarez mine, in Santa Eulalia. It is down 118 m. and will be continued to 200 meters.

Leopoldo Iwonsky, manager of the House of Stallforth, in Parral, reports the sale of the Descubridora & Raya mines of J. F. Johnston and Bert Peterson, in the Buena Vista section of Santa Barbara camp. The purchasers are W. B. Thompson and associates, of New York. Mr. Peterson is retained as general manager. The purchasing company has also taken over W. V. Pettit's mill, on his Adela mine, near the properties purchased. This mill is to be remodeled and enlarged, and the process changed from amalgamation to cyanidation.

Thompson and associates have taken an option on La Paz mine, adjoining the Raya & Descubridora.

At Ocampo, a strike is reported in the Watterson mine of the Watterson Gold Mining Co., in the lower tunnel, where an 18-in. streak was cut, which runs over $500 Mexican per ton and the entire six feet runs $100 per ton.

A. B. Fall, of El Paso, manager of the Greene interests in Chihuahua, states that W. C. Greene has bought for the Gold-Silver Co. the Santa Eduwiges mine in Ocampo district from Governor Enrique C. Creel and Ketelsen & Degetau, of Chihuahua City. This is an old gold-silver mine, which was worked at one time by H. A. W. Tabor, of Denver.

Guanajuato.

C. W. Van Law, general manager of the Guanajuato Reduction & Mines Co., has gone to Mexico City to take legal action in the fight against the agents of the MacArthur-Forrest people. It is stated that the Guanajuato Consolidated Mining & Milling Co., the Peregrina Mining & Milling Co. and the Guanajuato Amalgamated Gold Mines Co. will join with the Guanajuato Reduction & Mines Co. It is understood that the Guanajuato Consolidated Co. has been operating its cyanide plant for more than a year without the authorization of the MacArthur-Forrest people.

Jalisco.

The San Rafael mines at Tapalpa have been transferred to the San Rafael Mining Co., of Mercer, Pa. The latter company has contracted for new equipment at the mine and is figuring upon the installation of a 50-ton reduction plant.

Monterey.

The owners of the Higueras mine, between Monterey and Saltillo, will construct a railway from the mine to the National Railroad, a distance of four miles, and will put in cables and tramways for transportation of ores.

Oaxaca.

The Veronica group of gold and silver mines at Tavache has been sold to H. J. Beemer, of New York.

J. Prim and R. Wilson have bought the Santa Maria claims, near Zacualpan. Development work has been begun, a shaft and tunnel having been started.

San Luis Potosi.

An official report gives the yield of 137 mining properties, covering 7561 hectares of land in this State during the year 1905, as 88,018,014 kg. of ore, producing $3,323,152. These properties include gold, copper, silver and iron mines.

Sonora.

(Special Correspondence).—The Calera mine, of the Ohio-Mexican Mining Co., at Coborca, has completed a 100-ton smelter built by the Colorado Iron Works. They have blown in.—— The surveyors are in the field now laying out a railroad to Point Lobos on the coast of the Gulf of California. One of Prof. Grendell's party that was lost between here and the coast was finally found by fishermen on the coast, but was crazy. Four hands of white men are reported to have been found nailed to a tree with wooden spikes near the place where Grendell's party disappeared, but these are supposed to be those of two men from Yuma who disappeared two years ago. Grendell's party had not reached Tiburon island as was generally reported. They planned to prospect the coast and possibly to cross the ford which the Seri Indians use to reach Tiburon island at low tide. They disappeared 25 miles from Poso Coyote, a spring near the coast. It is generally supposed the Papago Indians killed the Grendell party.

Guaymas, March 10.

The Wisconsin-Mexican Mining Co. will start work at the Plomosa mill and mine, which have been shut down for some time. This property was formerly owned by Dr. Toussaint.—— R. Graham, who owns La Colorado gold property, at the same place, has organized a company which will take over the property and put up a 10-stamp mill.

E. D. Brigham, of the Banco del Oro mine, at Magdalena, reports that the new 120-stamp mill is completed. The mill will be operated by electric power from Magdalena.

The Llano de Oro Co. is putting a 50-stamp mill on its property near El Oro in the Altar district. It is given out that the company will spend in the neighborhood of $1,000,000 in improvements before beginning actual mining and milling.

SOUTH AMERICA.

CHILE.

Consul Winans, of Iquique, states that the Chilean nitrate producers' combination is off, the agreement expiring on March 31, when it was expected that it would be renewed for another five years, but some manufacturers are not willing to agree to their quota of output, though all agree that 2,000,000 tons is all that will be consumed this year. It was desired to restrict the production to this amount, while the production may otherwise run up to 2,400,000 tons. This would cause a drop in price in 1907, unless the consumption increases. During the first 10 months of 1905 the consumption of nitrate of soda was 1,584,000 tons, compared with 1,455,000 tons during the same period of 1904. The failure to renew the combination is considered a serious matter here, and the Chilean minister of interior has requested a conference with the manufacturers, in order to effect an agreement; but the producers are of the opinion that nothing could be done at such a conference, and will probably not accept the invitation.

Books Received.

Report of the Reclamation Service for 1903-04, with accompanying maps, issued by the United States Geological Survey. The work deals with the various projects in the several States, each being fully described and illustrated.

'The Lead and Zinc Deposits of Wisconsin,' is the title of Bulletin No. XIV of the Wisconsin Geological and Natural History Survey. The volume has been written by U. S. Grant, and deals in an interesting manner with the geology, the ore deposits, and the methods of mining and treatment. The report is accompanied by numerous topographical maps. Published at Madison, Wisconsin.

'Bulletin of the School of Mines,' Golden, Colo., for January, 1906, contains a number of interesting papers, among them being: Concrete Foundation Floors; Legitimate v. Illegitimate Mining; Practical Points on Mine Surveying; Methods of Precipitation in the Cyanide Process, and Tungsten in Colorado. The latter paper is one of the most valuable and complete papers on the subject that has been published.

'Steam Turbines' is the latest contribution to this important subject. This volume, by Carl C. Thomas, contains 286 pages, with numerous plates and illustrations. The author has devoted himself to the setting forth of the essential principles of steam turbines rather than to those features of purely scholarly interest. To those interested in steam turbines the work will prove of great interest and value. John Wiley & Sons, New York. Price, $3.50.

'The Miner's Manual' is the latest contribution to this class of literature. The title seems unfortunate, as it leads one to believe it to be a treatise on practical prospecting and mining, whereas it deals almost wholly with the mining law. In this field it fills to some extent a wish of the miner who desires an inexpensive work on the relation of the law to the miner. The book takes up the various subjects—discovery, location, title, posting notices, recording, etc., and then the miner's rights. There are numerous blank forms and also a glossary of mining terms. Price: Buckram, $2.50; in sheep, $3. The book will be sent by the MINING AND SCIENTIFIC PRESS upon receipt of the price. Lowman & Hanford Stationery & Printing Co., publishers, Seattle, Washington.

'Electric Power Transmission' is the title of a handsome volume on this important subject, by Louis Bell, Ph. D. This is the fourth edition of this valuable treatise, which in itself is a simple indication of the favor with which the book meets. The work deals with the elementary principles of power transmission, the general conditions under which it is accomplished, and the operation of both continuous and alternating currents. A chapter is devoted to the hydraulic development of electrical energy, as well as by other means, and much attention is given to the line, its construction, materials and methods of distribution. There are numerous valuable and accurate tables for the use of the electrical engineer in the volume, as well as many excellent illustrations. McGraw Publishing Co., New York City. Price, $4, net.

Obituary.

SAMUEL J. HENDY, president of the Joshua Hendy Machine Works of San Francisco, died at his home on Wednesday, the 14th inst., of heart failure, after a short illness. SAMUEL HENDY was one of the best known and most popular mining men of the West. He had grown up from boyhood in the business of which he finally became the head. He was prominent in politics and a member of the Masonic and Odd Fellows fraternities, a colonel on the Governor's staff, and for years treasurer of the California Miners' Association. He was born in South Carolina in 1855. He had an attractive personality and was always a genial companion, he will be greatly missed and mourned by a host of friends.

M. E. SMITH, well known in Colorado as a sampling works and smelter manager, died at Denver last week, aged 65 years.

Personal.

D. O. MILLS is in San Francisco.

PERCY L. FEARN is at Boise, Idaho.

THEODORE DWIGHT is at Guanajuato.

J. H. KINKEAD is at Goldfield, Nevada.

J. PARKE CHANNING is at Los Angeles.

G. H. NICHOLS is at El Transito, in Honduras.

W. F. FERRIER, of Rossland, is in San Francisco.

T. G. MADGWICK has returned to London from Baku.

JOHN HAYS HAMMOND is expected in San Francisco.

WILLIAM B. DEVEREUX is at Camden, South Carolina.

J. E. SPURR is examining the Sirena mine at Guanajuato.

H. L. WEBSTER has returned to London from West Africa.

ROY H. CLARKE is examining mines at Douglas, Arizona.

ARTHUR WINSLOW is in San Francisco on his way to Goldfield.

H. L. SLOSSON has returned to San Francisco from Goldfield.

JOHN H. LUCAS, recently on the Rand, has gone to Rhodesia.

ALEXANDER BURRELL, of Montana, is at Berkeley, California.

JOHN B. FARISH is in San Francisco, on his return from Mexico.

E. GYBBON SPILSBURY has returned to New York from London.

F. L. BOSQUI has moved his office to 633 Mills Bdg., San Francisco.

GORDON LAND, of Grants Pass, Oregon, is visiting San Francisco.

G. LAVAGNINO has returned from Pasadena, Cal., to Salt Lake City.

E. FLEMING L'ENGLE is visting New York from Prescott, Arizona.

CHARLES JANIN sailed from New York by the *St. Louis* on March 10.

H. DE C. RICHARDS has returned to San Francisco from Virginia City.

T. A. VARDEN, of Kennett, has been in Nevada county during the past week.

S. A. WORCESTER, of Cripple Creek, is at Leadville on professional business.

D. SHANKS is manager of the Almoloya Mining Co., near Chihuahua, Mexico.

W. MURDOCH WILEY has been on a visit to Zacatecas from Guanajuato, Mexico.

C. A. RANDALL is superintendent of the Davis group, 16 miles from Prescott, Arizona.

JOHN J. MCKINIRY, a mining man of Ward, Colorado, is in New York for a week.

GEORGE J. BANCROFT is examining mines in the Altar district, of Sonora, Mexico.

H. L. GROSSBAUCH is now assayer for the Eureka-Richmond Co., at Eureka, Nevada.

ARTHUR H. HALLORAN, of the MINING AND SCIENTIFIC PRESS, is at Butte City, Montana.

W. G. SCOTT, formerly at Bingham, is now with the Arizona Copper Co., at Morenci, Arizona.

FORBES RICKARD is at the head of an exploring party in the Yaqui River county, northern Mexico.

C. M. PERRY, of Boston, connected with the Newark Mining & Milling Co., Nevada, is at the Palace Hotel.

J. B. TYRRELL, formerly of Dawson, is at Quebec attending the meeting of the Canadian Mining Institute.

S. HERBERT WILLIAMS is managing director of the Shawmut Consolidated Copper Co. at Bingham, Utah.

ROBERT W. HUNT, of Chicago, has been elected president of the American Institute of Mining Engineers.

C. W. PURINGTON, who has been examining mining property near Wickenburg, Arizona, has returned to Denver.

A. E. KEABLES has resigned from the management of the Old Union Mining & Milling Co., at Breckenridge, Colorado.

F. W. ROYER, of Mexico City, and HARRY A. LEE, of Denver, have been examining mines in the Sta. Eulalia district, Chihuahua.

H. W. B. HOWARD has been appointed assistant secretary of the American Institute of Mining Engineers in succession to THEODORE DWIGHT.

E. C. CONNERY, of Minneapolis, visited the Continental mine, at Vulcan, Colorado, and subsequently visited Los Angeles and San Francisco.

NEWTON W. EMMENS has been appointed consulting engineer to the Tinworkers Gold Mining Co. (Ltd.), at Camborne, Lardeau district, British Columbia.

JAS. D. SCHUYLER, as consulting engineer, and GEO. S. BINCKLEY as chief engineer, are at Monterey, Mexico, constructing a system of water supply and drainage.

W. H. SHOCKLEY has purchased a large interest in the Shoshone Annex Mining Co., owning adjoining ground to the famous Montgomery-Shoshone mine lately bought by CHARLES M. SCHWAB.

BONE ASH.—Extra No. 1, 6c ℔ lb; No. 1, 5c½.

BORAX.—Concentrated, 9½c ℔ lb; powdered, 10c; fused, 25c; crystal, refined, 8c.

CANDLES.—Standard Oil Co.—Electric light, 16 oz., 11c; 14 oz., 9¾c; 12 oz., 8½c; 14 oz., 7¾c; Hotel, 12 oz., 9c; Granite (mining), 16 oz., 11½@11¾c; 14 oz., 10@10½c; 12 oz., 9½@9¾c; 10 oz., 8½c; Paraffines, White, 1s, 2s, 4s, 6s, 10½c; 12s, 11c; colored, 1c higher; Radiant Paraffines, 4s, 6s, 14 oz., 9½@9¾c; 10 oz., 7¾c.

CAPS.—3x, $5.50@6 per 1000; 4x, $6.50@7; 5x, $8@8.50; Lion, $9@9.50, in lots not less than 1000.

CHEMICALS.—Cyanide of potassium, 98%–99%, jobbing, 23@24c ℔ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 3@3½c ℔ lb.; caustic soda, in drums, 3@3½c ℔ lb.; Cal. s. soda, bbls., $1.10@1.20 ℔ 100 lbs.; sks., 90c@$1.00; chlorate of potash, 12@13c; nitrate of potash, 6¾@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2¼@2½c; powdered sulphur, 2¼@2½c; flour sulphur, French, 2¼@—c; alum, $2.00@2.25; California refined, 1¾@2c; sulphide of iron, 8c ℔ lb.; copper sulphate, 6¼@7c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66% B, 1¾@2c ℔ lb.; nitric acid, carboys, 8c ℔ lb.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1**, 50%, carload lots, 11¾c; less than one ton, 13¾c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2**, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

COAL.—San Francisco, coast, yard prices to dealers: Wellington, $7.50; Seattle, $6.50; Coos Bay, $5.50; Cargo lot, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $14.00; Cannel, $8.50; Rock Springs, $8.50, long ton; Colorado Anthracite, $14.00. Coke, $11.50 per ton in bulk, $13.00 in sacks; Sunnyside, $8.50, long ton.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $18.35; gray forge, $17.85; San Francisco, bar, 3½c. ℔ lb., 3¾c. in small quantities.

STEEL.—Bessemer billets, Pittsburg, $27.00 open hearth billets, $28.00; San Francisco, bar, 7c to 13c ℔ lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 8½c.; less than 500 lb., per lb., 8½c.; in 25-lb. tin pails, ½c. ℔ lb. above keg price; in 1 and 5-lb. tin cans, 100 lb. per case, ½c. per lb. above keg price. Dry Lead.—In bbl., 1 ton and over, 8c.; do. in kegs, 8½c.

LIME.—Santa Cruz, $1.35 country, $1.25 city ℔ bbl.

CEMENT.—Imported, $3.00@4.00 ℔ bbl.; California, carload lots, $1.80 f. o. b. at works; small lots, $2.10 ℔ bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

LUMBER.—(Retail): Pine, ordinary sizes, $24.00@25.00; extra sizes higher; redwood, $28.00@30.00; lath, 4 feet, $4.50@5.00; pickets, $21.00; shingles, $2.50 for No. 1, and $2.25 for No. 2; shakes, $13.50 for split and $15.00 for sawed; rustic, $28.00@35.00.

NAILS.—This week the basic prices are: Wire, $1.85; Cut, $1.75. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d, Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4d and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

OILS.—Linseed, boiled, bbl., 56c; cs., 61c; raw, bbl., 54c; cs., 59c; Lucol oil, boiled, bbl., 48c; cs., 53c; raw-bbl., 46c; cs., 51c. Kerosene—Pearl, per gal., 17c; Astral, 17c; Star, 17c; Extra Star, 20c; Eocene, 19c; Elaine, 26c; Water White, in bulk, 10½c; Mineral Seal, iron bbls., 18½c; wooden bbls., 21c; cs., 24½c; Mineral Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 15½c, do., cs., 22c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 12½c; do., in cs., 19c; Lard Oil, E. W. S., bbl., 65c; cs., 70c; Neats-foot Oil, pure, bbl., 63c; cs., 78c; Sperm, crude, 53c.; Natural White, 68c; Bleached, do., 57c; Whale Oil, cs., 57c.

BISMUTH.—Subnitrate, ℔ lb., $2.10.

CHROMIUM.—90% and over, ℔ lb., 80c.

FIRE BRICK.—Domestic, carloads ℔ 1000, f. o. b., factory square, $25.00; soap and split, $22.50; arch and wedge, $27.50; skewback, $30.00; circle, $32.00.

FIRE CLAY.—Domestic, ℔ ton 2000 lbs. in 125-lb. bags double, and dry ground, f. o. b., factory, $8.50.

FUSE.—Triple tape, $4.00 per 1000 feet; double tape, $3.55; single tape, $3.10; Hemp, $2.85; Cement No. 2, $3.10; Cement No. 1, $2.75, in lots of 3000 and up.

LITHARGE.—Pure, in 25-lb. bags, 9½@10½c ℔ lb.

MAGNESIUM.—Pure, N. Y., $1.60.

MANGANESE.—Black oxide, ℔ lb., 2¾@4c.

MERCURY.—Bichloride, ℔ lb., 77c.

MOLYBDENUM.—98@99% N. Y., $1.75 ℔ lb.

PHOSPHORUS.—American, ℔ lb., 70c.

RED LEAD.—500 lb. and over at one purchase, ℔ lb., 8½c.; less than 500 lb., 8½c.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 54c.

SODIUM.—Metal, ℔ lb., $1.

TUNGSTEN.—Best, ℔ lb., 90c.

URANIUM.—Oxide, ℔ lb., $3.40.

Commercial Paragraphs.

SYDNEY C. MYERS, representing G. W. MYERS, of the Chrome Steel Works, is in Mexico and Arizona and reports good business.

THE Bucyrus Co. of South Milwaukee, Wis., is building 61 steam shovels, three railroad wrecking cranes and one railroad pile driver for work at Panama.

THE Madison Lead & Land Co., of Fredericktown, Mo., has been making additions to its equipment in a No. 51, 10 by 12-in., double-cylinder, double-drum, link-motion hoisting engine, and two double deck slime tables, 18 ft. diam., furnished by the Allis-Chalmers Co., Milwaukee.

THE Bullock Electric Manufacturing Co., of Cincinnati, Ohio, have placed an order with the Electric Cable Co., 42 Broadway, New York, for the new insulating compound, voltax, for impregnating field and armature coils. It is cheaper than rubber insulation, and with the increase in the price of pure rubber this new material is coming into use.

THE Colorado Iron Works Co., of Denver, has the contract to furnish equipment for a modern copper matting plant for the New World Smelting Co., of which G. L. Tanzer, of Seattle, Washington, is president. The plant will be erected on the latter's property, near Gardiner, Montana. The Colorado Iron Works Co. is also supplying the Pahaquarry Copper Co., of Bangor, Pennsylvania, with two sets 40 by 16-in., and four sets 30 by 10-in. C. I. W. Standard rolls; 22 impact screens, 13 of the latter having distributors.

THE Utah Mining Machinery & Supply Co., of Salt Lake City, J. E. Galigher manager, report the following recent sales of 'Callow' equipment: To the Hecla Mining Co., Wallace, Idaho, two duplex Callow traveling belt screens; to the Bunker Hill & Sullivan Mining Co., Kellogg, Idaho, one duplex Callow traveling belt screen; to the Nevada Consolidated Mining Co., Ely, Nev., two duplex Callow traveling belt screens and sixty-eight 8-ft. Callow settling tanks; to the Boston & Montana Mining Co., Great Falls, Mont., six 8-ft. Callow settling tanks; to the Tombstone Consolidated Mining Co., Tombstone, Ariz., six 8-ft. Callow settling tanks.

Trade Treatises.

Bulletin No. 2, of the Fulton Iron Works of San Francisco, is devoted to a description of a California gold mine and milling plant, and to some of the specialties of their manufacture.

Bulletin 51-C of the Sullivan Machinery Co., Exchange Place, Chicago, describes the Sullivan 'plug' drill for quarrying and similar work. Specific instances are given of the work performed with this time-saving tool.

The Leyner Rock Terrier drill is fully described in Catalogue No. 8 of the J. George Leyner Engineering Works Co., of Denver. This is a one-man drill, which the manufacturers claim operates with a minimum amount of air, with a relatively great drilling capacity.

EDITORIAL.

PROFESSIONAL MEN will join with us in thanking Mr. E. P. Mathewson for the comprehensive and authoritative reply which he has given, on another page of this issue, to the questions comparing blast furnace with reverberatory practice. Mr. Mathewson has had unique opportunities for such a comparison, being manager of the great Anaconda smelter. The publication of such information can do no one any harm and, obviously, it is of great value to earnest students of industrial metallurgy.

PRICES for copper at San Francisco do not vary much from those current at New York. Last year, when the metal was in demand by China, the price here was better than at New York; but the market is small and it is supplied by the refinery at Tacoma, which is able to ship its product by water. There is no other refinery west of Great Falls; even the great Washoe smelter, at Anaconda, sends its crude copper to be refined at Baltimore and Perth Amboy, in New Jersey. Nevertheless, as the Chinese demand for copper grows; and that from other countries in the Orient unable to get sufficient of the metal from Japan, the market at San Francisco should become of increasing importance.

THE article on recent progress in the Lake Superior copper region, by Mr. J. Parke Channing, records the first results of an important departure in milling practice. The substitution of rolls instead of steam-stamps is in keeping with the tendency of modern methods of concentration by water; indeed, we dare go so far as to say that as the cyanide annex increases in importance, and amalgamation becomes a smaller factor in the processes for treating gold and silver ores, the ordinary gravity stamp also is destined to make way for machines, which, while they do not permit of amalgamation, are better devices for pulverizing the ore preparatory to cyanidation.

Snowslides.

The series of snowslides which have brought devastation to a number of mines in southwestern Colorado represent an agency of destruction which is at work each spring, but with variable intensity. Of all evidences of Nature's power there is none so feared by the miner as this, "the awful avalanche." After the winter snows have fallen and, by successive thaws and frosts, have become packed, there comes, during the period marking the end of winter, a heavy snowfall which, settling and accumulating upon the hardened surface of the earlier precipitation, is ready to be launched down the steep slopes of the mountains with all the suddenness of a thunderbolt and all the confusing terrors of a whirlwind. A slight cause may disturb the uneasy equilibrium; even a mountaineer's foot-fall may cause a huge mass of snow to become detached. In the San Juan region of Colorado, where the mountain slopes are steep and but poorly protected by forests, there are more people killed each year from this cause than in Switzerland, although the man of leisure who risks his life climbing the Swiss heights usually receives more mention in the daily press than the miners and other humble individuals who lose their lives in the San Juan while going to and from their labor.

Ouray, Silverton, Telluride and Creede—all in the region formerly known as 'the silvery San Juan,' but now identified chiefly with profitable gold mining—are localities where snowslides are of yearly occurrence. One of the worst seasons in this regard was the spring of 1884, when a series of slides came down into the cañon of the Animas, below Silverton, so as to blockade the Rio Grande railroad to Durango. In 90 days only two provision trains managed to get through; for this was in the days before the rotary plough. Nowadays such prolonged interruption to traffic is unknown. In March, 1902, 18 men were killed at the Liberty Bell mine, above Telluride; the mill buildings were swept away and the tramway was severely injured. Since then the management of the Liberty Bell has built a V-shaped crib-work of solid timbers, filled with rock, in the path of the slide that did this damage; their foresight was rewarded during the present week, for the snow broke away as before, but the slide was divided by this obstacle and did comparatively little harm. The slide which smashed the Camp Bird mill is called the United States, because it annually descends in a ravine past an old mine of that name. Snowslides usually follow a line of destruction marked out by them in previous years, and indicated by the removal of trees, the presence of debris and the accumulation of piles of snow. The United States slide comes down a steep slope, it crosses the road to the mine, and descends into the valley traversed by the tramway, the towers of which are protected by a timber cribbing. The Camp Bird mill is a little over half a mile away and has never been visited by this slide. Above the mill are steep hillsides covered with pine, which were considered to indicate immunity from such danger. This year the mass of snow and the velocity of it were such as to carry the slide down the valley and over the edge of the hollow in which the mill stands, so that the vast body of snow dashed down the precipice and broke the mill building like an egg-shell. It was a similar supposed immunity from danger which caused the Liberty Bell catastrophe; for, of course, the buildings were erected at a spot confidently believed to be beyond the range of any slide.

These occurrences are often fatal to miners and prospectors, they are too sudden to be escaped even by the experienced. In the cemeteries at Telluride and Silverton are many large graves inclosing the remains of groups of unfortunate men who have been swept into eternity by the fearful avalanche. Such happenings have incited the hardy people of the region to many deeds of heroism; indeed, almost as many losses have occurred among rescue parties as among those first entombed. A pathway once made smooth by a slide is apt to be followed by a further descent of snow; a succession of slides will occur.

There is only one way to avoid the danger; for buildings, not to erect them at the foot of snowclad slopes; and for men, not to go abroad on the mountains just after a fresh snowfall, especially when it comes on top of a hardened surface. But even the greatest care is insufficient, as we have seen, and so long as the mountains raise their proud heads to heaven they will occasionally shed their white mantles so as to overwhelm the men who invade them in quest of gold.

An Interesting Prospectus.

Many absurd things are done in the name of mining, but unless they serve as a text for serious comment, we rarely make reference to them in these columns. The prospectus of the Cyanide Gold Mining Company, however, deserves notice. Starting with the statement of a fact, namely, the world-wide use of potassium cyanide for the recovery of gold, the writers of this document use a metallurgical name for a mining proposition because they possess "millions of tons" of ore suitable for cyanidation. The estimate is stated as thirty millions at one place and as 80,000,000 tons "by measurement" elsewhere in the prospectus. But to men of such large affairs, what does a million or two matter? The fact is "substantiated" by the sworn statement of a notary public, who has resided for several years in the neighborhood of the Homestake mine and is therefore a fit and proper person to certify as to the value of a mine in Oregon. This notary public concludes that "the properties of the Cyanide Gold Mining Company present a far better showing as a mining proposition than do the mining properties of the Homestake Mining Company (and every one that knows the Homestake properties knows that they are hard to beat)." The latter part of this assertion is probably true, the former is open to reasonable doubt. Several other sworn statements follow. Methinks these gentlemen do protest too much. Two of the affidavits are made by assayers, who quote altogether five assays on which the estimate of "millions of tons" is securely based. Then follows a comparison with the Alaska-Treadwell mine, it being emphasized that this famous mine has paid dividends of $7,485,000 on a capital of $5,000,000, while the capital of Cyanide Gold is only $500,000; therefore, of course, the shares of the latter are worth ten times as much. There can be no question of that.

Finally, that enthusiast on black sand, Dr. David T. Day, of the United States Geological Survey, is quoted in support of Cyanide Gold. Dr. Day is usually considered a clever man, but we doubt if he "has proven beyond a doubt that the black sands of the Pacific slope have a commercial value of $30 to $40 per ton." It is explained further that "only by accident did Dr. Day discover" the fact. This is rough on the learned Doctor, but it must be true, for the other

statements in this prospectus are also manifestly open to no suspicion of inaccuracy. The prospectus closes with a highly important assertion that "the immense deposits of cement gravel of the Cyanide Gold Mining Company contain about five per cent of black sand of a high grade, which carries rusty gold, platinum, rubies, garnets, zircon, monazite, rutile, titanic ore and magnetic iron, which makes the best quality of fine tool steel." Of course every schoolboy knows that potassium cyanide—the godfather of the company—is just the thing for the extraction of rubies, zircon and garnets from cement gravel, and we only regret one fact, and that is our misfortune in being unacquainted with the magnetic personality of the man who prepared these titanic statements.

The Fissure Vein.

There has been an interesting discussion of late, among geologists, as to the significance and utility of the term 'fissure vein,' and while apology has been made for that much abused, and often misunderstood, name, there has been more respect shown for it than might have been expected by anyone in touch with the trend of modern thought in that branch of geology allied to mining. Dr. R. W. Raymond holds that it is "a pity to break the continuity of technical literature by unnecessary killing of a familiar term," and he considers that by prefixing the adjective 'true' before 'fissure vein,' it becomes more useful by being made more definite. Mr. James F. Kemp, professor of geology, whose authority in such matters will not be questioned, states that whether we use 'fissure vein' or 'true fissure vein,' these terms mean a fault-fissure, because we cannot conceive of a fissure of the extent supposed without sufficient displacement to constitute a fault. Mr. J. E. Spurr, author of a well-known hand-book on mining geology, recognizes the existence of fissure veins, but confines his recognition of them to veins which have filled preexisting rifts, larger than cracks; and he does not recognize the popular attributes attached to the name, such as necessary deep-seated origin or necessary persistence in depth. Finally, Mr. Heinrich Ries, another authoritative writer on economic geology, defines the fissure vein as "a tabular mineral mass occupying or closely associated with a fracture or set of fractures in the enclosing rock, and formed either by filling of the fissures as well as pores in the country rock, or by replacement of the latter." The definitions are from *Economic Geology*.

We quote these expressions of opinion and expect that they will serve as an interesting subject for debate at many places within the sound of the whistle of a hoist or the laborious breathing of an air-compressor. The definition of fissure vein strikes at the very roots of our ideas of lode formation, for each man's interpretation will be colored by his notions of the manner in which ore deposits are formed. But we do not talk to ourselves, therefore the significance of a word in technical literature will be that given to it by those who read, no less than by those who write. We cannot precede each use of a term by a reiteration of our definition of it. 'Fissure vein' retains the significance given to it by the miners of the Hartz and of Cornwall, a hundred years ago, when geology was no more the science that goes by that name today than the old astrology is the astronomy of our time.

To this old term there still cling the ideas of theories now obsolete and you may take, and interpret the phrase as you will, the taint of those notions will cling round it still. A fissure was an open crack in the earth's crust, filled, according to Werner, from above; the Cornishman uses the word 'crevice' in place of fissure and he pronounces it like the French word *crevasse*, now largely restricted to the chasms made in the upper surface of a glacier. To him, and to other intelligent miners, a fissure or a crevice is a once yawning cavity now filled with ore; it originated by an earthquake shock or some other cataclysmic agent. Neither that comfortable word crustification nor that comprehensive term dynamic action, has served to fill the gaps in his own imagination of how these things happened. The use of 'fissure vein' by geologists links their ideas to his, by misunderstanding. It is interesting to hear professors and writers defining words in familiar use among miners, but their definitions never reach far enough to modify the meaning of words already accepted and deeply charged with a significance older than any standard text-book. There will be a failure to connect. Start a *new* term fairly on its career and it has a chance to retain its identity from the lecture room to the stope, but the words of the stope, once a part of the language, cannot be called upon to turn themselves inside out. The zebra can change his stripes more easily. 'Fissure vein' carries the meaning the miner has given to it for generations, and no symposium of geologists can change that.

Even the Judiciary, in those humorous performances known as mining lawsuits, has evolved a definition, specifically intended to be within the meaning of the acts of Congress. Justice Field has stated, in a memorable case, that "a fissure in the earth's crust, an opening in its rock and strata made by some force of nature, in which the mineral is deposited, would seem to be essential to the definition of a lode, in the judgment of geologists." Well, we have just quoted the latest scientific definitions, so let that go, but the remainder of his dictum is worth quoting because, although enunciated many years ago, it is continually being referred to in later litigation. He said: "To a practical miner the fissure and its walls are only of importance as indicating the boundaries within which he may look for and reasonably expect the ore he seeks. We are of opinion, therefore, that the term (fissure vein) as used in the acts of Congress is applicable to any zone or belt of mineralized rock lying within the boundaries clearly separating it from the neighboring rock." Such a definition includes everything from Dan to Beersheba, and affords glorious opportunity for claiming your neighbor's ore reserves.

Obviously, the only thing to do is to express modern ideas in terms that are unhampered by the baggage of discarded philosophies, not necessarily new words compounded of Greek and Latin, but English words not yet overworked in technology. Take 'fracture,' or 'rupture,' or 'break'; does the word 'fissure' as we use it today in mining mean—not by this man or that, but by general acceptance—much more than any of these? One man reads the word fault into fissure, another does not. One authority assumes the creation of an open cavity, another denies it. Well, can any break, rupture or fracture be said to have geologic existence until there has been movement of the two faces constituting their opposite sides? Until it becomes visible by reason of the disturbance of continuity, is it other than latent? It is conceivable that a rock pulled apart by tension may be fissured without vertical displacement of the opposing falls of the fissure, but such an occurrence does not come within the notion of continuity involved in a lode deposit; it may apply to a 'gash vein.' A fissure that is not a fault, no matter how slight the dislocation, has no existence in structural geology and is of no service whatever to that circulation of waters to which we impute the origin of ores. And if 'fissure vein' be a heritage from Von Cotta and De la Beche, authors who wrote on ore deposits before the geology of mining was out of its swaddling clothes, what shall be said of the 'true fissure vein,' which has been the catch-penny phrase of every irresponsible promoter from the year 1. The mere fact that Dr. Raymond, than whom no one could write with more authority, not only for ourselves but for those in Europe who read English technical literature—the mere fact that his dictum on the matter can only prove effective among a handful of men who already appreciate the harmlessness of the 'true' in modifying the misdirection of the 'fissure,' ought to suggest the impracticability of trying to re-christen a spurious infant, the bastard offspring of young science and blissful ignorance.

In conclusion, we quote from an advertisement appearing in the *Illustrated London News* of ten years ago; speaking of the Phœnix mine in New Zealand, it is said that: "It has been inspected and reported upon by several eminent engineers who have declared that the quartz lodes are true fissure veins, and in true fissure veins it is well known that there is no fear of giving out or not paying as depth is reached, the experience being that they get richer the farther they go down." A term that has been debased to such ignoble use is fit only for fakirs, spoofers and imposters; it has no place in scientific literature. It should be used charily even by mine promoters.

By the Way.

In a recent address before the University of Wyoming, Dr. Victor C. Alderson, president of the Colorado School of Mines, said: In scientific achievements the past century made more progress than all previous centuries combined. The latter half progressed more than the first half, while the last quarter was the most productive age for science that the world has ever seen. This may sound strange, but consider that it took 3,000 years to perfect the alphabet, and 450 years to mature the art of printing, yet 60 years have been sufficient to develop telegraphy, and it has only taken a few years to develop the application of the Roentgen rays and wireless telegraphy. Discoveries are made and applied more rapidly today than ever before. The discoveries of pure science have been marvelous, but not more marvelous than the manifold applications of these discoveries to the improvement and elevation of humanity. The reason for this is very simple, and is due to one simple fact. Of late our attention has been riveted upon war; the war in Africa, in Cuba, and in the Philippines. We may perhaps in a careless moment imagine that the war of armies is the only one of which account must be taken. But there is another warfare, bloodless to be sure, but quite as bitter, as relentless and as far-reaching in its effects as any war in Africa, Cuba, or the Philippines. I mean the unceasing contest for industrial supremacy. It is a war between classes of different nations, of different climes. The farmers of Russia, of India, and America, are all engaged in this ceaseless battle. It is a war of prices, a war for markets, for wealth, for industrial eminence. In these days business sagacity and ability must be re-enforced by the best educational and scientific opportunities. This is preeminently the age of the trained man; the untrained man is at a great disadvantage in trying to make a place for himself or to solve the problem of success. Superior education was once regarded as essential to the success of the professional man, but it was assumed that natural sagacity and alertness were sufficient capital for the business man. Under the conditions of modern life and the growing pressure of competition, it is now seen that special training is as necessary for men of affairs as for men of letters, law, or theology. Germany was the first nation to recognize this truth, and she has added to her already magnificent system of technical education high grade colleges of commerce. These are not what we know as commercial colleges, wherein the curriculum embraces penmanship, arithmetic, book-keeping, and the elementary routine of the counting room, but a high-grade college instruction, covering international law, economic history, tariffs, commercial geography, products, distribution, all the modern languages, aiming to fit men to take commanding positions in trade, in commerce, and in the consular service. The expansion of the United States will call for an increasing number of men so trained. Mr. James Bryce has noted that the average American regards himself as fit to occupy any office he can get. But surely the present tendency is strongly toward recognizing special training and special fitness for positions of trust. The coming generation should make careful note of this: the day of happy-go-lucky, adventurous fortune-hunting is past; the day of the specially trained man is here. Be prepared for your calling or you will invite failure. The world is not so wealthy of individual power, not so rich in intellectual might, that it can afford to neglect the opportunities of developing to full strength those seeds of power which frequently lie dormant and unsuspected among the young. Believe in culture! Believe in symmetrical development! But, above all, believe that the individual owes it to himself and to society to bring to full fruition those powers in which the individual excels! Too much emphasis is laid upon mere knowledge. The man who merely knows many facts is like the 'strong man' of the gymnasium. He is big, merely. The true physical athlete is no stronger than is consistent with grace, agility, and ease. The mental athlete is capable and successful not according to the number of facts he may command, but according to his habits of thought, the accuracy of his perceptions, and the development of his faculties. Failure to get on in the world is due not so much to lack of knowledge as lack of capacity to think, lack of zeal, of energy, of perseverance. More important than knowledge are well-trained ears and eyes and well-ordered physiques. With large numbers of men and women personal vigor and energy contribute very largely to their success, or its lack dooms them to failure.

The present is the golden age; we made a wise selection when we chose it—a selection excelled only by our young friends who choose to come a little later. Their problems will be different from ours. They will find that every calling is today demanding that its followers must be thoroughly trained. Careful and systematic training will supersede mere Chinese shrewdness in copying. Never have the unfit, the unskilled, the untrained been weeded out so relentlessly as they will be in the near future. The coming century will witness the greatest development of industrial forces that the world has ever seen.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and to give information dealing with the practice of mining, milling and smelting.

ANHYDRITE is calcium sulphate, but it is harder than gypsum.

AGRICULTURAL PATENTS have no extra-lateral mining rights.

BOTH placer and lode claims may be included in a single application for patent.

THE prospector should deceive no one—particularly himself, though often he does so.

CALCIUM occurs principally as carbonate or sulphate. It is never known to occur in nature uncombined.

THERE are millions of tons of low-grade ore in the dumps of the mines on the Comstock at Virginia City, Nevada.

THE miner's inch has been fixed by law in several States, notably California and Montana, at 1.5 cu. ft. per minute.

IN the case of re-location a new discovery is not necessary; but the notice must state that it is a re-location of the original.

THE origin of the Yosemite valley is in doubt. Some maintain it is of glacial origin; others that it is the result of block faulting.

RUTILE, a titanium oxide, is used principally to give a delicate yellow color to porcelain, and to tint false teeth bluish white.

A PROSPECTOR should banish all notions of how veins and formation should look, and take things as he finds them, investigating everything.

SOME of the early geological reports of the government—from 1860 to 1880—are to be found in second-hand bookstores and in most large public libraries.

THE twenty-first annual report of the United States Geological Survey, Part III, gives a comprehensive description of laccolites in the Black Hills of South Dakota.

OXIDATION of a vein or mineral deposit extends to a depth determined by conditions. This depth varies greatly in different districts and in mines in the same district.

THE most extensive deposits of uranium ores known to date are those in western Colorado and eastern Utah, in the La Sal mountains. The uranium bearing mineral is carnotite.

IT has been observed by scientists that a series of earthquakes is usually followed by a volcanic eruption. The active volcano may be near or distant from the region of disturbance.

IT is not the practice of hydraulic miners to clean up frequently, as it is an unnecessary expense. For this reason flumes should be securely anchored to protect them from floods.

A DIPPING NEEDLE may be used with success to locate deposits of magnetic iron, but the presence of magnetic bodies of either ore or metal, make the compass needle practically useless.

SULPHUR mixed with earthy matter occurs around the vents of many hot springs in California and Nevada. None of these deposits are at present being worked, so far as known to 'Concentrates.'

LIME is sometimes shipped long distances when a superior article can be made at home from limestone of the vicinity. A lime-kiln is one of the simplest and least expensive of things to build.

NO millman can afford to assume that he is saving all the values in his ore, or that he is doing the best that can be done until he proves by careful sampling and assay of tailing that such is the case.

ASSESSMENT WORK on unpatented claims done in this or any other year in excess of $100 counts nothing for the succeeding year. Wages paid a watchman cannot be considered as applying on assessment.

THE first essential of a legal mining location is a *bona fide* discovery. Next is the marking of the boundaries of the claim by cutting stakes or building monuments. Some States require further things as part of the act of location.

THE modern streams of California have cut channels as deep as 3,000 ft. below the ancient river beds, in some places, particularly the American river, near the eastern end of Forest Hill divide, and near Canada Hill, Bald Mountain and that section.

IF the ground at the bottom of the shaft crumbles, like rotten granite, the pump may be relieved of much of the grit by placing a coarse wire screen about the suction, in which the holes may be too large. Large amounts of grit cause the rubber valves to cut rapidly.

PROFESSIONAL PAPER NO. 38 of the United States Geological Survey, by J. M. Boutwell, gives a complete description of the mines of Bingham district, Utah. It may be obtained by addressing the Director of the United States Geological Survey, Washington, District of Columbia.

DAMS built across streams should be provided with a gateway at the lowest point through which the accumulated silt and sand may be occasionally washed away. If this be not done in time the area back of the dam will become completely filled with debris and the dam will have ceased to be of value.

THE discoveries which first attracted attention to the Cœur d'Alene district of Idaho were the placers on Pritchard creek, near Murray. Little mining for quartz gold was done in the district until lately. Now the gold-bearing veins are attracting attention, and new discoveries of importance are being announced.

THE earliest long-distance pumping plant in California known to 'Concentrates' was that from the Colorado river to the Paymaster mine, in San Diego county. This line was 17 miles long. It was in use about 1885, and was a success. Since that date pumping plants of this kind have been successfully installed in many places.

ALONG the foothills of California there is little if any sign of glaciation, but in the higher regions—6,000 ft. and upward—glaciated boulders and striations on exposed surfaces are numerous. Doubtless ice had much to do with the erosion of the higher altitudes, but if it affected the lower lands all trace of it has been effaced by subsequent milder climatic conditions.

IN the case of rotary mills, like the Bryan, Huntington, Chile and other mills, quicksilver should or should not be fed inside the mill, according to the result. If the mercury is not badly floured, it would probably be good practice to add the quicksilver inside the mills, but if it results in heavy loss due to flouring, all amalgamating should be done on the outside plates.

AT many copper mines the water from the workings is conducted through long series of boxes filled with scrap tin and old iron junk, on which the metallic copper in the water precipitates. Some abandoned copper mines from which the water flows yield enough copper in this way to make it an object to owners to provide the sluices and scrap iron for its collection. The cement-copper is dried, sacked and shipped to smelters. It usually runs about 60% copper.

A TANK connected with a mill to supply water to batteries or concentrating machinery must be provided with a device to control the inflow of water, in order that the head may be constant. This may be done by providing a cock on the inlet pipe, actuated by a float. As the water lowers the float opens the valve; as the tank fills the valve automatically shuts off the inflow, and the water is thereby maintained at the nearly constant head so essential in satisfactory concentration.

WHERE mining claims have been properly located, and in later years the monuments have disappeared, the owner may replace the old with new monuments, conforming to the original description. A new location is unnecessary. No matter how carefully the owner may survey the claims, or cause them to be surveyed, the United States Deputy Mineral Surveyor must also survey the claims prior to patent, except in the case of placers on surveyed government land, where the claims must conform to the legal subdivisions of the land. Two or more responsible persons, fully acquainted with the facts, may act as witnesses.

IN the case of a mining claim being located May 10, 1902, and no assessment work being done during 1903, the claim reverts to the public domain at midnight December 31, 1903. Any legal proceedings in 1905 looking to foreclosure of a mortgage given on the property in 1902 or 1903 would be of no moment. If the claim were not properly 'represented' as required by law, it reverts to the government and C. had a right to re-locate the claim as against A. B. and the Sheriff. If a claim holder could escape performing assessment work by mortgaging his claim there would be thousands of claims covered by mortgage, real or otherwise, and no assessment work need be done by those thus willing to evade the law. The assessment work must be done, even after application has been made for patent up to the time the money is received by the land office and receipt issued therefor.

SULPHURIC ACID is not suitable for flocculating pulp, in the operation of the cyanide process, and as far as known to 'Concentrates,' alum is not used for this purpose, though it is known to have a clarifying effect on solutions carrying slime. At Dale, Cal., the conditions are peculiar and lime is undoubtedly the best material to use for clearing solutions. About eight miles south of the hills in which the O. K. and other mines of the Dale district are situated, limestone occurs which could be used in making lime; also, at the mouth of the San Gorgonia Pass, near Whitewater station. Wood is also available at the latter place, and it might be advisable, for commercial reasons, to burn lime at Whitewater and haul to Dale. Possibly there may be other occurrences of limestone nearer to Dale than those mentioned. Thus far lime is the best precipitant known for settling slime, and the cheapest.

THE cost of obtaining a mining patent is difficult to arrive at arbitrarily, for the reason that the cost of the several items which make up the whole are not all definitely fixed by law. Under ordinary circumstances, $300 should cover the entire expense of patenting a single quartz claim of 20 acres, and about $250 for patent to a single 20-acre placer claim. The following are about the costs: United States Land Office fee, $10; office of Surveyor-General, $35, for stationery and office work, or $40 if a placer. An abstract of title must be supplied by the applicant, and the cost of this varies greatly, anywhere from $10 to $100 or more, according to circumstances. The cost of publication is not fixed, nor is the attorney's fees, and these also may vary greatly. The United States Land Office in California gives the following figures as being approximately the cost of patenting a quartz claim: Payment on land, 20 acres, at $5 per acre, $100; Surveyor-General—deposit, $35; publication notice, $25; affidavits, etc., $5; deputy surveyor, $40; Land Office fee, $10. Total, $220. To this add the attorneys' fees, abstract of title and incidental expense. The cost of a placer patent is about the same for a 20-acre claim.

THE territorial law of Arizona requires in locating a mining claim the following acts: From the time of locating of a mining claim the locator shall be allowed ninety days within which to do, or cause to be done, the following things: To cause to be recorded in the office of the county recorder of the county in which the claim is situated a copy of the location notice; to sink a discovery shaft in the claim to a depth of at least 10 ft. from the lowest part of the rim of the shaft at the surface, and deeper if necessary, until there is disclosed in said shaft mineral in place; to monument the claim on the ground so that its boundaries can be readily traced. The failure to do all these things, here enumerated, in the time and space specified, shall be construed an abandonment of the claim, and all right and claim thereto of the discoverer and locator shall be forfeited. Thus it is seen that the Arizona law is specific, and provides a penalty for neglect to perform any or all of the requirements of the territorial statute relating to the location of mining claims. As the law has never been passed upon by the Supreme Court of the United States, there is a possibility that a locator who had done the necessary work of development, but who had failed to stake and record the claim, might be able to retain his title to the claim. The courts have decided, however, that the States and territories have the right to enact additional legislation as to mines that is not in conflict with the Federal statutes.

FURMAN gives the following as an excellent method of assaying gold and silver in copper mattes, pig copper, and in ores carrying a high percentage of copper: One A. T. of material is introduced into a No. 5 beaker and 100 cc. of distilled water are added, stirring the mass with a glass rod; 50 cc. of nitric acid (sp. gr. 1.42) are added, and the solution is allowed to stand until the action of the acid has apparently ceased. Then 50 cc. more acid is added, and the solution is allowed to stand in a warm place until the red fumes are driven off; the solution is now diluted with distilled water to 500 cc. and allowed to stand for several hours. The solution is now filtered off through a rather heavy 4½-in. filter-paper, the water used in transferring the precipitate to the filter being usually sufficient to remove the copper and silver salts. To the clear solution normal sodium-chloride solution (1 cc. = 10 mgms. silver) is now added in slight excess. A large excess is to be avoided, as silver chloride is soluble in an excess of salt. The solution is stirred and 10 cc. of a saturated solution of lead acetate are added, with stirring of the solution. Then 2 cc. of sulphuric acid (one part acid to one part water) are added, and, after stirring, the solution is allowed to stand for a few hours. When the precipitate has settled the solution is filtered off and the precipitate is washed into the filter, finally washing the precipitate to remove copper salts. The filtrate should be perfectly clear. The filters are removed from the funnels, and, after wrapping them around the precipitates, are placed in 2½-in. scorifiers and dried by placing the scorifiers on a hot plate. When dry the papers are burned by placing the scorifiers in front of the muffle, the scorifiers finally being pushed back into the muffle to destroy all the carbon and sulphur. To scorifier, containing the gold residue and the silver-lead precipitate, is added 5 gm. of litharge, 15 to 20 gm. of test-lead and 1 gm. of borax glass. The charges are now scorified at a moderate temperature, and when the scorifications are finished are poured. The lead buttons, which should weigh from 6 to 8 gm. each, are cupelled so as to show feather litharge, and the gold-silver buttons are weighed. The buttons are then flattened and parted for gold in the usual manner. The assay is usually run in duplicate, and the two results should agree almost exactly. This method may also be used to advantage for the determination of gold and silver in base ores, as gray copper, arsenical sulphides, etc. The method may also be used for the assay of silver sulphides.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

THE BEST SHAPE FOR A SHAFT.

The Editor:

Sir—The subject of the best shape for a shaft, which Mr. Burrows brought up in the MINING AND SCIENTIFIC PRESS of Feb. 24, seems to have been settled by American miners; for the use of the long, rectangular form is almost universal in our country. There are but few departures from this practice, the four-compartment square Red Jacket shaft of the Calumet & Hecla being the most notable in recent times. The Forman shaft on the Comstock was made in L form, three compartments being arranged in a long rectangle (about 5 by 4½ and 4½ and 6 ft. clear spaces) with a 6 by 7 ft. clear, pump-compartment across one end. That disposition was not a success in the constantly moving ground of the Comstock. There is no solid brace for the end of one long wall-plate which bears against the middle of a long plate in the pump-compartment. This is inherently an insecure installation, and the long, narrow form is probably the best for ground that is not so exceptionally firm as that of the Lake Superior trap rocks.

Mr. Burrows has encountered a situation that many another engineer working in Mexico will have to meet. He describes the rock as being extremely firm, as indeed it must be, if an old shaft, 320 ft. deep, is still "in almost perfect condition." Timbering in such a case may be reduced to a framework sufficient to carry the guides and pump-columns, but that in itself is no light duty in a shaft 2,300 ft. deep, which is to have an output of 1,000 tons per day. The mere form of the shaft cannot affect the size of the timbers used, which will be determined by the weights and speed of hoisting. The depth of shaft and output given mean considerable weights moved slowly or lighter weights with high speed, and either one requires strong framing. On account of the interest of this case, I trust that a friendly discussion will not be objected to.

First, I will remark that there is no question here of an L shaft except in the old part, and there the plate running across the center could be braced well enough. The proposal of the directors to cut out the entire end would utilize the whole of the present shaft, but the manager's proposal would utilize only 50 or 63% of the old shaft, according to the use or non-use of wall-plates. The manager proposes to sink a 5 by 16 ft. shaft below the existing 10 by 10 ft. shaft, but that would not give two 5 by 4 ft. compartments in the old shaft, even without wall-plates. One of them would be 4 by 4 ft. 8. in. without a wall-plate in the new part, and 4 by 4 ft. 4 in. with one. Of course the full size can be had by making the addition 7 ft. long instead of six feet.

The effort to reduce costs by cutting out some of the timbers, the wall-plates, does not seem practicable. The timbering of a shaft is composed of units that are dependent upon each other, and are knit together by the bracing against the walls. Every thrust upon a timber is met by a counter-brace on the other side. Especially must the timbers that carry the guides be well braced and also supported by posts. Otherwise they are likely to be torn out by the swiftly passing cage. This is particularly true when the timbers are so light as eight inches. I have known five sets to be demolished at one stroke. For this reason I doubt if any system of timbering which omits wall-plates can be considered trustworthy in a shaft of the depth and output given in this case. At 800 ft. per minute it will take six minutes for a round trip, or 20 trips an hour for two compartments, and for 20 hours hoisting the live load will be 2½ tons. This allowance leaves only four hours for errands, timbers, etc.; which is too little. This load and this speed cannot be maintained unless the timbering is very good. In the stable ground of this mine 8-in. sticks may answer, but they must be framed in the best manner.

These considerations lead me to prefer the directors' plan of enlargement by cutting out the whole width of the shaft, but the pump-compartment must have a cross-brace in line with the dividers in the hoist-ways. As the greatest width that can be obtained, with full timbering, in a 10-ft. shaft, is four feet for two clear spaces, I think that the length of each space should not be less than five feet, and the directors' plan will require a shaft of 17 ft. 8 in. length.

If it is considered that a system of 4½ or 5-ton skips will serve the mine adequately, the directors' plan might be reduced to four compartments, two 4 by 5 ft. hoists and two 4 by 6 pumps, in a shaft 13 ft. long.

It is evident that the question of timbering is the most important of those brought up, except, perhaps, the limitation of a shaft for such heavy work to three compartments. Undoubtedly 8 by 8 in. timbers are small for a shaft 10 ft. wide, however long, but it is hardly possible to put in 10-in. timbers, for they would leave open spaces only 3 ft. 9 in. wide, and the guides would come out of the narrow dimension.

The mines in the district from which Mr. Burrows writes are likely to be supplied liberally with water, and I consider that roomy pump-compartments are a necessity.

It is hard to bring Mexican ways into line with American ideas. A native friend of mine down there is sinking a shaft five feet square on a very important mine. He already has 100 gal. water per minute, merely as an earnest of greater favors to come.

New York, March 7. JOHN A. CHURCH.

THE BEST SHAPE FOR A SHAFT.

The Editor:

Sir — I have read with interest Mr. Burrows' article which appeared recently under the above title. I believe that there is still something to be said on both sides of the controversy, and that some conditions not mentioned in the article should be taken into account before final decision is rendered.

Regarding the manager's proposal, I agree that the required capacity (1,000 tons per 24 hours) can be attained through two hoisting-compartments 4 by 5 ft. each from a mine whose total depth is 2,300 ft. By no means all of the ore at any time will come from the lowest level, and with six or eight-ton skips and loading-pockets at mine stations, 1,000 tons can easily be hoisted in two 8-hour working shifts. It would be necessary to handle timbers, if passed down these compartments, and possibly also men outside of these 8-hour shifts. If much timbering is necessary in the workings above 320 ft., it would be advantageous to install a special hoist for operating a timber cage in one corner of the old Mexican shaft not occupied by rock hoisting. In case the manager's proposal is adopted, I would modify it by making the 5 by 16-ft. cross-section continuous to the surface, which would mean cutting out the old Mexican shaft in the left-hand lower part (as shown in the illustration) for a depth of 320 ft. from the surface. This arrangement would allow of a man and timber hoist of limited size to be operated in the pump-compartment even though that compartment be partly occupied by steam, air and water lines, etc., and these pipes could be handled directly through their own compartment. This would, however, make the pump-compartment rather crowded and the pipe-lines would necessarily be huddled together on one side, making them inaccessible for repairs. If the shaft be made a couple of feet larger, this difficulty will, in a measure, be remedied. The shaft would then be 5 by 18 ft. instead of 5 by 16 ft., as the manager suggests. This timber-hoist arrangement in the pump-compartment is in successful use in this district in shafts 1,000 ft. and more in depth.

The question of a separate timber-hoist has been omitted from Mr. Burrows' discussion. He also fails to state the rock-handling appliances to be used in the shaft. These are important points in the determination of shaft-capacity. With a special timber-hoist as outlined above, the main hoist-ways can be used for handling rock exclusively, and the skips or cages need never be used in working hours by timbermen, bosses or miners — at any rate after the men are down for each shift.

Mr. Burrows does not mention the present or projected existence of neighboring shafts. An adjacent shaft in the same property would modify the conditions governing the shape and size of the shaft under discussion. He implies that there will be only one shaft in the mine.

The question of timbering is not worked out in any detail by Mr. Burrows in comparing the two "proposals." He states that very little timber is necessary except dividers. If this is the case, the dividers would not necessarily be larger in the cross-sections in the square than in the narrow shaft. The length per set with end-plates and without side-plates in the narrow shaft for a three-compartment arrangement, would be 20 ft.; the dividers for the large shaft (10 by 10 ft.) would be also 20 ft. per set. If end-plates are added in the large shaft, the length of timbers per set without wall-plates, would be increased to 40 ft.— twice that required in the small shaft.

It is obvious that with equal hoisting-area, that is, 100 sq. ft. in either case, the narrow shaft would consist of four compartments and would take, neglecting thickness of timbers, 65 ft. in all, linear, for a complete set of wall-plates, side-plates, and dividers; while the square or 10 by 10-ft. shaft would only take 60 ft. linear, for a complete set. It would be interesting to figure in detail the above timber considerations which I have sketched roughly.

I regard the pump and ladder-way as shown in the directors' proposal much larger than necessary, and think that it would be desirable in case of continuing the shaft 10 by 10 ft. size, to run both dividers clear across, as assumed in my discussion of timber above, thus making the shaft four-compartment instead of three-compartment. This arrangement would provide nicely for timber-hoist and man-way, too.

I can see no reason for ever enlarging the 10 by 10 shaft to a 10 by 16 size unless it is desired to greatly increase the tonnage over that stated. For a shaft of large capacity, 4 by 4½ ft., or thereabouts, is the smallest allowable size for a single compartment in which either a cage or a skip may be operated. In case three compartments of approximately equal size fulfil the requirements, a long and narrow shaft allows of this arrangement with less cross-sectional area than if the shaft were square, for in the latter case, the shaft, for practical working reasons and for strength of timbering, would properly be divided into four compartments. Of course, the square shaft, 10 by 10 ft., will have more space for breaking the ground, as is stated in Mr. Burrows' article, and it could be broken with deeper holes, but possibly the ground may be such that the 5 by 16-ft. shaft will break well enough, and the cross-section being 80 sq. ft. as against 100 in the square shaft, will make a great difference in the amount of 'muck' to be handled.

I would differ a little with Mr. Burrows' statement that "buckets will be filled and waiting" after a depth of 300 ft. is passed. He apparently assumes that in sinking, hoisting is done from the bottom of the shaft directly to the surface. It is, however, especially in sinking the lower lifts, more advantageous to bulkhead the shaft near the bottom and remove the dirt by an auxiliary hoist placed in the mine, using buckets from the bottom to this bulkhead level. Then the buckets are emptied into mine-cars and the cars are hoisted at the cager's convenience, perhaps after he has finished his hoisting from upper levels; or the shaft dirt can be directly dumped into skip-loading pockets above the bulkhead. By this well-known method of using a bulkhead in sinking, the distance for hoisting waste from the shaft is greatly lessened, and there are other advantages too well-known to require mention.

Mr. Burrows concludes with an appeal to the authority of eminent engineers where work has been done in other regions. I believe that local conditions so influence this shaft question that unless the local conditions in two places are first found similar, argument from authority is of little avail.

ALEXANDER FORSYTH.

Victor, Colorado, March 9, 1906.

AIR-HAMMER DRILLS.

The Editor:

Sir — In the experience meeting on air-hammer rock-drills, we rise to say a few words for this great saver. One of the first of the Hardsocg machines was used at the Melones mines after we had spent considerable time and money on one of our own, and our first impression of it was outlined in a letter to a friend, in March, 1904.

"Replying to your inquiry concerning the improved boulder air-drill: It is made by the Hardsocg Wonder Drill Company at Ottumwa, Iowa, in the corn fields. It is called the Little Wonder, and it is. In our rock it will drill to a depth of two feet as quickly as a 2½-in. common air-drill mounted on a tripod. The steel is ⅞ in. and the bit we use is 1¼-in. diam. The drill weighs 19 lb. The first one they sent us was made of cast steel, the handle being cast solid on the shell. The handle broke off by the jar in a very few minutes. We tied an old piece of rubber hose on for a handle and have been using it ever since, when we needed it to drill boulders in the stopes or at the chutes. They made for us one of forged steel, the handle forged on. This one has not broken. The secret of its superiority lies in its simplicity, which is made possible by not introducing a ratchet and rotating mechanism, which puts too much light material in action. In this drill an equivalent result is accomplished by using more air, and exhausting the air through a hole in the center of the bit, or drill-steel, which delivers the air at the bottom of the hole, instantly following every stroke; this blows out the cuttings, and jumps the bit slightly back from the bottom of the hole. We have drilled 45 ft. with it in five hours actual running; drilling holes from 6 to 18 in. deep. We have not yet tried it on a hole deeper than two feet. Of course, as the hole deepens, the drill loses efficiency, relative to an ordinary drill. The bit we are using is round, with six cutting edges, radiating from the center. This obviates the danger of a fitchered hole, or a three-cornered hole. The cutting edges are so close together that if the bit struck several times in the same place, it would break off the edges of rock between the cutting edges, and the hammer strikes so fast, doing its work by a great number of light blows, instead of a few heavy ones, that there is very little danger of a fitchered hole. The shank of the drill is hexagonal, and is loose in the chuck. The whole machine is swiveled by the runner, by a slight twist of the wrist, which tends to give the same result as mechanical rotation, as the bit is twisted with the machine, and the blows are so rapid that a half hundred are struck while a slow man is turning the machine half around.

"It happens to fit our conditions exactly for 'bull-dozing' or block-holing. It has the same effect on the runner as a galvanic battery, and ought to be good for rheumatism."

After trying one of the drills our friend wrote us that while the drill might be good for rheumatism there was some danger of its inducing St. Vitus dance! We might add that after Mr. Hardsocg and Mr. Shaw and others have divided, by the callipers, the discovery of this little drill for mining purposes, they may find, covered with dust in the attic, that a similar machine was in use 15 years ago in mines in

Germany, known as the Franke drill, weighing only 16 lb. and striking 6,000 blows per minute.

FRANK LANGFORD.

Melones, Cal., March 6, 1906.

BLAST FURNACE *vs.* REVERBERATORY.

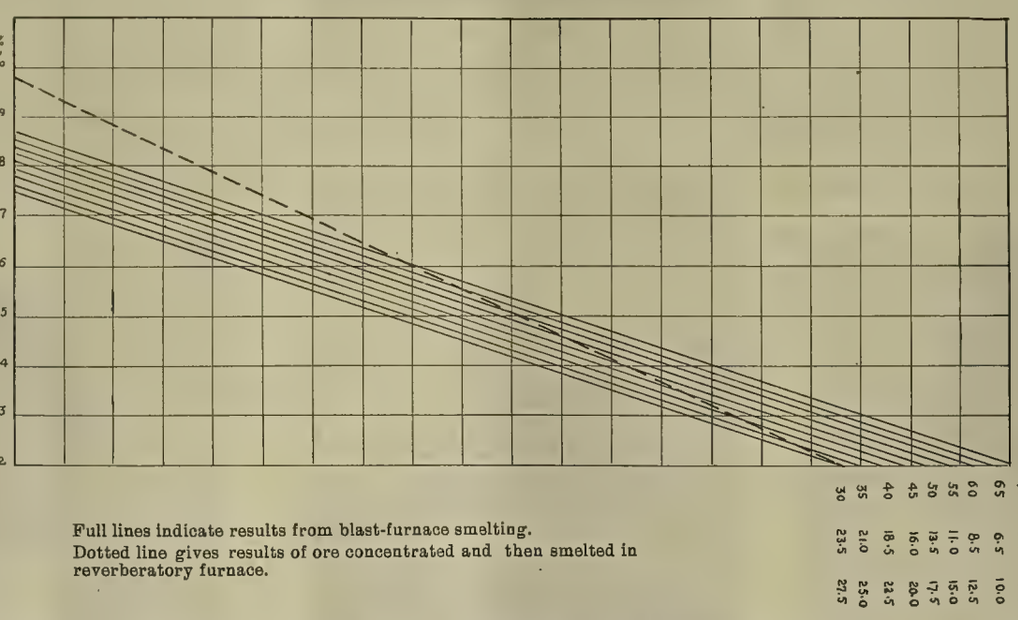
The Editor:

Sir—Referring to the questions on this subject, outlined by your correspondent, Mr. James W. Neill, I beg to offer the following:

(No. 1) *On what should the choice of furnace type be principally based? Character of the ore, fuel, fluxes, building materials?*

The choice of the furnace type should be based on (1st) the character of the ore to be treated, in its values in copper, silver and gold, and its analysis for silica, iron, lime, sulphur and alumina, particular attention being given to the amount of pyrite in the ore, which can be utilized as fuel; (2nd) fuel—the cost and character of the various fuels obtainable in the vicinity—for example, coal or oil for reverberatories and coke for blast furnaces; (3rd) the cost of fluxes, including the cost of iron ore or limerock delivered at the plant; (4th) building materials—cost of silica and fire-brick, the labor of bricklayers as compared with the labor of iron workers, and the cost of iron work; (5th) losses in slags—the loss in blast-furnace slags to be compared with the loss in tailing at a concentrator added to the loss in reverberatory slag, it being assumed that there will be no loss in roasting if the proper chambers are constructed to recover the flue-dust.

Attached is a chart showing the net values, with the product sold in New York, of an average silicious ore of the Butte district. This ore runs from 30 to 70% silica; 3.5% iron calculated as oxide to 23% iron as oxide; 7 5% sulphur to 27.5% sulphur and from 2 to 10% copper, with corresponding values in silver and gold. The full lines are the net values of blast-smelted ore; the dotted line is the net value of the reverberatory-smelted ore. All costs and metal losses in the different processes are taken into consideration. The chart shows the best method of treating such ore. The 30% silica and 2% copper ore can be treated equally well by either method. A 5.1% copper ore should be concentrated when the percentage of silica is 60 or over.



Full lines indicate results from blast-furnace smelting.
Dotted line gives results of ore concentrated and then smelted in reverberatory furnace.

(No. 2) *What are the comparative costs per ton of daily capacity of each type of furnace? In the case of the reverberatory, this cost should include the expense of the necessary roasting plant.*

I think to the roasting plant should be added water concentration.

The cost of treating an ore in a blast furnace varies with the analysis of the ore treated; let us take, for comparison, an ore of the following analysis: Copper, 5%; silica, 70%; metallic iron, 9.6%; sulphur, 11.7%; the cost of making a matte from this ore, per ton of ore treated, will be in the following ratios:

Reverberatory smelting	1
Blast-furnace smelting	2.66

while the net value of the product from the same ore, sold in New York, would be

Reverberatory	1
Blast furnace	0.9

A reduction of the silica and an increase of the iron and sulphur in the ore would reduce the cost at the blast furnace, but would not make much change in reverberatory costs.

(No. 3) *What is the comparative space requirement for an equal tonnage?*

Omitting the space for storage-bins, shops, offices, etc., the blast-smelting method requires 40% of the space necessary for reverberatory smelting, with its necessary adjuncts, concentrating and roasting. The storage-bin space would depend entirely upon the amount of material the proprietor felt it necessary to keep in stock to provide against shortages due to failure of transportation facilities, etc.

(No. 4) *What is the comparative cost of mechanical equipment for equal tonnages?*

The cost of a mechanical equipment for a blast-furnace system is about 96% of that necessary for a reverberatory system. Under the heading of blast furnaces, we include power, blast furnaces, converter lining, converting and casting furnaces. Under the heading of reverberatory smelting, we include power, concentrating, mechanical roasting, reverberatory smelting, converter lining, converters and casting furnaces. The local tramming or cost of transfer of material between departments is not taken into consideration, as the relative position of the buildings and method of transportation will determine these factors.

(No. 5) *What are the comparative costs of power, labor, fuel, and repairs?*

Comparative costs for an equal tonnage, bringing the material from ore up to matte, are about as follows in this vicinity:

Power—reverberatory smelting, 50% of blast-furnace smelting. Operating labor—reverberatory smelting, 66% of blast method. Fuel—reverberatory smelting, 12% of blast method. Repairs, labor and material—reverberatory smelting, 167% of blast method.

(No. 6) *What are the comparative amounts of capital tied up in furnaces of each type, and how does this affect the cost per ton of daily capacity or of output?*

Locked-up values in metals—reverberatory smelting, 136% of blast smelting. Plant investment—reverberatory smelting, 123%. Total reverberatory smelting, 124% of blast smelting.

The locked-up values affect the cost per ton of output only to the extent of the interest on the money tied up. The plant investment affects the costs to the extent of the interest on the money tied up and the depreciation of the plant.

(No. 7) *What are the limiting necessities in the way of fuels for each type?*

For blast furnaces, coke should not run to exceed 25% ash, with corresponding fixed carbon, and should develop not less than 10,000 British thermal units.

For reverberatories of modern construction, coal with long flame is necessary, and this should develop at least 10,000 B. T. U. Oil is not available in this locality at present, and is not considered.

(No. 8) *What are the comparative losses in slag, dust or middle products?*

The loss in slag by blast furnace on ores of the Butte district will be a little higher than the corresponding loss by reverberatory furnaces, on account of the large amount of barren flux added to the ore to form a blast-furnace charge. This excess loss in slag, however, is more than counterbalanced by the loss in tailing by water concentration.

There should be little or no loss in middle products, if proper dust-chambers are provided, by either method.

(No. 9) *What are the defining limits of each type in regard to slag composition?*

For the ores of the Butte district I find that the economical limit of blast-furnace slag is reached when the lime is 33%, the average slag produced from the Butte ores being 40% silica, 23% iron oxide, 26% lime.

The reverberatory slags we do not care to run above 5% in lime. The average reverberatory slag here runs 38% silica, 43% iron oxide, 2.5% lime.

(No. 10) *How do these differences in slags figure out in financial margins per ton smelted?*

All the silica and iron in the slag produced in the Butte district is supplied from the ores themselves; all the lime must be purchased; limerock, however, is very cheap in this vicinity.

(No. 11) *What method of charging do you advocate for a copper furnace (assuming the atmosphere to be oxidizing)?*

I advocate mechanical charging by means of side-dumping cars for blast furnaces; reverberatory furnaces are preferably charged from hoppers set above the roof of the furnaces, to discharge through the furnace-roof, near the fire-box end.

(No. 12) *Would you bind, in some manner, all fine for use in the blast furnace? Incidentally, what are the difficulties of treating fine ore in the blast furnace?*

All fine for the blast furnace should be bound in some manner before charged; if slime is available, briquettes can be made cheaply and charged while still moist. This is the usual custom here. These briquettes usually consist of a mixture of slime, fine ore, a little fine concentrate to add fuel, and, in addition, whatever fine coke is recovered from the ashes of the reverberatory furnaces.

The difficulty with fine ore in blast-furnace smelting is mainly in the formation of crusts on the sides, together with the production of excessive quantities of flue-dust, which has to be re-handled. The fine ore also greatly reduces the output of the furnace; it is important to have as little mixture of fine and coarse in the charge as possible. The reverberatory is the proper place for the fine, unless no flux material is available at a reasonable price, also in a finely divided form.

In this district, on account of variation in the ore, the combination of reverberatory and blast-furnace practice has proved to be the most economical. This has given us abundant opportunity to study the relative merits of each system, and the notes given above indicate the results obtained in actual practice here.

E. P. MATHEWSON.

Anaconda, Montana, February 28, 1906.

AIR-HAMMER ROCK-DRILLS.

The Editor:

Sir—Having read the article by Mr. Edward A. Rix, which appeared in your issue of February 24, entitled 'Air-Hammer Rock-Drills,' I venture to believe that the readers of the MINING AND SCIENTIFIC PRESS will be interested to know the results of a study on rock-drills operating upon the air-hammer principle, but designed for heavy work.

Mr. Rix in his article treats mostly of small plug drillers and believes that they will take an active part in the mining of the future. I believe that just as these drills bid fair to be used entirely for light work, that rock-drills constructed upon similar principles will displace the heavy reciprocating drills for heavy work.

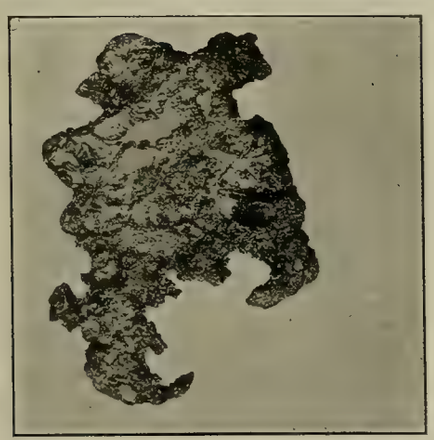
There are two drills, operating on the pneumatic-hammer principle, now on the market which have been designed to compete with heavy air-drills, that is those using a cylinder of from 3 to 3½ in. diam., and it is the merits of these two machines which I wish to discuss. One is the water-Leyner drill, which is operated by compressed air, and the other is the Box electric drill, operated by electricity. The analogy to the pneumatic hammer is more marked in the case of the compressed-air drill than with the electric drill, however; since, in the latter, the hammer is moved by the action of an enveloping reciprocating cylinder. The hammer is therefore drawn backward, due to the formation of a partial vacuum between it and the rear cylinder-head; upon the return stroke the rapid downward movement of the enveloping cylinder hurls the hammer against the end of the drill-steel with great force; the hammer in this case weighing 10 lb., acting through a stroke of four inches and striking 600 blows per minute.

We now come to the reasons for constructing rock-drills on the pneumatic-hammer principle. In the first place, it should be remembered that in this type alone is water successfully forced to the bottom of the hole. This is an important advantage, as it permits of washing away the crushed rock and allows a stream of cold water to play continually on the cutting edges of the drill-bit, thus preserving its temper and increasing its life. In the case of the reciprocating type of rock-drill there are no means of continually forcing water to the bottom of the hole; the drill-bit has, therefore, to be moved up and down through a heavy formation of mud, thus greatly retarding its speed and acting as a cushion for the blow, since all this mud has to be expelled from between the drill-bit and the bottom of the hole before the cutting edges can come in contact with the rock. Furthermore, the constant rubbing of the drill-bit against

the side of the hole wears away the gauge of the cutting edges rapidly. With the hammer-drill, on the contrary, the drill-bit always remains at the bottom of the hole, except for a slight rebound, and the gauge is consequently preserved for a longer period; the holes are more perfect and a marked saving is effected in the cost of sharpening the drill-steel. Furthermore, the constant reciprocation of the drill-steel in a hole filled with mud means that a large amount of power is used up in overcoming friction and in lifting the heavy drill-steel before each blow. As the hole becomes deeper, the weight to be lifted becomes greater and the friction is increased.

This tends to retard the speed of the drill and, as a matter of fact, a drill operating in a hole 15 or 20 ft. deep will seldom run more than two-thirds as fast as it would in a hole only four or five feet deep. This, in my opinion, explains the fact that the pneumatic-hammer type of drill will operate just as effectively as the reciprocating type for deep holes. The bit is always resting on the bottom; the forcing of water under considerable pressure, to the bottom of the hole, continually washes away the crushed rock which might tend to cushion the blow. Futhermore, there is no slowing up in the action of the drill when depths of 15 to 20 ft. are reached. This probably equalizes the slight loss due to part of the energy of the blow being dissipated in the form of heat or used up in compressing the end of the drill-steel, the greater part of the blow being transmitted the length of the steel due to the well-known power of resilience of metals. It might also be remembered that this type of drill strikes at least twice as many blows per minute as the reciprocating type and that this lead increases with the depth of the hole.

A special factor operating in favor of the Box electric drill is its ability to drill a straight hole and not be deflected from its course by seams or pockets. Deflection of the drill-bit causes it to stick or 'fitcher,' as the miners say, and leads to endless delay and trouble. It is particularly noticeable in



Native Copper as It Occurs in the Ore.

drilling through seams running in a line diagonal to the axis of the drill-hole. When the Box drill encounters such a condition, the drill-bit action is such that the cutting edges rebound but a small distance from the bottom of the hole and, being supported by a water-tube to within about three inches of the cutting edges, any sticking or 'fitchering' is prevented; even under the worst conditions but a slight deflection is produced. It is even possible to drill one hole at a very slight angle across another, giving but a slight deflection in the second hole.

And now a word in regard to the power required. It must be apparent to everyone who reads this article that the new type of drill can use but a small fraction of the power required to operate the reciprocating type. Furthermore, the amount of power always remains the same irrespective of the depth of the hole, since there are no heavy drill-steels to be lifted at each stroke and no friction to overcome except the friction in the drill itself. This permits of a reduction in the number of models which have to be manufactured, and which the user has to buy in order to have the proper sized drills for different classes of work. The size of the drill is governed more by the diameter of the hole, than by its depth. The manufacturers of the electric drill put out only two sizes, one for drilling small holes for stoping and 'plug' and 'feather' work, and the other to correspond with an air-drill with a three-inch piston.

It will be seen, therefore, that the new type of drill possesses advantages which the reciprocating type can never possess, owing to radical differences in design and breadth of application.

New York, March 6, 1906. W. R. HULBERT.

THE present annual diamond yield is between 400,000 and 600,000 carats, valued at about $30,000,000 to $50,000,000. The returns from the four De Beers mines are valued at about $25,000,000 yearly. The combined output of the diamond fields of Australia, Brazil, and British Guiana are insignificant in comparison with the South African yield.

Copper Mining on Lake Superior.

Written for the MINING AND SCIENTIFIC PRESS by J. PARKE CHANNING.

To one who has not visited the Lake Superior copper mines for several years, the two most notable things are the developments on the Baltic and Kearsarge lodes. On the Baltic lode, the Champion, Trimountain and the Baltic are each turning out about 2,000 tons of ore per day, or very nearly 2,000,000

Trimountain Mill.

tons per annum for the group. To the north of the Baltic, explorations are being conducted on that lode at the Atlantic, the Superior, and the Isle Royale mines, each by its own company, while at the

Tamarack No. 3 Shaft.
The Deepest Metal Mine in the World.

south end, the Copper Range Company, which controls the Champion, Trimountain and Baltic, has taken an option on Sections 1 and 2, T. 53 N., R. 35 W, this being part of the old Globe property

Champion Mine.

Here the Baltic lode was found some years ago by a diamond drill, and a shaft is now being sunk on the hanging-wall side. The drill-holes showed that the covering of drift was approximately 200 ft. deep with considerable water. To get through this 200 ft. of water-bearing drift is no easy matter, the first attempt by driving lathe behind steel sets being unsuccessful. Time was an object and so a timber drop-shaft was decided upon. This is now down about 117 ft., and progress has been satisfactory. The drop-shaft is made of Oregon timber 16 in. square, the outside dimensions being 16 ft. by 26 ft. The lowest side of timber has been chamfered so as to produce a cutting edge which has been protected by straps of iron. The water is being handled with one No. 9 pump, though a second one is held in reserve, and there seems no reason why a successful landing of the crib on the lode should not be made before the winter is over. This work is in charge of Mr. F. W. Denton, who is the manager of the Copper Range mines. He is now engaged in introducing the filling system in both the Champion and Trimountain mines, this being the same method of mining which has been so successful at the Baltic. It has been frequently described and consists of breaking all of the lode, no matter how wide, sorting it by hand, sending up about 60% of the material broken, and leaving the remaining 40% to act as filling. The backs or floors between the levels are taken out on a caving system somewhat similar to that used in the Kimberley diamond mines.

An extremely interesting experiment on a large scale is being carried out at the Champion mill on the shore of Lake Superior; it is an experiment which is likely to revolutionize the treatment of Lake Superior amygdaloid ore at least, and perhaps even that of conglomerate. The usual method of treating Lake Superior rock is to crush it at the mines to about a 6-in. size and then send it to the stamp-mill, where it is reduced by steam-stamps having a capacity of from 500 to 700 tons of ore per day, the material being discharged through a screen with ⅜-in. apertures. The coarse copper is taken out by an intermittent discharge at the bottom of the mortar, another portion of the coarse copper passes into the launder leading from the stamp, the balance of the material being screened. The oversize from the screen is jigged, the tailing thrown away and the middling re-ground and passed on with the under-size from the screen, which is then treated in the usual way with hydraulic classifiers, jigs, perhaps a second re-grinding, and a final finishing on Wilfley tables. In the experimental section of the Champion mill, the material as it comes from the mine is passed over a long screen, wetted down with water, and the feeder as usual picks out the coarse copper. Instead of going to a steam-stamp, however, it goes into a crusher and is brought down to about two-inch size. It then goes through a series of jigs, rolls and trommels which it is hardly necessary to describe, as the exact machines and their proper proportion have not been thoroughly decided upon. The screening, however, is carried down to one-quarter inch, after which any finer sizing is done with the old-fashioned hydraulic classifiers. Re-grinding is effected in a Huntington mill and the last fine material is passed over Wilfley tables. The steam-stamp, or in fact stamps of any kind, are, of course, entirely eliminated. In material carrying such small amounts of copper as the Lake Superior ore, the average assay-value of the amygdaloid being probably not over 1 5% copper, it is extremely difficult to make comparative tests and absolutely impossible to sample the original material. The relative efficiency of different methods can only be determined by sampling different tailings and even this is difficult. There is no doubt, however, that, in another three months, comparative figures will be available, which I hope Mr. Denton will communicate to the profession. In the meantime, inspection of the mill-unit in operation will convince the most skeptical that the method is a decided improvement upon the steam-stamps. One has but to look at two specimens, such as are shown in the accompanying illustrations, to realize that the rounded piece taken from a steam-stamp mortar was, in all probability, originally much of the same shape as its companion, which was taken from one of the coarse jigs. What has become of the angular parts? Undoubtedly they have been broken off and a large portion of them converted into slime of varying size. One has but to look at the Wilfley tables in that part of the mill using rolls and observe a narrow ribbon of cop-

Native Copper After Passing Under the Steam-Stamp.

per, say half an inch wide, and then go over to the stamp-section of the mill and see on the corresponding table a belt of copper from three inches to five inches wide, to realize the difference in the production of fine copper. So far everything indicates that the rolls section, new as it is and probably unbalanced, produces as good a saving as the stamp section, and of greater importance is the demonstration that the coal consumption per ton of rock is only one-half that of the stamp section. The space occupied is almost identical; in other words, the mill addition of four bays will accommodate two steam-stamps, each with a capacity of 600 tons of rock per day, or four roll sections, each treating at least 300 tons of rock per day. No figures of water consumption are yet available, but there is no reason why this should not be materially reduced over the stamping practice. It is admitted that for years and years the Lake Superior stamp-mills used altogether too much water. L. D. Ricketts has said of Arizona, that the very shortage of water in that arid country has been the cause of perfecting its concentrating methods.

At the Calumet & Hecla mill the water consumption has probably been reduced to the lowest of any plant on Lake Superior; it is one-half of what it was five years ago. There is some doubt expressed as to whether a roll-and-crusher treatment would be of great advantage on ore like the Calumet conglomerate, because of the intimate manner in which the copper is distributed through the rock and its extreme fineness. In fact, it may be said that it is impossible to crush Calumet conglomerate so as to free all of the contained copper, or as it is popularly expressed, in order to get copper out of the conglomerate it becomes necessary to slime it.

The exponents of the steam-stamp have not been idle, and the success of the Nordberg steeple-compound stamp at the Osceola mill is most pronounced. The old stamps were 20 by 24 in. and with steam at 110-lb. gauge pressure stamped 500 tons of rock per head per day. The new stamps are 15 and 24 by 32 in., and with steam at 150-lb. gauge pressure each head crushes 700 tons, an increase of 40% with the same coal consumption per head, or to express it in the terms usually used on the Lake, the tons of rock per ton of coal have been increased 40%. In the construction, the low-pressure cylinder is placed above the high pressure so as to facilitate the removal of pistons. The low-pressure cylinder is single-acting, its lower side being kept in constant communication with the condenser, no steam being admitted to the lower side. On the up stroke, when but little power is required, boiler steam is admitted to the lower side of the high-pressure cylinder, the upper side exhausting to the receiver and the upper side of the low-pressure cylinder as well as the lower side being in contact with the condenser. On the down stroke, when all the power is required, the upper side of the high-pressure cylinder is supplied with boiler steam, the lower side discharges into the receiver, and the upper side of the large low-pressure cylinder is supplied with steam from the receiver. This gives a very effective blow and accounts for the increase in capacity of the stamp, while using the same size of mortar and shoe. Diagrammatically, the strokes are as shown in the accompanying sketch.

On the Kearsarge lode, the Calumet & Hecla have two shafts at work. The Centennial, which for years endeavored to work its poor conglomerate and then tried to find a mine on the Osceola amygdaloid, has now two shafts on the Kearsarge, both of which are showing well. Next comes the South Kearsarge, belonging to the Osceola, then the Wolverine and then the North Kearsarge, also owned by the Osceola Company. Next beyond, the Allouez has sunk a shaft and encountered the Kearsarge amygdaloid, and after years of fruitless work on its conglomerate, will no doubt now be a paying proposition. Next comes the Ahmeek with two shafts, its surface plant now nearly reaching completion. Next the Mohawk, a well established property, is turning out a regular product and both north of the Mohawk and south of the Calumet & Hecla, the continuation of this wonderful persistent and productive Kearsarge amygdaloid is being traced.

Tamarack No. 3 shaft is now the deepest shaft in the world, being 5,128 ft. deep, and it is at this mine that some of the problems, which eventually will come up on the Rand, will be solved. The increase of temperature at Calumet is about 1° F. for every 225 ft. of descent, the normal temperature 50 ft. below surface being about 50° F. The above rate of increase would not make the bottom of the Tamarack much over 75° F. The temperature, however, in these workings, and also in the lowest workings of the Calumet & Hecla, probably is considerably higher than this, because of the heat evolved from the respiration of the men and the burning candles, while the humidity of the air makes it particularly uncomfortable to bear and to a large extent limits the efficiency of the miners. The problem of ventilation at these great depths, is yet to be solved. At present, nothing but natural ventilation is used, though in time great fans will unquestionably have to be installed, probably both plenum and exhaust at

Underground in the Champion.

the respective downcast and upcast shafts. Another question to be decided is whether to continue the vertical shafts down indefinitely and drive the cross-

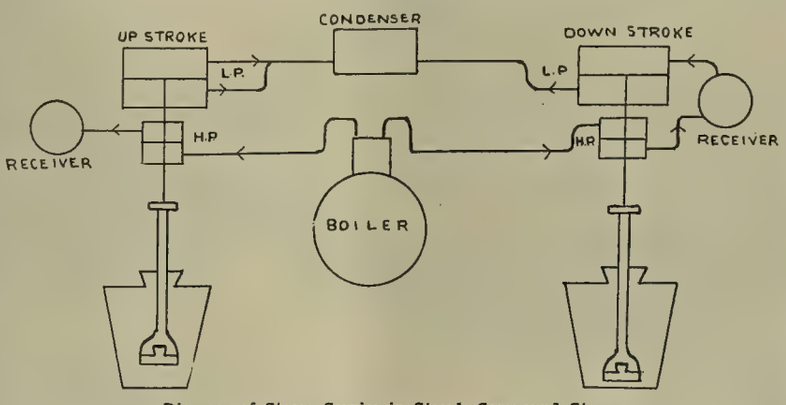


Diagram of Steam Service in Steeple-Compound Stamp.

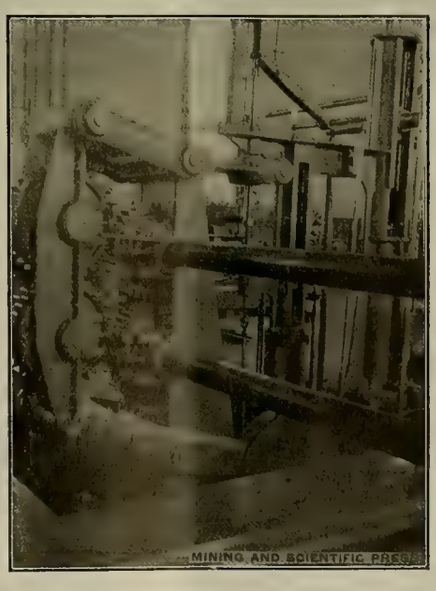
cuts, which are getting longer and longer. This is a great hardship, as the conglomerate dips at an angle of 37°. The consensus of opinion among engi-



Reversing Gear of Nordberg Hoist.

neers is that slopes should be driven from the bottom of these shafts far enough back from the footwall of the conglomerate to make them safe, and that the hoisting should be done in two stages, one stage being the slope and the other the vertical shaft. The Calumet & Hecla are using this method in one place and are driving a slope due north under what is known as the Five Forties. As this slope is about half-way between the dip and the strike, it is of course very much flatter than anything which would be undertaken at the Tamarack.

The question of timbering, at both the Tamarack and the Calumet & Hecla, is also one of great importance on account of the rapidly increasing cost of timber. Experiments are being made with cast-iron columns and there is no doubt that some modification of the filling method, as used by Mr. Denton at the Baltic, will be tried at one or both of these mines. The conditions on the Calumet conglomerate are, however, exceptional, inasmuch as the first layers of the hanging-wall trap are extremely loose and blocky, and fall with the slightest provocation. Exactly how this loose ground is to be handled is a serious question yet to be solved. The Tamarack has already made a material saving in timber by driving its drifts to the boundary, where the stoping is begun, gradually retreating toward the crosscut. The slices are, however, taken one above the other so that by the time the floor of the level above is reached, a great deal of timber on the lower part of the stope needs strengthening. It is possible that a more close following of the 'long wall' retreating system, as is used in the North of England coal mines, might possibly be carried out in this work. No matter what method is followed, care must be taken to keep the proper air current in the face, and it seems quite probable that the study of coal mine conditions would aid in solving the problem of mining this comparatively narrow conglomerate at such great depths. Unquestionably the pioneer engineering work of deep mining has been done at the Calumet & Hecla and at the Tamarack, and that same spirit which has solved problems in the past can without doubt be trusted to solve them in the future. Upon Mr. James McNaughton at the Calumet & Hecla, and Mr. William J. Uren at the Tamarack, has the task devolved.

Conservation of Natural Wealth.—Marl or bog-lime beds which have been used as the base for cement factories have been produced in the past few thousand years, but the lake algæ and shells are still busy abstracting lime from the hard water. One thing which it would be interesting to know is how fast our marl beds are growing and how many acres of pond or bog and cubic yards of bog-lime a company would have to have so that when they got around they could begin over again. The State might well encourage such an investigation and also see how fast it could be accumulated by the fittest plants. In the same way with peat bogs. If peat comes to be a popular fuel, it will at first be mainly on accumulated peat that we shall draw; but it will also be worth while to know how fast a bog can be made to grow, and whether its growth can be stimulated by changes in water level or by encouraging appropriate plants. It is a good reason that scientific research be endowed on just this ground, that when the present coal mines are exhausted one may know where most readily to find new, and when these in turn are but hollow voids some inventor shall have found a storage battery that will turn Ariel from a tricksy sprite to a mighty genius of work and make the windmill as much a source of power as the water-wheel. Thus as earlier sources of power, lumber waste and coal are exhausted, one may turn to oil or gas, or use water power to develop electric heat or grow fuel either as four-foot wood or as peat, whichever shall be proved by scientific experiment to be the most economical. A Frenchman has recently suggested setting a coal mine on fire and pumping down just enough air to make water gas and then burning this gas as it comes to the surface. If this idea proves feasible it will add untold millions to the wealth of this State in seams which it will not now pay to burn. But in any case by the time our coal is gone we should be ready with our streams already dammed and copper cables covering the land to furnish more power from water than we now use from coal.—A. C. Lane in *Popular Science Monthly.*

One of the most extensive fields of onyx marble in Mexico lies along the border between the States of Durango and Coahuila. Beds of this marble have been found in the hummocks at the foot of the mountains which fall within the jurisdiction of the Hacienda Jimulco and on both sides of the Aguanaval river. The most important of these marble beds lies west of the Mexican Central Railway, being 20 km. from Peralta, at the foot of the high sierra on the way to Cuencame. The beds east of the railway lie in a similar position in the hills at the bottom of deep valleys. Some are in the Viboras ravine, while others are near Paso de Calvo ranch, 4 or 5 km. from Noria station. The proximity of the railway, the quantity and beauty of the marble, unite two facilities for making these beds of easy exploitation. They are not only extensive, but are important because of their accessibility. With few exceptions the quality of the Jimulco onyx is good from the surface.—*Mexican Herald.*

Destruction of Camp Bird Mill.

The daily press contains confused accounts of a big snowslide at the famous Camp Bird mill, 5½ miles from Ouray, Colorado. We have authoritative information that the snowslide carried away 50 stamps and 35 vanners, together with the covering of the entire 70-stamp mill.

But as if this were not bad enough, a fire broke out in the surviving part of the mill and in the absence of water, due to the destruction of the pipe-line, this was consumed, so that the whole 70-stamp mill and its accessories were destroyed. At least six months, and probably more, will be required to re-build the mill and resume production.

The Camp Bird mine is in Imogene basin, one of those semi-circular valleys frequently seen among the mountains of southwestern Colorado. The mine itself is at an altitude of 11,200 ft., or 1,840 ft. higher than the mill, with which it is connected by an aerial tramway 8,550 ft. long. The first accounts spoke of injury to the bunk-house at the mine, to the angle-station of the tramway, as well as the mill. If this be a fact, it is apparent that a series of slides must have occurred, but we are informed that the bunk-house was not seriously injured.

The bunk-house was built by Mr. Thomas F. Walsh, the former owner, and was one of the best in the country; Mr. Walsh always pursued the wise and humane policy of taking good care of his men. The tramway cost $55,094 and was an excellent example of this branch of engineering, while the mill, originally built in 1898, has undergone repeated addition and improvement since the transfer of the property to the English company, in 1902.

The Camp Bird is one of the great mines of America, and has done much to increase the reputation of Colorado as a profitable mining region. The following figures are eloquent:

Year ending April 30.....	Gross earnings.	Profit at the mine	Expended on construction account.....	Net value ore developed	Dividends paid.	Per cent.....
	$	$	$	$	£	
1903.....	1,976,289.68	1,293,007.42	77,438.88	3,113,604	164,000	20
1904.....	1,923,911.74	1,217,783.56	153,584.75	1,649,433	164,000	20

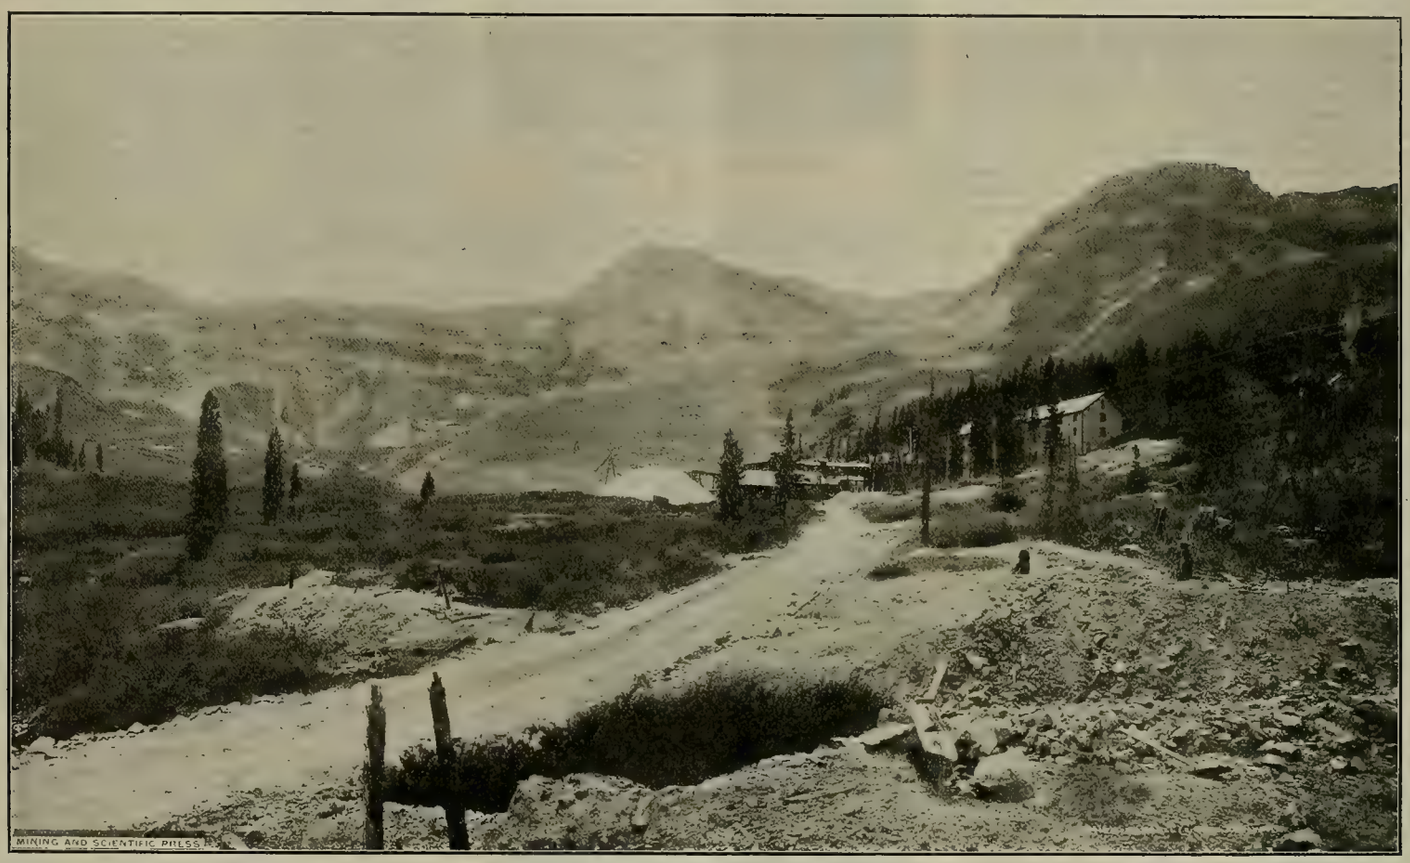
It was stated by Mr. John Hays Hammond, in the company's last annual report, that the reserves in the form of ore already broken would yield a profit of $2,600,000, while the ore blocked out showed an estimated net profit of $2,250,000. These two sums are nearly equal to the capital of the company.

The accompanying illustration shows the bunk-house and the tramway, together with the entrance to the upper mine workings. Owing to foreshortening, the mountains do not look as steep as they really are. Over the range to the right is Savage basin, where are the Tomboy and Japan mines, tributary to Telluride. Over the ridge at the back of the picture is the cañon that leads to Ouray, and on the further side of that cañon are the Yankee Girl, Guston and other celebrated mines.

The destructiveness of a snowslide must be seen to be appreciated; if at a distance, one hears the roar of its onset before the eye has caught sight of the cloud of snow that marks its fierce career; if near-by, all attempt to observe is abandoned in the effort to escape. But few persons have been caught in a snowslide and yet lived to relate their experience. The snow comes down like a torrent; if it is a 'ground' slide it uproots trees and carries rocks with it; if it is due to the descent of a new snow-fall on an older surface, it is less violent, but deadly enough. Men have been found dead whose heads and shoulders only were pinned under the snow, which congeals instantly into a solid mass; such slides are often mere masses of slush, heavy and wet. The dry snow gives a man a chance, for it carries air with it and permits him to battle for escape. The writer narrowly missed such a death when overwhelmed in a comparatively small slide at Riverside, between Ouray and Red Mountain. This spot—Riverside—was the scene each year of successive slides, and occasionally they would accumulate a mass of snow more than a hundred feet thick. This would not melt during the warm season, and one summer the four-horse coaches used to pass through a tunnel cut through the unmelted snows of the past winter. To a big slide, buildings and tramways are as the twigs that are snapped by a hurricane. On the heels of the descending avalanche there comes a whirlwind due to the vacuum caused by the rapid motion of the snow-mass and this cyclonic disturbance in the wake of the slide is frequently the cause of as much loss of life as the burial in the snow itself.



No. 1 and No. 2 Tunnels. No. 3 Tunnel, Tramway Terminal and Bunk-house.

The Camp Bird Mine, Colorado.

THE Lodon *Statist* publishes a remarkable table of last year's wages and expenses for white, Kaffir, and Chinese labor in the South African gold mines. The Rand output in 1905 is assumed as worth £20,802,074. It is then concluded that, as near as can be gauged, the £20,000,000 output may be split up as follows:

White wages: 25% of production	£5,000,000
Kaffir wages and food: 12½% of production	2,500,000
Chinese wages: 40,000 coolies at £2 per month, 5% of production, say	1,000,000
Stores (adjusted to producing mines): 27½% of production	5,500,000
Profits tax	425,000
Managerial expenses, head office, claim licenses, etc. (by difference)	575,000
Dividends earned and paid	5,000,000

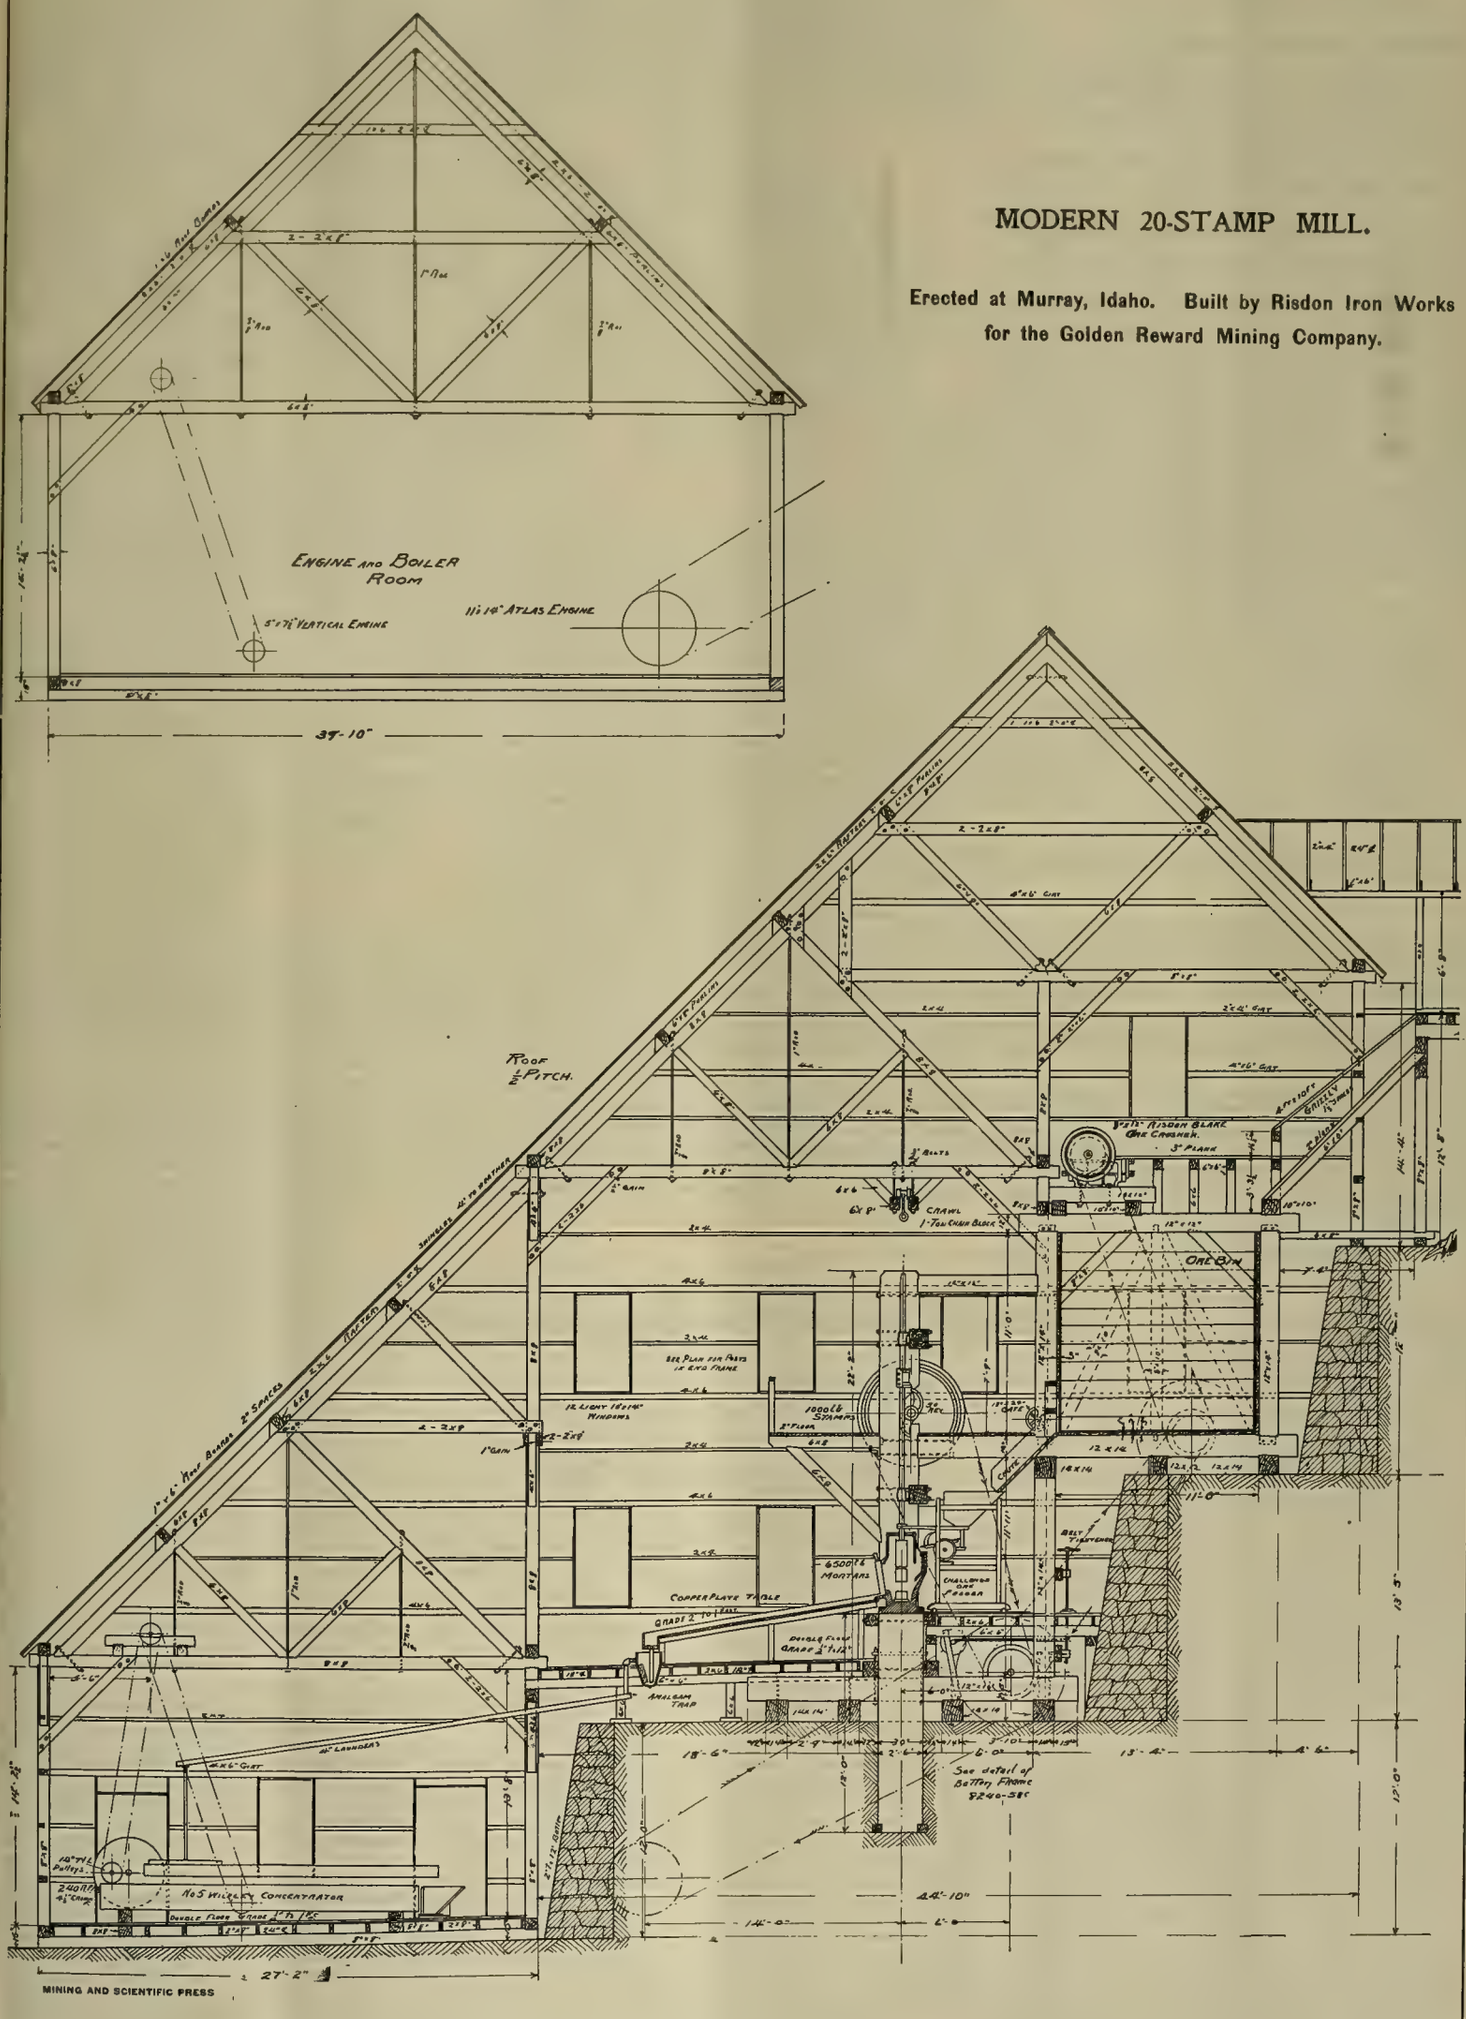
A Modern Stamp-Mill.

There is still a variety of ideas among mining men as to what constitutes the best type of construction for a stamp-mill. The designers of mills in their years of experience have gained a great deal of valuable information relative to effective construction, but it is true that they do not always embody in their mills that which they know from experience to be the best. The reason for this is that not infrequently the customer has some ideas of his own concerning the arrangement of the mill; these he wishes to be applied, whether they conform to the recommendations of the constructor or not. The result does not always redound to the credit of the man or the firm whose name is attached to the machinery. Occasionally the miner gives *carte blanche* to the builder, so that he can design after his own ideas, and the result is then likely to be a modern mill, of sensible and practical design. Such has been the result in the mill herewith illustrated. It was designed by T. R. Brooks, of the Risdon Iron Works, of San Francisco, for the Golden Reward Mining Company, of Murray, Idaho. The side elevation shows that the building is constructed so as to meet the heavy snowfall not unusual in that region, as indicated by the steep pitch of the roof and the ample bracing of the interior. Ore is delivered at the top of the mill upon a grizzly, the oversize going to the breaker sheet, and from there to the bins beneath. From the bins the ore passes automatically through the several stages of treatment until it reaches the tailing dump. Steam power is employed, the engine driving the line-shaft by means of two belts, running on two band-wheels attached to the crank-shaft of the engine. These are calculated to give a slightly higher efficiency and to make running more steady. There are separate engines for the concentrators and for the dynamo which supplies light for the premises. The arrangement of battery, the mortar-blocks and the sills are worth studying, for, although advancing nothing particularly new in mill construction, they are along practical lines, and an improvement on many we have seen elsewhere.

A BEARING METAL should have, according to R. C. Carpenter, a considerable adhesion to a lubricant and be readily wet by it; should be softer than the shaft, so that it will be injured instead of the shaft in case of grit in the bearing or a failure to maintain lubrication; should be hard enough to keep its shape under any loads that are likely to come on it; should have a melting temperature less than that of the journal, and should not adhere to the shaft when melted. For ordinary purposes, Prof. Carpenter recommends babbitt metal, but for more severe conditions he advises a mixture of 50% of aluminum, 25% of zinc and 25% of tin.

MODERN 20-STAMP MILL.

Erected at Murray, Idaho. Built by Risdon Iron Works for the Golden Reward Mining Company.



Mining and Milling at Ymir.

Written for the MINING AND SCIENTIFIC PRESS by D'ARCY WEATHERBE.

The town of Ymir is, by rail, about 15 miles south of the city of Nelson, British Columbia, and the Ymir mine is five miles, by wagon road, from the town. It is situated on the north fork of Wild Horse creek, near the junction, at an elevation of 5,000 ft. The scenery is wild and rugged, and in winter particularly picturesque, though the timber on the steep slopes of the Wild Horse ravine has been at some previous date destroyed by fire, so that only the dead and blackened stumps and logs of a once mighty forest remain. The formation in the neighborhood of the mine is assigned by the Canadian Geological Survey to the Nisconlith series of the Lower Cambrian, and the rocks consist of quartzites, altered argillites, and other slaty rocks. The stratification is distinct near the mine; the strike is northerly and southerly; the dip is generally at an angle of 60° northwest. Although the vein is persistent, the ore-body takes the form of a lens, which, at the crop, is 500 ft. long and 40 ft. at the widest part; it has a strike north 70° east and a dip of about 70° northwest. The vein-filling is quartz, containing gold and silver, the sulphides of lead and zinc, and calcite. A little iron and copper pyrite is also seen occasionally in the faces; the pyrite in larger quantities was characteristic of bonanza patches. Within the limits given, the ore varies so much at different points that

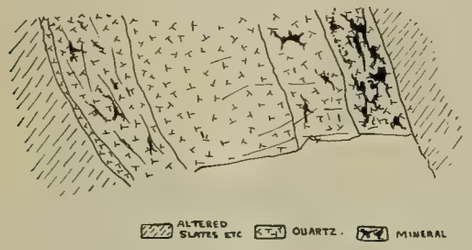


Fig. 2.

it is difficult to average the width. It has a distinctly banded structure and contains streaks and inclusions of country rock; it also displays clear evidence of secondary deposition. A good example of this action is seen at a point on the No. 10, or 1,000-ft., level, as explained by the accompanying sketch (Fig. 1). Here the main portion of the vein is a dull bluish white quartz. On the hanging wall is a streak of milky white quartz three inches wide and with a distinct slaty parting on both sides. Between this band and the first-mentioned quartz is an eight-inch width of interlacing stringers of the same character of milky quartz that lies on the hanging wall, enclosing angular inclusions of quartzite, but, what is most interesting, the stringers from this band extend toward the foot-wall *through the main portion of the vein*, and are evidently of later origin. The whole width of the vein at this point is 14 to 15 ft. Such evidence of banding, etc., may be found at other points in the mine, particularly at No. 7 level (Fig. 2), and it is generally found that the mineralization follows only certain bands. Dioritic dikes occur throughout the mine and in most cases appear to have a strong influence on the enrichment, those portions of the vein in the vicinity of the dike generally giving richer ore than elsewhere. As a rule, these dikes pass from one wall into the other, intersecting the vein, but not disturbing it physically. I noticed two exceptions to this rule, however, on the 1,000-ft. level (See Fig. 3). At a point about 115 ft. east of the entrance crosscut on this level, a dike may be observed in the hanging wall, and on meeting it, the vein appears to turn and follow it for a few feet before pinching out. It cannot be found on the foot-wall side and, so far as I observed, it does not intersect or disturb the vein in any way. All of these dikes cut the strata in strike and are generally vertically inclined. On the other hand, at the western end of this same level, a dike occurs interbedded and dipping with the strata and underlain by a quartz vein. It naturally crosses the vein obliquely, as does the bedding of the rock, and appears to cut it off abruptly. At the time of my visit, a crosscut on the under side of the dike was in progress to prove the foot-wall of the vein.

The mine was originally opened on top of the hill by a 'glory hole' 450 ft. long and ranging from 20 to 40 ft. in width. Shafts were then sunk and levels driven consecutively until a depth of 700 ft. from surface had been gained. At this depth the ore appeared to become poor. From a point in the hillside, 1,000 ft. below the crop, a crosscut over 2,000 ft. long was driven through the barren country rock to the vein, and the No. 10 or 1,000-ft. level was driven 800 ft. east of the crosscut and 345 ft. west, at which point the dike previously mentioned is encountered. The winze from the 700-ft. level was continued down the intervening 300 ft. to meet the 1,000-ft. level, but

Fig. 1.

with this exception the block between the 700-ft. level and the 1,000-ft. level is unexplored, though a raise is now being made through this ground.

The pay-ore has been stoped to a large extent above the 700-ft. level, the overhand method being used entirely, and the winze to the 1,000-ft. level is utilized as a chute, all the ore being trammed through the crosscut at the bottom. The widest portions of the vein itself do not necessarily all carry value, and great portions of it, consisting of 'bull quartz,' are left in the mine at many points. The mineral chiefly denoting value to the eye is galena, and as this contrasts with the white quartz so as to be readily seen, no system of sampling and assaying is employed. The ore is, to a large extent, free milling, an extraction of 77% of the gold and 44% of the silver being made in the mill. The mill-building is equipped with 80 stamps, but at present it is partly dismantled; 25 stamps are kept running, and of the 24 Frue vanners, 10 are in use. The stamps weigh 850 lb. and No. 9 and 11 slot screens are used in the mortars. From 2½ to 3 tons per stamp are crushed. The boiler-plant includes three 60-h.p. Robb-Mumford internally fired boilers and one return-tubular boiler of the same capacity. The engine-room contains one 200 h.p. Goldie & McCulloch engine, one 4-drill Rand compressor, one 10-drill Ingersoll compressor, and a dynamo for the electric lighting. A small water-power is available, but in winter it is only good for 15 stamps. The concentrate is shipped to the smelter and the tailing from the mill is carried by sluice to the cyanide-plant on Wild Horse creek. To prevent extreme wear, the sluices are arranged with drop-boxes, as in Fig. 4; they have riffles on the bottom. The plant and process have been fully described by Mr. E. C. Holden,* and with a few modifications they remain the same. The pulp from sluices is passed through two conical separators, which collect 73% of sand, 27% flowing away as slime. The slime is of slightly lower grade than the sand. Six steel tanks, each with a capacity of 210 tons, are used for leaching, the cycle being six days when running at full capacity. Centrifugal distributors placed over the center of each vat feed the pulp uniformly. When the mill is running at full capacity this takes about 30 hours.

Instead of the dry lime previously fed to the vats to counteract acidity, milk of lime is now used. The weak solution is then admitted (0.1% KCy), and then the strong solution (0.2% KCy). The pulp is then washed and the vats are discharged by hose and nozzle, the jet being under a pressure of 160 lb. per sq. in. The tailing is sampled by a water-wheel device and then by separators cutting out one part in sixty-four. Solutions pass from solution tanks to leaching vats and out to sump, from where they are pumped back to tanks and brought up to strength. The zinc used for precipitation is cut on the premises and the mud is cleaned up about once per month. It is roasted in pans to volatilize the zinc, as well as the white precipitate which forms, and is then treated by sulphuric acid to drive off the zinc remaining. From here it is placed in the filter-press to eliminate moisture, and the resultant cakes are smelted in the usual manner with flux to produce the bullion. The tailing is said to contain from 60c. to $1 when received at the plant, and the cost of production is given at 52c. by the Provincial Geologist of British Columbia, made up as follows:

COST OF TREATMENT PER TON.

Cyanide at 22c. per lb.	$0.200
Zinc at 9c. per lb.	0.020
Lime at 0.009c. per lb.	0.001
Fuel at $2.50 per cord.	0.019
Clean-up supplies.	0.029
Repairs	0.014
Miscellaneous	0.003
Labor (wages $3.50 and $4.50 per day)	0.234
Total	$0.520

Three men are employed besides the superintendent of the plant. The production at this mine from 1900 to 1904 is given by the same authority as follows:

1900—42,660 tons, yielding $7.20 gold and 1.06 oz. silver per ton.

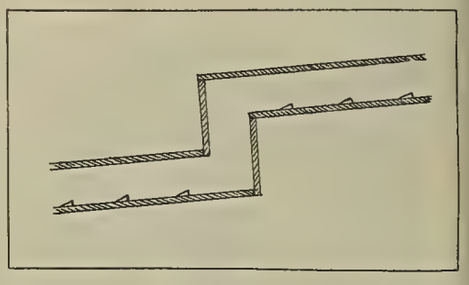

Fig. 4.

1902—About 50,000 tons, yielding $6.69 gold and $1.27 in silver.

1903—Some 54,000 tons, yielding 11,160 oz. gold, 5,060 oz. silver and 515 tons lead, with a total value of $300,000. In 1904 the output was not so great, being between 30,000 and 35,000 tons.

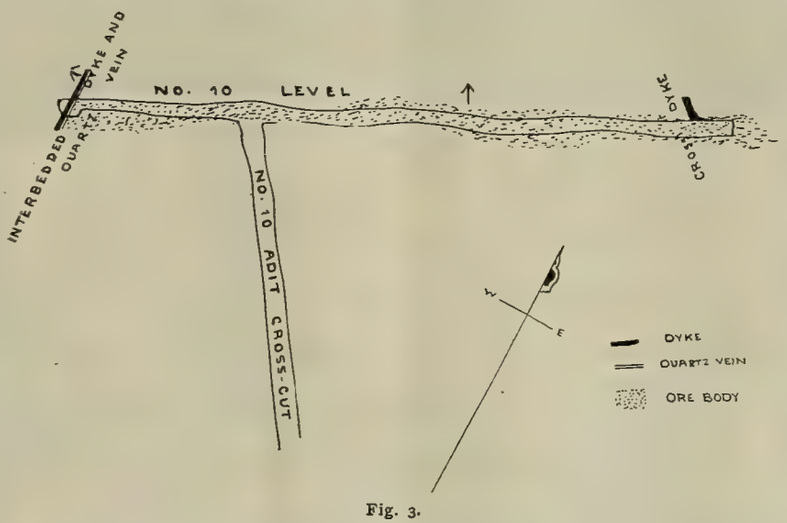

Fig. 3.

Transactions Amer. Inst. Min. Eng., Vol. XXXIV, pp. 599 to 608.

THERE is a well-known difficulty in determining the constant of a watt-hour meter connected with a variable line pressure. If the voltage between the mains is so nearly steady that it can be regarded as constant, the testing of a registering watt-hour meter on customer's premises is not a difficult operation. The usual plan, in this country, is for the tester to carry about with him a portable form of rheostat load, and either a standard wattmeter or a voltmeter and an ammeter. The time occupied in making a definite number of revolutions is carefully noted for the meter under test, when the known portable load is applied. A table then shows whether the meter is fast or slow. If, however, the voltage across the mains is very variable, and the range of variation is, say, from 5% above normal to 5% below, then the load on the meter with a constant rheostat in circuit will vary from about 10% above normal to 10% below, and it is difficult to assign the quantity of energy which has passed through the meter, within several per cent.

TUNGSTEN is mined in Arizona, Colorado, South Dakota and California. A vein four feet wide has been recently found near Cripple Creek. The concentrated ore is worth $100 to $250 per ton. The Troy-Manhattan Copper Co., at Troy, Ariz., mine and concentrate wulfenite, lead molybdate; the American Molybdenum Co., at Cooper, Me., has a concentrating plant. The concentrate is worth about $200 per ton. Much prospecting is being done. The output, in 1903, was 795 tons of concentrate. Uranium and vanadium are mined principally in Montrose county, Colorado, 432 tons of crude ore being mined in 1903, which was concentrated to 30 tons, and sold at $5,625. The ore is carnotite, containing only a small amount of uranium. Titanium is manufactured as ferro-titanium by the Willson-Aluminum Co., from titanic ore from Caldwell county, North Carolina. Illmenite and titanic iron are synonymous.

The Trouble at the Walker Mine.

Written for the MINING AND SCIENTIFIC PRESS by an Occasional Contributor.

The Walker mine was opened below the 300-ft. level by John Powers, superintendent, who for upward of three years contended with the problem as best he could. Now, the 600-ft. level was reached after many a weary struggle with inadequate pumps; often handicapped by lack of funds, skilled men and necessary material, he had the satisfaction of installing a powerful compound condensing duplex station pump, apparently adequate for a long time to come. For six months this pump had been within less than 100 miles of the mine, but snow, blizzards, mud and slush had combined to delay its arrival. For three months Powers had worked on, almost to desperation, suffering from a diseased foot that threatened his very life, so that when the new station pump began its leisurely work he laid down his duties and sought relief at the hands of a surgeon in a distant city.

The Walker company was controlled by a board of non-resident directors, which, like most such bodies, was divided against itself. Just prior to the departure of Powers, two of the directors, the minority, visited the mine, taking with them a young mining engineer named McNevin, a protege of theirs, who was duly installed as manager *ad interim*, with the assurance that he should continue in the employ of the company as consulting engineer if his services were satisfactory. McNevin was a graduate and carried a parchment that entitled him to all the respect and deference due to his profession, and, unfortunately for himself and the company, seemed to consider this as qualification enough. The instructions from Powers as to the care of the pump, the provision of 'sand sumps' at stated intervals as the work progressed, and other items pertaining to the general work of the mine, fell on deaf ears. He would sit in the hoist station and entertain himself and the engineers by recounting his accomplishments, and would build himself up in his letters to the company by criticising Powers and holding up his work in an unfavorable light, without a word as to the difficulties under which the work had been done.

As the drifting and crosscutting progressed there was an increase of water, necessitating higher speed for the pump. The pump took water from practically an open sump, at the intersection of the main crosscut and the first drift west. In making the turn from the drift to the crosscut a 'turn-sheet' was used. One day a car of fine dirt upset into the sump. Mac damned the old superintendent for the event and told everybody how *he* would have arranged things. In another day or two another carload of waste went in, resulting in more bad language and a report to the company voicing his disapproval of Powers' methods. Another day, and the third car followed; and then something happened. The sump was filled so that the end of the suction pipe was covered. By great exertion the dirt was partially cleaned out and the catastrophe of a flooded mine was averted for the time, all of which was duly reported to the company, giving in detail the wonderful energy of the writer and the slackness of the methods of the old superintendent; but still the sump remained open, thus inviting more trouble.

No sand sumps were provided as the work of drifting progressed, so all of the fine sand, due to blasting and an excess of water, was washed in. Faster and faster the pump was speeded to hold the water in check and the consumption of fuel increased in exact ratio. McNevin figured the capacity of the pump, multiplying the combined area of the pistons by the length and number of strokes and the volume of water being raised; it was tremendous, according to the figures, while to the practical eyes of the engineers and miners the stream discharged was not noticeably larger.

In the face of the crosscut the drills struck a flow of water that spouted with considerable force, but the situation being considered critical the holes were not fired, but were plugged with wood to keep back the water.

To the suggestion of the pumpman that the valves be examined Mac would not listen, but turned his attention to adding to his pumping capacity. The shaft was already equipped with a No. 9 sinker and a new No. 7 was borrowed from a neighboring mine and installed alongside. To make proper water connections, a line of 4-in. pipe was coupled and gradually let down the shaft as each section was screwed on. When about 200 ft. long, the great weight caused the single clamp that secured the sustaining cable to slip, and the whole line shot down to the bottom, some 200 ft. below. The new, borrowed No. 7 pump was hopelessly ruined and the No. 9 pipe-connection broken. No damage was done to the main steam-pipe but what a few moments would have repaired; but the golden moment passed in wild excitement. The water was rising rapidly, and then the qualities of the real leader developed in McNevin. He ordered the No. 9 pump raised to the 400-ft. level. Another pump, to replace the broken one, was secured and installed. From neighboring mines pipe was borrowed to replace that which was lost and damaged. To the office of the company came the report that the accident was caused by the breaking of the cable; that it was an old one which ought to have been thrown into the pit years before, and that he had now secured a new cable by borrowing, and had thrown out the old one; that had he not have taken prompt action the mine would have been flooded to the top; he had saved it at the 400-ft. level, and now, after ten days of awful hard work, the water was again being lowered. He paid a glowing tribute to the heroic work done by all hands, etc.

A telegram asking him who was in charge, and who was responsible for the accident, was promptly answered by saying "John Powers, superintendent." Finally, after a fortnight of great exertion and an inordinate consumption of fuel, the station pump was again reached and the valves examined, when it was found that both the valves and valve-seats were badly cut. The valves, hard rubber discs, were turned over and the pump again set to work. The excessive firing had over-heated the return arches that were under the boilers, causing the arch supports to warp enough to let some bricks fall out. Again the report scored Powers, as McNevin announced that it was not safe to let the men go into the mine, there being great danger of a fire in the boiler-house that would certainly smother all the men inside; so he had closed the mine and would do nothing except try and keep the water out, unless the board of directors would so order and relieve him of all responsibility, etc.

At this juncture the majority of the board acted, and sent out a thoroughly practical man to investigate, with full authority to act at his discretion. This man, whom we will call Jones, arrived at noon. A brief inspection of the boilers resulted in a call for men, and within a few hours the damage was all repaired, with everything as snug and safe as though all were new. The men were ordered by Jones to report for work on the next shift, and McNevin, after again formally declaring that the mines were not safe, left the camp, vowing dire vengeance, through his 'pull,' for this breach of professional courtesy.

Jones next turned his attention to the station pump, which was working very badly again. The sump was examined and no obstructions were found around the suction valve. A platform around the pump was built at once that effectually protected the sump, so that it would be impossible to fill it again with dirt from the car. The valves were opened and found to be as badly cut as before turning. There were no extra valves, none having ever been provided, so prompt action was needed, for one hour would cover the pump enough to prevent its work. Taking two or three valves and ordering the rest sent up as fast as possible, Jones went outside to devise some means of putting a new face on them, and accomplished this purpose by rubbing them on a red-hot iron until he had burned off enough to form a new, smooth surface. As fast as this was done they were sent in, and when he followed with the last valve all the rest were in place, and in a few moments the pump was started, with water nearly half way up on the low-pressure cylinders. The pump worked better and soon lowered the water.

New valves and valve-seats were ordered, but it was apparent that something must be done to insure safety during the 30 days that would probably elapse before the supplies came. Some sole-leather was secured and discs cut from that. The leather, being soft and thin, would not hold up against the pressure of water, so, to re-enforce them, the hard rubber valves were sawed in two, making each two discs about $\frac{5}{16}$ in. thick. One of these thin discs was placed over each leather, to give it the necessary strength, and the job was done.

The soft leather sucked down into the cut in the valve-seat, making an absolutely tight joint, and the strokes of the pump were reduced from 65 to 28 and the fuel from 10½ cords per day, to simply keep the mine unwatered, to 7½ cords, which not only handled the water, but ran two 3¼-in. machine drills and hoisted from 70 to 80 cars of rock.

The report to the company was a short statement of facts and the assurance that "as long as there were bulls on the range the pump would be kept going, and that it was ample to handle double the present volume of water." It is only to be added that the discredited cable lifted the No. 9 pump and, after being thoroughly inspected, it was replaced on the winch and is good for a long time to come.

This is written, first, as a statement of fact, and, second, to impress on the graduate the necessity of gaining actual experience before trying to build himself up by tearing down others who have come up by hard knocks. The educated young man has a far better chance in the race of life if he begins his active work with a clear conception of his ignorance of homely, practical details, and is alert to learn. For such there is room, and opportunity for abundant success.

THE Lake Superior iron region produced 20,198,311 tons in 1904 as compared to 7,682,548 tons in 1894. The most recently developed range, the Mesabi, took first place in 1895 and has since occupied that position. In 1904 it produced 11,672,405 tons of iron ore.

The Metric System.

The American people have a world-wide reputation for their ingenuity in devices to save time and labor. It is an anomaly that such a progressive people has failed to see the enormous loss of time and labor incurred in the retention of medieval and confusing weights and measures.

Three-fourths of the enormous foreign trade of the United States last year was with countries having the metric system—the system now in use among four hundred and fifty millions of people. Merchants import liquids by the liter, textiles by the meter, foods and drugs by the kilogram, and the innumerable consignments must be calculated into and sold by different measures of volume and of length and by avoirdupois weight and troy weight and apothecaries' weight. In exporting commodities, on the other hand, quantities, weights and measures must be laboriously converted into the terms of the metric countries to which they are shipped.

One may imagine the time and labor lost in these processes and the tendency to prevent the expansion of our commerce that these vexations must exert, for where other things are equal the four hundred and fifty millions of metric potential customers naturally incline to deal with those who speak the same trade language as themselves. The views of exporters and importers show how keenly they feel this handicap and how eager they are for the adoption of the simple, uniform and widely used system which would clear the existing obstructions from the pathway of commerce.

If we had no commercial relations whatever with foreign countries it would seem incongruous that the American people, while progressing in all other directions, should have failed to adopt such a unified and simple system as the metric for the facilitation of internal trade—and this is nearly 20 times as large as that done with other countries. The first step toward adopting the metric system was taken 40 years ago, when Congress passed the law legalizing it in contracts and court pleadings. Six years after that step was taken Germany adopted the metric system—and it has contributed not a little to the industrial and commercial growth at which the world marvels—while we are still weighing copper by one 'standard,' silver by another and drugs by a third, with other confusions 'too numerous to mention' in measures of volume and length.

We have been outstripped in the adoption of the metric system by Japan and by countries that the average American condescendingly regards as half civilized. The metric is taught in our schools, but the children must also learn the complicated systems that are retained in use, although a full year's time would be saved in their education if these were dropped. In electrical operations, in engineering, in pharmacy, in industries that demand nice measurements, like the manufacture of automobiles, and watchmaking, and in numerous other fields the metric system is in common use today. Why longer continue the confusion and the loss of time and labor and accuracy involved in retaining the obsolete weights and measures? Congress should awaken to the fact that this is the twentieth century and comply with the demand for adoption of the metric system.—*The Herald*, New York.

TIMBER PRESERVATIVES.—With the life of telephone and telegraph poles at its present limit, the 800,000 miles of existing lines, requiring 32,000,000 poles, must be renewed approximately four times before trees suitable to take their place can grow. A pole lasts in service about 12 years, on the average, but is made from a tree about 60 years old. In other words, to maintain a continuous supply, five times as many trees must be growing in the forest as there are poles in use. The severity of this drain upon forest resources by the telephone and telegraph companies is obvious enough. Since 1902 the Forest Service has been making a study of the preservative treatment of poles and of the value of the seasoning in relation to treatment. In this work its first object has been to make the timber last as long as possible, so as to check the annual demand for renewal, and thus lessen so far as possible the drain upon the forest. Seasoning was studied in the first place to determine the rate at which poles become air dry; that is, lose as much moisture as they will part with through evaporation in the open air. The time of cutting was also carefully considered. Experiment proved that poles cut in winter dry more regularly than those cut at other seasons, and also show a greater loss in moisture at the end of six months' seasoning. The advantages of winter cutting are, therefore, even drying, with a minimum liability to check, and light weight—an obvious advantage for shipment by freight. Spring or summer cutting secures a more rapid loss of moisture at first, owing to the temperature, but only for three or four months. At the end of from six to eight months spring and summer cut poles are found to have dried only three-quarters as much as winter-cut poles. Spring and summer cutting, however, would result in saving in freight and increased durability if the poles are to be shipped and used within three or four months after cutting.

The Tube-Mill.

The tube-mill consists primarily of a long revolving drum of steel provided with a driving gear for turning it, and with a lining of suitable material to form an inner abrasive surface, and to protect the outer cylinder from wear. The ends of the cylinder are closed by heavily re-inforced cast-iron heads, which have at their centers hollow trunnions through which the material is fed in at one end and discharged at the other.

The lining may be made of silex, a flint-stone quarried in Europe; ironite, a hard, close-grained stone found in this country; porcelain blocks, or chilled iron. At a recent meeting of engineers, W. R. Dowling, of the Robinson Deep mine, said that they had two tube-mills running—one with manganese steel and the other with silex lining. The latter took a larger feed and gave a finer ground product than the former; the pebbles also retained their rounded shape, while with the manganese steel lining flat faces were in evidence, showing a sliding action.

Flint pebbles form the grinders. These are introduced through a manhole at the start, and the supply is replenished from time to time as they become reduced by wear. Grinding is accomplished by keeping the cylinder filled to a little above its axis with ore and pebbles, the whole mass to revolve slowly. The mass tumbles over and over with a wave-like motion, thus utilizing an enormous expanse of grinding surface.

The fineness of the finished product is controlled by the feed to the mill and also, to some extent, by the relative amount of water introduced. Generally speaking, with other conditions unchanged, retarding the feed increases the fineness; and increasing it, reduces the fineness.

Fig. 1 shows clearly where the material to be pulverized is fed into the mill. A flanged connection leading into the trunnion is provided, making it possible to connect the feed-pipe so as to control the feed and at the same time prevent any untidy slopping about of wet tailing. The flow of the material into the mill is with the water, and by gravity, and is intended to be controlled by a valve in the feed-pipe. The trunnion opening at the discharge end, shown in Fig. 2, is left open so that the character of the finished product may be examined at any moment. The end of the trunnion is flanged out and fits into a funnel-shaped guide, which prevents any spilling of the product. Fig. 3 shows the inside of the discharge and with the screen provided to prevent the exit of any coarse particles of the grinding pebbles. The central discharge is one of the latest improvements.

The driving gear can be placed at either end of the mill, as may be desired. The main bearings are provided with large openings for grease-soaked waste. The counter-shaft has collar-oiling, self-oiling bearings. But little time need be lost in replacing worn bearing liners. For the main bearings it is only necessary to jack up the barrel, give a liner a half-turn to the top of the shaft and draw it out. A new liner may then be slipped into place. Liners for the counter-shaft bearings are replaced in a similar manner. The main gear is machine molded.

A mill of 60 in. diam., 22 ft. long, requires about 35 h.p., with 60 to 70% excess momentarily in starting. When Danish flint pebbles are used the consumption will amount to about 100 lb. pebbles per 100 tons of material pulverized. Iron linings last from 7 to 10 months. Silex linings 2½ in. thick last about 60 days.

The capacity will depend upon the conditions under which it is operated. The varying percentage of fine that will be in the product going to the tube-mill will have a distinct bearing on the tonnage that it will handle. For example, in speaking of a product passing a 30-mesh screen, before it is delivered to the tube, there may be 50% of that material which will pass 60-mesh, or there may be only 25% which will pass 60-mesh. This variation in size of the feed naturally will have a corresponding influence on the work which the tube has to do, to make a product of desired fineness. In a majority of cases, it is best to separate the fine from the feed by hydraulic classification before the ore reaches the tube-mill. In some cases it is desirable to classify the product again after it is discharged, returning the over-size to the mill for further reduction. Under such conditions, the mill will handle a larger tonnage; and as the discharge is classified, it insures the return of the over-size for re-grinding.

In one particular instance a 5 by 22-ft. mill, when taking a feed that has passed 30-mesh and reducing it so that about 97% would pass 200-mesh, has handled three tons per hour. In another instance a mill of same size, when taking a feed that has passed a 15-mesh screen, after which it is classified to remove the fine, has handled 12 tons per hour, of which 96% would pass 60-mesh, but in this case the discharge was classified, the coarse material returning to the mill. This variation indicates that the conditions govern the capacity for each particular case. —*Bulletin* No. 1410, Allis-Chalmers Company.

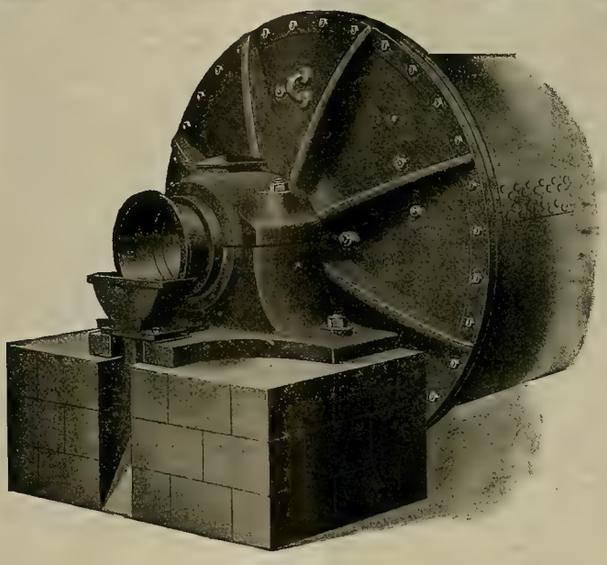

Fig. 2.

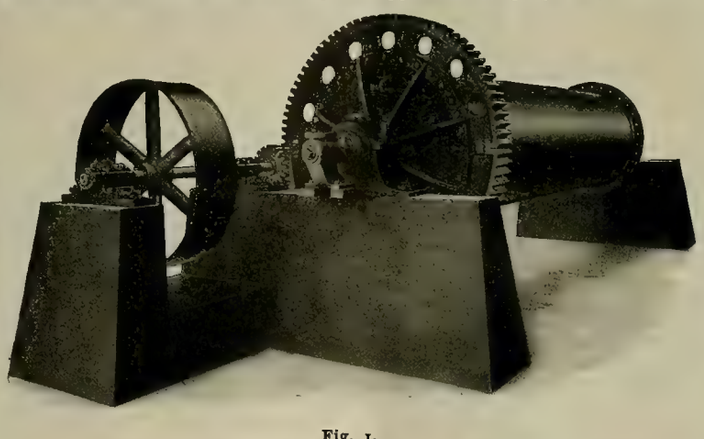

Fig. 1.

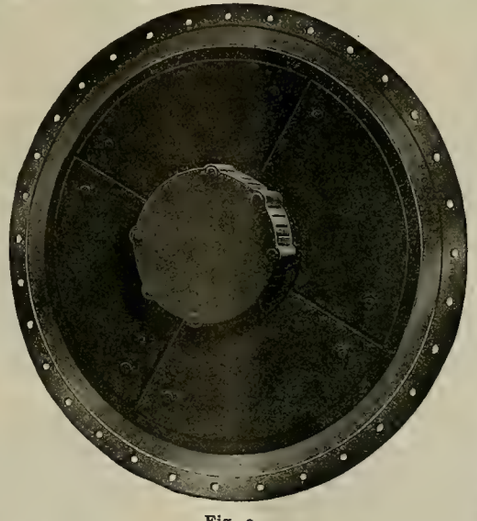

Fig. 3.

THE chief metallic product of Chile is copper, of which, in 1903, 36,600 tons were produced, valued at $7,150,000. The primitive methods employed in mining and reducing the ore greatly lessen its output. With modern machinery and appliances the preparation of the copper for market could be made more profitable. There was also produced 1½ tons of gold, valued at $600,000; silver 42 tons, valued at $425,000; lead, 77 tons, valued at $3,000; manganese, 18,500 tons, valued at $225,000; cobalt, 22 tons, valued at $33,000; iodine, 171 tons, valued at $540,000; borax, 18,350 tons, valued at $790,000; salt, 17,680 tons, valued at $108,000; sulphur, 3,740 tons, valued at $112,000; coal, 898,900 tons, valued at $2,750,000; and nitrate of soda, 1,570,000 tons, valued at $46,700,000. The nitrate product is the greatest source of government revenue.

The Prospector.

Enquiries sent to this department are answered free of charge, submitted by subscribers who are not in arrears The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

The sample marked B. B., from Sonora, Cal., is aplite, a dike granite, with little or no mica.

The black ore from Fish Lake Valley, Nev., is principally magnetic iron. It is probable that this ore overlies a deposit of copper ore.

The rock from Havilah, Cal., marked G. E. T., is a much altered basic dike rock. It consists of decayed feldspathic material and talc scales.

The rocks from Table Rock, Cal., are: No. 7, diorite; No. 8 is a globular form of pyrite (iron sulphide); No. 9 is quartz incrusted with pyrite.

Of the two rocks sent by C. R. from Stockton, Cal., the reddish ore is hornblende granite, the other mica schist, probably due to alteration of a rock similar to No. 1.

The rocks from Tehachapi, Cal., are the following: No. 1, serpentine; No. 2, trachyte; No. 3, chert; No. 4, quartz, colored green, by chlorite; No. 5, rhyolite tuff; No. 6, andesite.

The rocks from Berlin, Wash., are granitoid and contain considerable magnetic iron. The ore is somewhat unusual. The gangue appears to be scales of a silvery white mica.

The rock from Ingot, Cal., is a variety of serpentine. It sometimes carries chrome iron ores, and is often associated with copper ores and gold at contact with other rocks, also with cinnabar.

The bright, shimmering scales on the yellowish-brown, silicious ore from the January mine at Goldfield, Nevada, is margarodite, a silvery hydro-mica, the result of alteration of feldspar, in all probability.

Of the two samples from Helena, Mont., marked C. B., the smaller and lighter piece is felsite, and the larger and darker piece feldspar porphyry. Possibly these two rocks may be found in different parts of the same mass. The sketch indicates that a fault has dislocated the flat vein.

The rocks from Parral, Mexico, marked G. L., are: No. 1, light green, probably a finely consolidated greenstone tuff; No. 2 also greenstone, amygdaloidal, the air vesicles being filled with infiltrated mineral (calcite). No. 3 is a dike rock, apparently a silicified andesite. No. 4 is syenite.

The rocks from Red Rock, Ariz., are: No. 1, a very silicious aplite (a micaless, granitoid rock); No. 2, also a silicious dike rock, containing pyrite; No. 3, basaltic rock; No. 4, aplite (same as No. 1). These rocks, No. 1 and 4, are the 'alaskite' of Spurr; No. 5, andesite; No. 6, granite; No. 7, limestone.

The rocks from Columbia, Nev., marked R E H M, are: R, amphibolite schist; it consists largely of feldspathic material and talc scales; it may have been originally diorite. E is diorite much altered; the hornblende is altering into chlorite and epidote; an occasional grain of quartz may be seen in the specimen. H is apparently andesite, but is much altered, the feldspar being much decayed. M is almost wholly quartz, and seems to be silicified rhyolite; this last rock may contain gold.

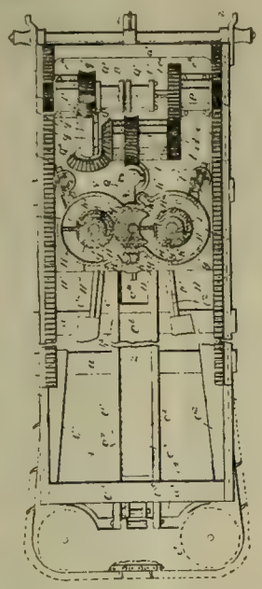
The rocks from Columbia, Nev., may be described as follows: The piece marked W is brown chert or jasper, a silicious rock stained by brown iron oxide. The glassy looking crystals are free quartz. This rock has resulted from the chemical alteration of some previously existing rock, possibly limestone, or even a silicious rock. The occurrence of the glassy quartz grains only illustrates a further stage of alteration of the rock. Free gold occurs in both the chert and the quartz. The samples marked L are limestone in which there are indistinct traces of fossils. There is no indication of the existence of petroleum in this rock, but ore deposits may occur at or near contact of intrusive rocks, if such exist in the region of the limestone. These ore deposits may contain lead, silver, copper, gold, iron and other minerals.

Mining and Metallurgical Patents.

PATENTS ISSUED MARCH 6, 1906.

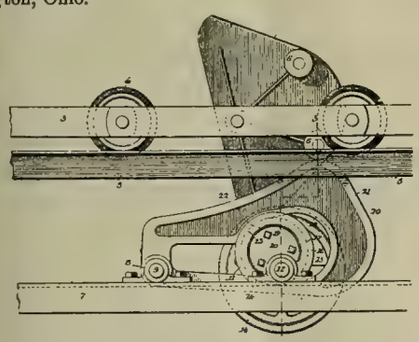
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

MINING MACHINE.—No. 813,508; E. R. Merrill, Columbus, Ohio.



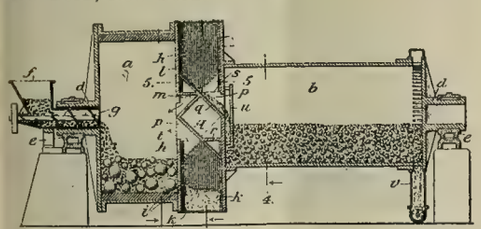
In mining machine, combination with bed, carriage adapted to move relatively thereto and cutter chain on carriage, of sprocket wheel engaging with and driving the chain, vertical shaft *l* to which sprocket is secured, worm on shaft for transmitting power to carriage-advancing mechanism, gear wheel on shaft, and two vertical engine shafts having their axes of rotation in plane transverse to carriage frame and in front of the driving sprocket wheel, casings of motors being arranged within the longitudinal planes of the sides of bed frame, rotary pistons connected with and rotating shafts and driving pinions on shafts engaging with and driving gear wheel *l* on sprocket shaft.

CONVEYER.—No. 813,474; F. R. Willson, Jr., Worthington, Ohio.



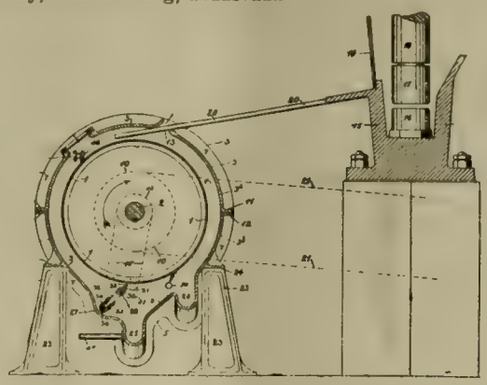
The combination with an elevator having swinging buckets, of tilting device for buckets in which is formed an open slot, eccentric mounted in slot and arranged to positively move tilting device both into and out of operative position, and means for operating the eccentric.

GRINDING-MILL.—No. 813,903; P. T. Lindhard, New York, New York.



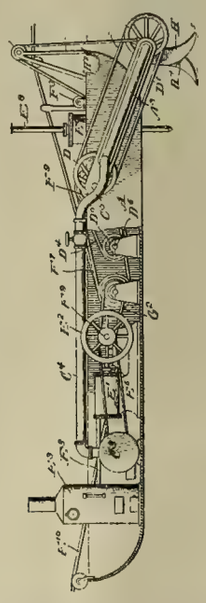
In a grinding-mill, the combination of grinding-drum, means to deliver thereto material to be ground, separator having compartment formed therein, means to deliver partly ground material to separator, and second grinding-drum, separator having means within compartment adapted to deliver finely ground material to second-named drum, and also having means within compartment adapted to return tailings to first-named drum.

AMALGAMATOR.—No. 813,780; D. Draper and G. A. Hay, Johannesburg, Transvaal.



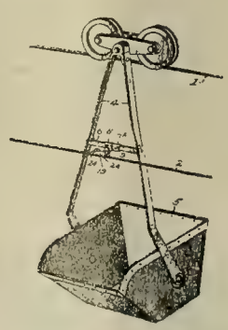
An amalgamating machine comprising drum, periphery of which is made the amalgamated surface, casing completely inclosing drum, casing being constructed with longitudinal inlet or slot above drum, and with recess or sump in bottom to receive concentrates removed from surface of drum, and with another sump or recess to receive amalgam when it is removed from surface of drum, revoluble brush arranged longitudinally of casing for cleaning amalgamated surface of drum, means for rotating brush, a scraper journaled longitudinally of drum and adapted to be brought into contact with amalgamated surface, means for traversing scraper longitudinally of drum in either direction, and water-spray pipe located beneath drum for washing concentrates off amalgamated surface of drum.

GOLD DREDGE.—No. 814,019; H. J. Clark, Boise, Idaho.



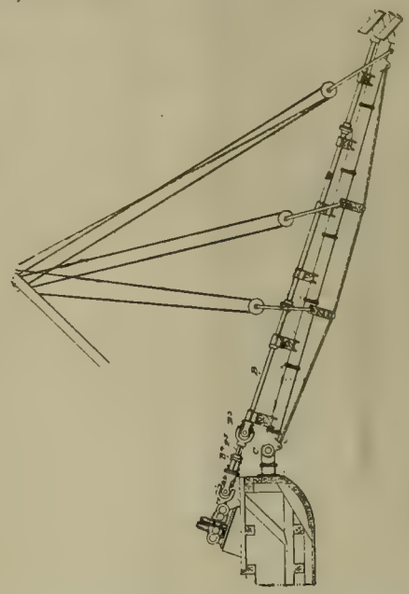
In a dredge, scoop provided with conducting space therein and reticulated face thereto, hollow hub communicating with space, means for creating suction within hub, means for oscillating scoop, swinging arms upon which hub is mounted, means for raising and lowering arms, and curved plates secured to outer faces of arms to form conducting passages upon arms communicating with hub.

TRAMWAY BUCKET AND ROPE CLIP.—No. 814,622; B. C. Riblet, Spokane, Washington.



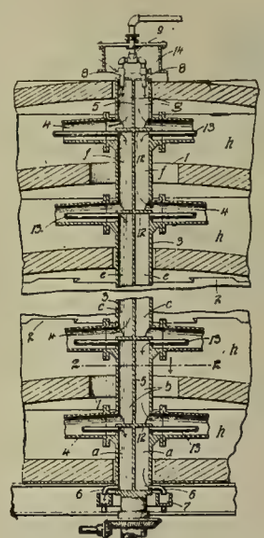
In rope and bucket clip, socket member secured to tramway bucket and body portion with ball at one end pivotally secured in said socket and attached at its opposite end to a traction rope.

DREDGER.—No. 814,204; N. R. Harris, San Francisco, California.



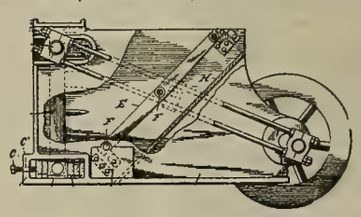
In dredger, cutter-shaft mounted upon a swinging ladder, driving means upon said dredger, universal and slip joints interposed between said cutter-shaft, and the driving means near the pivot of ladder.

ROASTING-FURNACE.—No. 814,298; F. Klepetko, New York.



In a rabble apparatus, a hollow rabble shaft having its passage-way divided into series of conduits, and means for independently supplying each conduit with suitable cooling medium.

ORE AND COAL CRUSHING MACHINE.—No. 814,085; J. F. Sauerman, Russellville, Arkansas.



In ore-crushing machine of the class described, suitable frame, reciprocating crusher-head mounted in frame, means for reciprocating crusher-head, and a back plate, back plate consisting of a plurality of separate bars, spacing rods on which bars are strung, means for adjusting the bars toward and from each other on rods, and supporting cross-beams independent of rods for sustaining the ends of the bars against the crushing strain.

PROCESS FOR THE RECOVERY OF PRECIOUS METALS FROM ORES, ETC.—No. 814,294; J. A. Just, Pulaski, New York.

The process of recovering precious metals from ores or materials containing metals which consists in subjecting ores or materials to action of nascent oxygen and an acid capable of forming compounds with oxides of precious metals formed and dissolving compounds.

Mining Summary.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

Special Correspondence.

LONDON, March 7.

Mr. J. H. Curle's letter on gold dredging which appeared in your issue of January 27 has attracted considerable notice here. His authoritative opinion "that the Oroville gravels—proved as they are—form the safest gold-mining venture in the world," naturally makes stockholders in Oroville Dredging, Ltd., feel pleased with themselves. Some particulars of this company in which London is so largely interested may be of use to your readers.

The company was formed in August, 1905, and registered in the State of Maine, U. S. A., with a capital of $3,500,000 in shares of $5 each, to work four concerns, namely: The Boston & California Dredging Co., The Boston & Oroville Mining Co., The Bear River Mining Co., and The Oroville Gold Dredging & Exploration Co. The first three are taken over, but although the Oroville Gold Dredging & Exploration Co. has also come into the deal, the formality of handing over the property is not reported as concluded. The present issued capital of the Oroville Dredging, Ltd., is 570,000 shares; the balance of 130,000 shares will be issued against transfer of the remaining property referred to. It is stated that there are four new dredges, of latest design and large capacity, under order. Until these are delivered no work is being done on the Bear River property, but there are three dredges in operation on the Boston and California ground, one of which is a large modern machine, and three on the Boston and Oroville. The working of these six dredges for the three months ending October 31, 1905, treated 990,682 cu. yd., which yielded gold worth $153,046, or an average of 15.44 cents per cu. yd. The operating cost during this period averaged 3.44 cents; and the renewals and repairs 3.22 cents, including abnormal charges owing to important replacements in one of the dredges. Royalties amounting to $4,555 in respect of Boston and California dredges No. 1 and 2 were paid, and after taking into the account Boston office expenses and the income of about $6,000 from the company's machine shops, etc., a net profit of $87,000 accrued. The first quarterly dividend of 12½ cents per share, or 10% per annum, was paid out of these profits on December 15. The returns which have been published since the end of October have fully maintained the previous average, and a second dividend at the same rate for the quarter ending January 31 has now been announced.

On the Oroville Gold Dredging & Exploration Co.'s property there are two dredges in operation, with an aggregate capacity of about 120,000 cu. yd. per month, one of them being of the largest type, and when this property is handed over, it is expected there will be a further increase in the returns.

Mr. W. P. Hammon in his report, May, 1905, estimated the contents of the four properties at 114,617,814 cu. yd., representing a net value, after deducting the cost of working, at 5c. per cu. yd., of £2,027,059. It is anticipated the company will continue to pay minimum dividends of 10% until the four additional dredges have been installed, and that thereafter the earnings will be upward of 20%, but it is intended to pay up to 15% during the remainder of the company's life—estimated at about 15 years—and from the surplus profits to set aside a sinking fund to provide the return of the capital when the properties are worked out.

The Exploration Co., Ltd., since its reconstruction in 1904, after coming to grief over financial schemes which had nothing to do with mining, has, under the management of Mr. R. T. Bayliss, achieved a decided measure of success. Of its total capital of £750,000, the company's investments taken at cost, which by a coincidence happens to be within a few hundreds of pounds of the marketable values, account for a total of £693,114. It is of interest to notice the principal of these investments. They comprise: £178,756 in South African gold mining shares; £107,378 in town property and buildings at Johannesburg; £110,737 in El Oro, Mexican Mines at El Oro, and Somera Gold Mining Co.; £62,535 in Tomboy and other gold mines in the United States, and £43,313 in American copper mines. The net profit of the company for the year 1905 was £67,813. This added to the previous balance of £30,261 made a total to credit of £98,074, from which a first dividend of one shilling per share—absorbing £37,500—was declared at the annual general meeting held last week. During the past year the company has extended its sphere of operations to the development of a copper mine in Peru, and the directors have formed a South American Exploration Company to deal with interests in that part of the world, especially in Peru and Bolivia. In the course of his speech at the meeting, Mr. Bayliss mentioned incidentally that in spite of the present depressed state of Kaffir shares, he was of opinion they were worth buying now and he anticipated a profit from those the company had purchased.

The annual report of Jumpers Deep Co. to September 30, 1905, is of a retrograde character. From 240,209 tons of ore sent to surface 23.03% was discarded in sorting; 184,358 tons were milled from which gold to the value of £265,432 was recovered, or an average yield of 28s. 9½d. per ton, being 3s. per ton less than for the previous year, the stoping from ore reserves having proved of lower grade than had been anticipated from the sampling; there was also a falling off in development values and width. Working costs increased by 3s. 6½d. per ton. Net profit, £25,135. The developments amounted to 6,850 ft., of which 72% in reef formation. Ore reserves estimated at 428,342 tons.

The New Rand Syndicate, Ltd., is beginning to excite enquiry, but little information, except of a general character, has so far been vouchsafed. It is said that developments taken in hand over a year ago are proceeding with unusual vigor. The formation is described as a ridge some 1,000 ft. above the surrounding country, and the deposit is supposed to extend for 14 miles. The ridge has been pierced by a number of tunnels at 100, 600, 800, 900 and 1,000 ft. below the top of the outcrop, and it is said that astonishing results have been obtained, the lowest value being about one ounce per ton.

The report of the London & West Australian Exploration Co., Ltd., for 16 months to December 31 shows a net profit for the period of £21,265. This has been written off the debit balance, which arose out of the disastrous crisis in 1901-2, thereby reduced to £5,953. The directors state that during the year 1904-5 no important discoveries were made in West Australia, and no revival of public interest took place in the mining industry to offer special opportunities for the company's operations.

According to the portion of British mining statistics for 1905, which has appeared, the total output of coal was 236,111,150 tons—an increase of 3,699,366 tons over 1904; ironstone 7,860,969 tons—an increase of 303,236 tons.

Is Cornwall going to benefit by the restriction of the mining industry in South Africa? The archives of Somerset House reveal the fact that Tywarnhaile Syndicate, Ltd., was registered some eight months ago with a nominal capital of £22,500, of which £7,500 was called up. Amongst the leading shareholders are found the Consolidated Goldfields of South Africa for 5,293 shares and the South African Gold Trust for 4,000. The property is within a mile of the Atlantic and is situated in a district which flourished some 50 years ago, extending from almost the sea-shore on the north to Scorrier, some four or five miles to the south.

At the Basset Mines, Ltd., annual meeting last week a profit was reported of £6,408 from the gross income of £58,946. The milling for the year amounted to 49,587 tons, yielding an average of 34.7 lb. black tin per ton, an increase, respectively, of 5,719 tons and 3.4 lb. over 1904.

Good progress is shown by Dolcoath for the half year to December 31. Although the quantity of tin ore crushed—48,472 tons—was slightly less than for the previous half year, the grade was better—40.06 lb. per ton against 37.20 lb.; 866 tons of black tin were sold and the profit realized was £22,385, against £12,340 for the half year to June 30. The proceedings at the annual meeting last week were of unusual interest. The manager, Capt. A. Thomas, reported that the mine was in a better condition underground with a finer surface equipment and stronger financial position than for many years past. Favorable developments were proceeding in the upper levels, but the point of paramount importance was the recent improvement in the bottom of the mine. In the winze 22 fathoms below the 470-fm. level the lode had been cut through for a width of 12 ft., producing 1½ cwt. tin per ton of stuff; the lode would be found still wider as the stope above gave a width of 4½ to 5 fathoms. Capt. Thomas stated his intention to continue his method of expressing the lode-values in pounds of tin per ton instead of in the old system of pounds sterling per fathom, which he said veiled the facts in undesirable obscurity. Intelligible information should be given to the public outside the County, who are now giving more attention to Cornish mining than formerly. With regard to the ore reserves, Capt. Thomas stated that owing to the nature of the formation, frequent instances of large areas of impregnation of tin oxide without any distinct hanging or foot-wall—any estimation of ore reserves in Dolcoath must be somewhat problematical, but making reasonable reservations, he put the workable reserves of tin-bearing ground at 270,000 tons. As an evidence of the increased interest taken by the public in the mine since the adoption of limited liability, it was stated that the shareholders now number 1,673, as against 400 under the cost-book system.

CALUMET, MICH., March 17.

Mining operations in No. 5 shaft of the Tamarack mine were resumed this week after an idleness of three months, caused by the fire which started in No. 2 shaft. The drifts connecting No. 5 with No. 2 at the twenty-ninth and thirty-first levels were bulkheaded to prevent the poisonous gases lingering in the latter from gaining entrance to the workings filled with men in No. 5. The gas still lurks in remote and inaccessible workings of No. 1 and 2 shafts and it is problematical when conditions will permit the resumption of operations underground from these shafts.

The situation at the Tamarack is annoying. While the fire caused a material loss in the mine of probably only a few hundred dollars, being extinguished promptly, the gas given off by the burning timbers has prevented the usual operations, and caused a decrease in copper production of not less than 3500,000.

With No. 5 shaft in commission the Tamarack will be enabled to increase its output and operations will be pushed with all possible speed until they can resume in No. 1 and 2 shafts. No. 3 shaft, at the North Tamarack branch, is the only opening that has been in commission during and since the fire. This is the deepest shaft in the world and has been shipping 1,100 to 1,200 tons of rock daily.

Sinking in the Allouez's No. 1 shaft is approaching the seventh level which it is expected will be reached early next month. Drifts were recently started from the shaft at the sixth level and excellent ore was revealed. Particular interest is felt in the work at the sixth level, as this is the first level at which the company will be able to open the Kearsarge amygdaloid bed to the full extent of its property. Early in the spring it is likely the Allouez management will resume work in its No. 2 shaft, which has been at a depth of fifty feet for several months. This shaft should intercept the Kearsarge lode and become a producer in two years.

Reports to the effect that there was to be a revival of activity at the Phœnix Consolidated property in Keweenaw county was apparently ill-timed. Likewise there appears to be no truth in the report that the Calumet & Hecla Co. was negotiating for the mine. The Phœnix in 1905 produced 273,219 lb. of refined copper, as compared with 1,162,201 lb. in 1904. It will not have any standing among the producing mines this year, as no work has been done since last summer.

Preparations for spring activity on the lands of the Keweenaw Copper Co. in Keweenaw county, are being made. The exceptionally light winter will permit an early start in the test-pitting, cross-trenching and other surface exploratory work which cannot be done to advantage during winter. An office building is being erected on the company's Mandan property. The first drill is now working on the south end of the Mandan tract and has reached a depth of 75 ft. in search of the Kearsarge lode. The other diamond drill is on the Resolute where the hole has been put down vertically for 350 ft. in search of the Montreal River lode. The Montreal River bed has already been found at other points and the approximate strike-line of the formation across the property determined, and it will be further tested during the summer. Captain Thomas Hoatson of Calumet is mining director of the Keweenaw Co. He was formerly in charge of mining work for the Calumet & Hecla Mining Co., but resigned a few years ago, his extensive interest in Arizona and elsewhere demanding greater attention. He is a director and vice-president of the Calumet & Arizona mining Co., and the four Bonanza Circle mines at Bisbee, Arizona.

Captain James Hoatson, president of the North Butte Mining Co., is another member of the directorate of the Keweenaw Co. With Thomas F. Cole and the two Hoatsons in the company, the Keweenaw will not lack for able mining direction.

Sinking in the shaft at the Superior mine, in which the Calumet & Hecla Mining Co. recently secured a heavy interest, has reached the third level. Some time will now be consumed in crosscutting to the Baltic lode. No other work is under way at the property.

BUTTE, March 19.

The February copper production of the Butte district amounted to 26,129,600 lb., the apparently small total being due to the short month; that the mines of the Trenton Co., one of the amalgamated properties, have been closed, and that the Clark mines yielded a decreased quantity of ore, owing to the fact that the Clark concentrator has been destroyed by fire, and some of the ore, a lesser quantity than formerly mined, is now being shipped to the Washoe smelter. The February daily and monthly average of ore mined in Butte and the average yield of copper per ton of ore were as follows:

Companies.	Daily tons of ore.	Monthly.	Lb. copper per ton.
Boston & Montana	3,600	100,800	70
Anaconda	3,550	99,400	66
Butte & Boston	525	14,700	62
Washoe	450	12,600	65
Parrot	500	14,000	68
North Butte	1,000	28,000	120
United Copper	1,500	42,000	65
Clark's Original	1,000	28,000	70
Pittsburg	200	5,600	78
East Butte (lessees)	125	3,500	160
Miscellaneous	400	11,200	70
Total	12,850	359,800	

The total daily and monthly yield of copper was as follows:

Companies.	Daily Lb.	Total Lb.
Boston & Montana	252,000	7,056,000
Anaconda	234,300	6,560,400
Butte & Boston	32,550	911,400
Washoe	29,250	819,000
Parrot	34,000	952,000
North Butte	120,000	3,360,000
United Copper	97,500	2,730,000
Clark's Original	70,000	1,960,000
Pittsburg	15,600	436,800
East Butte (lessees)	20,000	560,000
Miscellaneous	28,000	784,000
Total	933,200	26,129,600

The sale of a controlling interest in the Butte & London Mining Co. to the Venture Corporation of London is locally regarded as a good thing for the Butte district, as it brings into the field another big operating and promoting company. The deal was made by individual holders of the majority of the stock, after an engineer of the Venture Corporation had spent a week in Butte making an examination of the Butte & London property and surrounding mines. The Butte & London ground, consisting of 113 acres, lies between the North Butte mines and the mines of the Butte Copper Exploration Co. For the present there will be no change in the local management of the Butte & London, as the new owners are satisfied with the work and progress being made. The three-compartment shaft has reached a depth of 140 ft. and will be sunk to 1,500 ft. before crosscutting is done. The Venture people have for some time been trying to get a foothold in Butte district and the Butte & London proposition offered the opportunity.

A number of Amalgamated mines in Butte shut down two days last week owing to extreme cold, which froze up the water flumes at the Washoe smelter at Anaconda. On account of ice running in the flumes the concentrator could not be operated and the ore-bins and cars were soon filled with ore. The weather moderated and the concentrator resumed operation after a brief shut-down. The Boston & Montana smelter at Great Falls was not interrupted, although the water supply there was also frozen, but that company has a modern steam plant, as well as a water-power plant, and when the water-power froze up the steam-power was turned on and was used during the continuance of the cold spell.

The new hoisting engine for the North Butte Co. has finally reached Butte and is being placed in position.

Another copper mining company has been incorporated, called the Butte Copper Co. Its promoters are Mayor John MacGinniss, W. V. Lawler and E. H. Sherman, all of Butte. The new company owns two-thirds interest in the Robert Emmet No. 1 and Robert Emmet No. 2 mines; all of the Anselmo No. 1 and the Anselmo No. 2 and all of the Trifle. The ground lies for 2,300 ft. on the extension of the Gagnon and Stewart veins, just west of the Gagnon mine of the Trenton Co. The Butte Coalition Co. owns a third of the Emmet mines, as successor to F. A. Heinze. There is a shaft 300 ft. on the Emmet, and the Anselmo mines also have some development. The latter produced about $500,000 in silver some years ago. The Emmets were worked until recently under lease and option, but the parties holding the option were hampered by a lack of funds and inability to handle the water. When they quit it was reported they had cut into a body of 7% copper ore. There

seems to be little doubt these mines are on the Gagnon lead. The Silver King and Plymouth mines, silver properties, which have for years been tied up in litigation, adjoin the Anselmo and are on a branch of the Anselmo vein.

Heinze's Butte followers have a new report about his future intentions regarding United Copper, to the effect that he will transfer the Lexington group, at present an independent concern, known as La France Copper Co., and that he will take up an option on the Blue Bird silver mines west of Butte. The Blue Bird once produced silver, and was owned by the Van Zandt people of New York, but, because the mines proved disappointing, Ferdinand Van Zandt committed suicide. This was about 15 years ago. Since then nothing has been done on the property except to dismantle it and tear down one of the finest surface plants in the State.

The reports among the Anaconda miners are persistent that the big vein which some months ago was cut on the 2,200-ft. level of the mine has also been cut on the 2,400-ft. level, and that the ore there is not nearly so rich as it was on the 2,200, though the orebody is fully as extensive. The officials, however, deny that the vein has been cut again, declining to discuss the matter or to give out any information at all regarding it.

The Butte Copper Exploration Co. has the water out of the shaft of the Six O'Clock mine and will shortly resume active development.

The Raven Mining Co. is opening the north vein on the 1,500-ft. level. The south vein on the 1,200-ft. level is being developed, and the ore found in the crosscut maintains its richness and is growing wider in the drifts.

The east Butte Co.'s leasers are hoisting 125 tons of ore daily that runs from 8 to 12% copper, on which the company is paid a royalty of 25 per cent.

TORONTO, March 14.

The experiments in the electric smelting of iron ore, which have been carried on at Sault Ste. Marie for about two months, were completed on the 5th inst. They are reported entirely successful in demonstrating that iron ore can be economically treated by the electric smelting process. Dr. Eugene Haanel, Canadian Superintendent of Mines, who supervised the experiments, is preparing a detailed report which will shortly be published giving full particulars. In an address before the Canadian Club of Toronto on the 12th inst. Dr. Haanel gave an interesting account of the tests, showing what had been accomplished in demonstrating the commercial practicability of the electric process.

He prefaced his remarks by a review of the existing situation in Canada as regards the rapidly increasing demand for steel and the resources which Canada possessed to meet these requirements. Large deposits of iron ore existed in the central districts, but the coal essential for coke was only found in the extreme East and West so that the country was at a disadvantage in the manufacture of iron and steel by the ordinary methods. This rendered it evident that the question of electric smelting was one of supreme importance to the industry. After recounting the results of enquiries made by the commission appointed to investigate the subject in Europe, where they witnessed experiments at La Praz and Livet, in France, Dr. Haanel pointed out that before the feasibility of electric smelting in Canada could be determined the following points, which could not be settled by European experiments, required to be determined.

Can magnetite be successfully smelted?

Can iron ore with considerable sulphur content, be made into pig iron of marketable value?

Can charcoal be substituted for coke, which must be imported?

What is the exact amount of electric energy required per ton of pig iron produced?

The experiments at Sault Ste. Marie were accordingly arranged with a view to determine these points. The work of preparing for and directing them was entrusted to Dr. Heroult of La Praz, France, and the co-operation of the Lake Superior Power Company, was secured. Dr. Heroult designed a furnace of 250 h.p. capacity, and a transformer to convert the electric current from 2,200 volts to 40, as required by the experiments, was procured from the Westinghouse Co. Electrodes, 5 ft. long, and 16 in. square were ordered from Germany. The furnace was of simple construction, the upper half being lined with fire brick and the lower half with carbon. An electric cable was attached to the carbon lining and to the transformers, to bring the current in contact with the ore. Peat charcoal was used and no difficulty was experienced, the furnaces working quietly and regularly.

The experiments on Canadian ores were fairly begun about the middle of February and lasted day and night until March 5. In all 150 casts were made yielding 55 tons of pig iron. For the first experiment the ore tried was hematite such as is used by the Algoma Steel Co. The remaining experiments were conducted with different kinds of Canadian magnetite, all of which, with one exception, were high in sulphur. It was found that the magnetite could be smelted with as much facility as hematite. Analysis of the iron produced, proved that although the slag was not particularly basic, the sulphur could be caused to pass into the slag, resulting in a pig iron containing a few thousandths of one per cent sulphur. Many magnetites are too high in sulphur to be handled by the blast furnaces, and thus have, so far, no commercial value. But it has been proved by these demonstrations that the best of pig iron can be made from ores containing as high as one per cent of sulphur. A blast furnace will not, as a rule, use an ore containing one-tenth of one per cent sulphur, and it therefore requires an ore which cannot be got at a low figure. While the Algoma Steel Works pay $4.50 per ton for the hematite ores they use, a pig iron of equal value and lower in sulphur content can be made by the electric process from sulphurous ores which are now obtainable for $1.25 per ton. The cost per ton of pig iron produced for electrodes, which in the French experiments amounted to 77c., had been reduced to 30c. Dr. Haanel estimated that the cost of developing electric energy from water power adjoining the iron ore deposits would be from $4.50 to $6 per horsepower yearly. He anticipated that a means would be found of utilizing the carbon monoxide, which now escapes, with the result of increasing the output by one-third or even one-half and if this took place, blast furnaces could not compete with electric furnaces even if coke were cheaper than at present.

Experiments with roasted and briquetted nickeliferous pyrrhotite containing 1.6% of sulphur were equally successful, furnishing a ferro-nickel pig containing 4½% of nickel and virtually free from sulphur. The experiment proved so satisfactory that the Lake Superior Co. are desirous of acquiring the plant for the purpose of converting their stock of briquetted ore into ferro-nickel pig.

In conclusion, the speaker emphasized the special importance of the utilization of ores with high sulphur content in view of the serious question which has arisen as to how long the present supply of blast furnace ores is likely to last. When these ores were exhausted and none but sulphur ores and titaniferous ores were available blast furnaces would necessarily be supplanted by the electric furnace as that alone could successfully treat such material.

DENVER, March 18.

The stormy weather accompanied by heavy falls of snow, which set in on March 1, and which has since prevailed throughout the State with unusual severity, has caused prodigious snowslides that have demolished and swept away mills and mine buildings valued at hundreds of thousands of dollars, and destroyed many lives. The storm, continuing at the present writing, bodes unprecedented disaster. It is too early to record the reported losses, for the unverified rumors of havoc seem almost incredible.

Construction of the Argentine Central railway was discontinued on the 14th inst., on account of the storm. It is the intention of the projectors to resume work on April 15. From the starting-place at Silver Plume, Clear Creek county, to the top of Mt. McClellan, its ultimate terminus, by a tortuous route, is a distance of 16 miles. The grading is nearly finished and the road is now in operation for a distance of nine miles from Silver Plume, which brings it within the productive area of the Argentine district. When completed the road will reach an altitude of about 14,000 ft. above sea level, and trains will be run over the ordinary two smooth rails on an average grade of four per cent. The road penetrates a promising mining section that years ago produced considerable ore, but which, since the decline in the price of silver and until quite recently, has been much neglected. Now, however, fresh development work is being prosecuted. The Waldorf Mining Co. is opening up and producing ore from a number of its properties, notably the Santiago and Manhattan mines. The Vidler tunnel, now in 800 ft., is projected to develop the Pennsylvania and Montezuma mines, the latter, one and one-half miles distant on the tunnel line, from its portal. The last four miles of the railroad is intended exclusively for tourists. The grandeur of the scenery along the route and from the top of Mt. McClellan is unsurpassed elsewhere in the Rocky mountains. W. H. Stillwell, formerly division superintendent of the Rock Island road and recently with the Uintah railway, is to become general manager of the Argentine Central railway.

The United Light & Power Company of Clear Creek county will hereafter be known as the United Hydro-Electric Company. The company has recently bought Heine boilers of 500 h.p. capacity, and new electric generators and accessories to double its present capacity. When the new machinery is erected, a 2,000 h.p. can be developed at the Georgetown plant; water and steam are utilized for prime powers. The Telluride Power Co., the pioneer electro-power company of the State, and the first to introduce high voltage currents for long-distance transmission in the mountains, is making improvements which, when carried into effect, will probably make it the largest producer of electric power in the State. The company has three generating stations in operation—two in San Miguel county, that is, one at Ames, another at Ilium, and a third at Ouray, in Ouray county. The fourth station site is selected, but its location has not been made public, and the fifth is under consideration. The accessions now under construction will bring the total capacity up to nearly 12,000 h.p. The Ames station, now producing less than 2,000 h.p., will have a complete new plant of 6,000 h.p. capacity. Water is the only initial power used by this company. Major Cooper Anderson, of Telluride, the executive officer of the company, has charge of the new construction.

Anent, the bringing of Vincent St. John to Telluride to stand trial for murder; the hysterical utterances of some of the Colorado papers would give color to the belief that they were paid to assassinate the State of Colorado. It is a reflection upon the mental standard of Colorado citizens that certain papers, continually given to misrepresentation and inciting bitter animosities, should receive support and be able to sell their wretched sheets. Crime is hateful, but the calculating mixers of the devil's broth that incites to crime are a thousand times more loathsome than even hired assassins. The real origin of the so-called labor trouble has never been published. We are not advocating the principles of the Western Federation of Miners; nevertheless, it would be a good trade if Colorado could 'swap' off her crop of over-ripe politicians for the Western Federation of Miners; the loss might prove a gain.

SALT LAKE CITY, March 20.

The construction of the Utah Copper Co.'s new Garfield concentrator is progressing satisfactorily. The first of the steel buildings to go up will be completed by the end of the present week. The contractors, the Minneapolis Steel & Machinery Co., have commenced the erection of the power plant, and the steel structural material for the main concentrator building is arriving on the ground. Bad weather has retarded the work. George O. Bradley, of Salt Lake, is chief engineer.

Notwithstanding stormy weather and bad roads, shipments from Park City last week were up to normal, the total output being 5,050,000 lb., the Silver King heading the list with 2,000,000 lb.; the Daly-Judge next with 970,000 lb. of ore and concentrate and 654,000 lb. of zinc middling; the Daly-West sent out 1,150,000 lb. of ore and concentrate, and the Kearns-Keith Co. and lessees made up the balance. The Little Bell Co. will probably make its initial shipment this week, and can be counted on regularly thereafter.

When Daniel Guggenheim, president of the American Smelting & Refining Co. visited Salt Lake recently, he made the statement that the American Smelters Securities Co. had purchased enough stock in the Balaklala Consolidated Copper Co. to give it a control; that the output of that California mine would be shipped to the new smelter, to be built near San Francisco, for treatment. This gave the impression that the original plans of the Balaklala company, which involved the building of a smelter at the mine, would be abandoned. This is not the case, however. Chief Engineer Robeson T. White, who has returned to the Salt Lake offices of the company from New York, has informed the writer that he has instructions to proceed to draw plans for a copper matting plant, having a capacity to treat 750 tons of ore from the Balaklala mine daily; that additional facilities will be provided for the treatment of custom ores. The matte product is to go to the San Bruno plant of the A. S. & R. It was the original intention of the Balaklala Co., before the Guggenheims became a factor in its management, to build a plant of 500 tons capacity and to produce blister copper.

There is a movement on foot for a consolidation of a number of mines in the Thayne's cañon section of Park City. It is proposed to join the Odin, California, Comstock and Silver Bell properties, and prospects of a consummation of the deal are said to be fair.

Although the recent conference between Daniel Guggenheim and Samuel Newhouse relative to a union of the Utah Copper and Boston Consolidated mines at Bingham failed in its object, there is a possibility that negotiations will be opened again later.

Important developments have been made in the Butler Liberal mine at Bingham during the past week. The main tunnel has encountered a large body of high-grade lead ore. An average sample taken across two feet of the ledge assays eight ounces in silver and 60% lead.

S. H. Roundy, manager of the Bull Valley Mining Co., operating an onyx property in Washington county, Utah, has reported the discovery of a two-inch streak of mineral in a white quartz vein. A sample was forwarded to Washington, D. C., where it was pronounced to be gibsite. Other deposits of the mineral in the United States are in Massachusetts and New York. Gibsite is an aluminum hydrate. Mr. Roundy resides at Benson, Cache county, Utah.

The engineers who have been conducting examinations of the properties of the Bingham Consolidated have completed their labors.

The management of the Yampa mine, at Bingham, has decided to equip that property with a two-mile aerial tramway, connecting the mine with the smelter in lower Bingham. At present, the company depends on the Copper Belt Railroad for transportation facilities, which have not always been satisfactory.

The St. Joe Mining Co., which is driving a tunnel on its Bingham properties, is in 2,725 ft. Considerable mill ore has been encountered. R. A. Hasbrouck of Salt Lake is manager.

In the hearing of the smelter-smoke cases that have been pending for some time before Master in Chancery S. H. Lewis, the defendant smelting companies involved began submitting their evidence during the close of last week. Numerous mine managers were placed on the stand to show that tens of thousands of people in Utah and surrounding States are dependent on the smelters operated in the Salt Lake valley, and that if the smelters were ordered closed, the mines would thereby be forced out of business.

At the annual meeting of the shareholders of the West Quincy Mining Co., with properties at Park City, G. D. B. Turner, James H. Moyle, W. H. Dodge and N. Treweek, of Salt Lake; Dr. E. A. Van Norman, of Los Angeles; J. R. Rand, of New York, and Sherman Fargo, of Park City, were chosen directors. Mr. Turner was re-elected president and general manager.

The Starless copper property at Bingham, owned by E. A. Wall of Salt Lake, is to be the scene of vigorous exploration and production. A compressor plant is to be installed. Ore will be sent to the mill within sixty days.

Excavating for the new works of the Utah Smelting Co. near Ogden is about to be started. A railroad spur to connect with the tracks of the Oregon Short Line, Southern Pacific and Ogden & Northwestern is being built. The initial unit will consist of a copper matting furnace of 150 tons daily capacity, and will be furnished by the Colorado Iron Works Co. through Clement & Strange, Salt Lake agents; the Allis-Chalmers Co. have the contract for the sampling mill. David Eccles, of Ogden, is president of the smelting company.

The West Tintic Mining Co. has filed articles of incorporation to operate in the West Tintic mining district. J. H. Burrows is president, W. F. Shriver vice-president, J. E. Driscoll, of Eureka, Utah, secretary and treasurer.

Last week's ore shipments from the Tintic mining district amounted to 156 carloads, the shippers and amount being:

Gemini	21	Scranton	1
Centennial Eureka	54	Bullion-Beck	5
May Day	2	Ajax	2
Eureka Hill	9	Black Jack	1
Beck Tunnel	8	Carisa	2
Eagle & Blue Bell	7	Lower Mammoth	3
Uncle Sam	3	Mammoth	13
Swansea	2	Grand Central	15
Yankee	2	Victoria	3
Dragon Iron	3		

The ore and bullion settlements at the close of business last week were reported at $415,500.

The unusual activity of southern Nevada is being carried into southern Utah, and many old camps are again attracting attention, and new discoveries are being reported from numerous districts. The construction of new railroads through the southern portion of the State is aiding materially in this renewal of mining activity.

ARIZONA.

Cochise County.

A strike was made recently on the Elizabeth claim, close to the Elizabeth, Alta Vista and Keystone, near a contact of quartzite and lime, in a tunnel at a depth of 20 ft. The ore from this strike is reported to assay 2,800 oz. silver, 30.7% lead and rich in gold. The vein is three feet in width. The tunnel is in 45 feet.

Water has been encountered at the Hoatson at Bisbee and sinking has been discontinued for the past week while a station is being cut on the 1,050 level. Water was encountered in the Hoatson shaft at a depth of 1,120 feet. At the station on the 1,050 a large tank is to be installed. Sinking pumps will raise from the bottom to this tank and from this level the water will be handled with bailers to the surface.

Sinking will be resumed at the Hoatson, and the shaft put down to the 1,150 level, when drifting will be started. When sinking was discontinued, water was coming into the shaft at the rate of fifty gallons per minute. When the Hoatson shaft reaches the 1,150, which corresponds to the 1,000 on the Junction, a drift will be run to connect with the Junction, a distance of 2,000 feet, work on the Junction end having already been started. In one month Jack Hinckley sunk the shaft 162 fect and the men at the Hoatson received a bonus for every foot in excess of 100. A big broom mounted on top of the shaft-house tells the story.

Yavapai County.

(Special Correspondence).—A meeting of the Yavapai Commercial Club March 14 was in the nature of a business men's meeting. The subject under discussion was a 'New era in Yavapai county.' This subject covers the condition of affairs in northern Arizona, as to mining, for never in her history has there been so much legitimate mining going on as at present. This is not confined to any particular district, for every district in the county is active.

The Bradshaw mountains are the scene of the greatest activity as far as large enterprises are concerned. The building of the Arizona and California railroad—a cut-off of the Santa Fe system from six miles north of Wickenburg on the Santa Fe, Prescott and Phœnix railway, to the main line near Parker, California—a distance of 105 miles, is facilitating the development of this richly mineralized section. The line is now in operation for 50 miles, to Salome, and with the recent completion of the several miles of tunnel through the Granite mountain the work of extending to the Colorado river will progress rapidly. The first 55 miles of the road is through McMullin valley, 15 miles wide, the road being equi-distant from the Harcuvar range to the north, and the Harqua Hala to the south. On penetrating the Granite mountains at the head of the valley, the route is on an easy grade to the river.

Both to the north and south of the line from 5 to 53 miles, there are sections in which profitable gold mining has been heretofore, and is now being carried on, and which will now come into greater prominence, owing to their easier accessibility. Among the older camps are Harrisburg, where are the Harqua Hala mines, and the Socorro mine, which the past few years has been profitably operated. In other portions of the Harqua Hala range there are other properties from which high-grade gold ores have been mined, while scores of properties, the ores of which could not be profitably handled on account of lack of cheap transportation facilities, will be developed. To the west of the Harqua Hala camp, and within 25 miles of the railroad is Quartzsite district. Still further west and near the Colorado river is the King of Arizona mine at Kofa, which has been productive of gold for years past. At Quartzsite the placering of gold gravels and the stamping of the free-milling gold quartz ores have been carried on, but comparatively little attention has been given to the workable deposits of lead-silver, copper-gold and cinnabar known to exist, nor to the lower grade gold ores of both free milling and refractory character.

The depth attained in any of the older mines has been inconsiderable, the deepest being the Harqua Hala. While the important ore deposits in the Harqua Hala, Granite and Quartzite ranges are gold, copper predominates in the Guadalupe range to the south of the line, and in the Harcuvar and other mountains to the north. The importance of the copper deposits of the country about Bill William's fork, the dividing line between Yuma and Mohave counties, has long been realized, and some high-grade copper-ore shipments are recorded. With the approach of the railroad there is a noticeable increase of operations in that section.

Several miles to the south of the Bill William's fork an important gold strike is reported on the Carrigan-Rogers properties on Black mountain, twenty-five miles east of the Colorado river. For a distance of more than a mile with a width of from thirty to fifty ft., free gold quartz ores have been broken at the surface and in shallow prospect holes. Systematic development is now under way by the Clara Gold & Copper Mining Co., owning the Carrigan-Rogers group, as well as by other companies and individuals. A postoffice known as Clara has been established in the camp, which is now reached by fairly good road from Wendendale, the most important town on the operated line of the railroad, 45 miles to the south.

Wendendale, from its convenient location as regards Pinetahachi pass of the Harqua Hala mountains, and the Cunningham pass of the Harcuvar mountains, through which access to the eastern half of Yuma county is had, has become a supply point of importance. At the Colorado river terminal of the road a town has been started, and it is likely that several distributing centers will be established between Salome and the river. At Wendendale (railway station, Wenden) the Wendendale Gold Mining Co. has in contemplation the erection of a sampling plant to facilitate the shipping of small lots of copper-gold and gold ores now available in the several tributary districts.

From the Cunningham Pass section several shipments to the Humboldt smelter have been made, one lot of 18 tons from the M. E. Josephi property returning $500, the ore carrying 15% copper and $12 gold. Several other companies and individuals are making ready small shipments.

From the Oregon-Gilt Edge group of the Arizona Gold Mining Co., of which Dr. O. L. Geer of Martinez is manager, a shipment of high-grade ore is being sacked. The property is in Maricopa county, four miles south of Golden station on the railroad.

In the Harcuvar mountains, and reached from Bullard station to the east of Golden, is the Bullard mine, in which large bodies of ore that carries 7 to 10% copper and $10 in gold and silver are said to be opened. It is owned by the Bullard Brothers of Martinez.

The Socorro Gold Mining Co.'s mine is eight miles southwest of Wendendale. It is equipped with a 20-stamp amalgamation - concentration - cyanidation plant, which is in operation under direction of Manager F. C. Smith. This property is to the north of Harrisburg, while the Harqua Hala mine, which is again to be worked, lies six miles to the south. The postoffice of the Bill Williams' Fork country is Planet.

A partial list of developing properties in regions tributary to the A. & C. railroad is here appended: Signal Copper Co., Newton Evans, manager; Wendendale Gold Mining Co., O. E. Young, manager, and H. B. Hanna, assistant manager; Oro Cobre Gold & Copper Co., Mark Murphy, manager; Bullard Copper mine, Bullard Brothers; Victor and Belle Crown Mining Co., R. R. McDonald, manager; Della group, L. B. Pouge, owning operator; Liberty Gold & Copper Co., Frank Burns, manager; Clara Gold & Copper Co., J. E. Rodgers, manager; National Gold & Copper Co., Wolfram Copper Co., Continental Consolidated Mining Co., Ben Blanchard, manager; Planet Mining Co., D. Jones, manager; Josephe Torres group, Keyes group, San Marcus-Salome Development Co., W. S. Pratt, manager; Socorro group, Dr. O. L. Geer, owner; Mount Straub group, Aker Brothers; De Monte group, Mineral Belt, and Indian Queen groups, operated by O. L. Geer; American Mining & Smelting Co., and Amalgamated Gold Mines Co., O. A. Pease, manager.

A stock exchange was organized in Prescott March 12, and steps taken to equip offices and to operate a strictly up-to-date exchange, giving particular attention to stocks in the Southwest.

Prescott, March 19.

At the Cleopatra, General Manager Hull is grading for the new smelter. The work now being done in the mine is giving satisfactory results. —— General Manager C. W. Clark, of the United Verde, says that within one month his company will have another large furnace completed and at work. Mr. Clark also says they have been bothered by bad coal and they are considering the use of oil.

CALIFORNIA.

Calaveras County.

It is reported that the Penn copper mine, near Campo Seco, is to be connected with the railroad by a spur built from Burson, near Valley Springs.

It is reported that the Gwin mine is looking better than at any period in its history. Last month the gross output was nearly $50,000, and a dividend of 25c. per share declared. The improvement in this property is having an important influence on mining in that section, both on the Amador and Calaveras side of the Mokelumne river.

Oliver Rodgers & Co., of Boston, have secured control of the Lloyd mine at Central Hill, four miles west of San Andreas. The property is equipped with a 60-h.p. boiler, hoist and mill, and with nearly all the machinery necessary to handle 100 tons of gravel a day. A new pump will be installed. In sinking the incline shaft they struck the Round Wash channel nearly in the center, and a crosscut was run, and 100 feet of drifting done, proving the channel at this point to be 240 ft. wide and the gravel from 10 to 12 ft. deep. There is nearly a mile of the Round Wash channel on this property, and wherever this channel has been struck it is reported to have been rich. The incline shaft has been re-timbered and some work done on the shaft which taps the Flat Wash channel, and a good prospect of gold is being found at the foot of the shaft. The Flat Wash channel has never been a wide channel, but the wash has been rich, loose, uncemented gravel that does not require milling.

Kern County.

The independent oil producers of the Kern river and Coalinga fields are planning for a shut down in order to obtain better prices for their products. Many contracts between the producers and oil companies will expire in May, and it is expected that the move to shut down will begin then. The present price of petroleum in the two fields is about 18 c., and it is expected that the lessening of the output will result in doubling the price.

Nevada County.

Howard & Kemp report having discovered a ledge near French Corral which can be traced for over 3,000 ft. Samples broken off the croppings show free gold in nearly every instance. On the surface the ledge is 18 in. wide. The owners will drive a tunnel into the hill to strike the vein at depth. The ledge is in slate.

Clyde Cole and W. L. Williamson, working in the Giant King mine near Washington, running a tunnel on the vein had got in a distance of five feet when they struck a bad piece of ground. While they were at work driving ahead a cave occurred, catching both men. Williamson was covered with debris to the shoulders, while Cole was pinioned down, a large piece of rock striking him on the leg. Williamson battled bravely to extricate himself and after doing so dug Cole out.

Sinking of the Empire shaft, near Grass Valley, has been resumed.

Placer County.

It is reported that the Pioneer mine, situated near Damascus, has been sold to J. B. Hobson. The Pioneer is one of the oldest quartz mines in the county. During the last few years little work has been done on the property. It is equipped with a 20-stamp mill.

At the Three Stars mine, seven miles west of Auburn, 40 more stamps are to be installed. —— The Eclipse-Morning Star group will start soon. —— The Bullion group, near Auburn, it is reported, is to be taken over by a San Francisco firm. These claims are to the east and north of the Bellevue, which is now producing good shipping and milling ore.——Malmberg's mill is running on custom rock, and there is a good prospect of both the St. Patrick and Pioneer mills being put in running shape. —— The Hathaway is overhauling its machinery awaiting the new machinery to be installed.

San Bernardino County.

The strike made by a man named McClure, 17 miles south of Needles, and another near Vontrigger, along the Santa Fe branch line between Goffs and Manvel, are attracting much attention. Both gold strikes were made in February and made public through the visits of locators to the mills at Needles. The facts became public, when there followed a general scramble, and 1,200 prospectors swarmed into Vontrigger, and nearly as many joined the rush to the McClure district. The ore in the Vontrigger district is iron-stained and free milling. Water is hauled from Lucky Dog Springs, about a mile and a half from the original location. At the McClure camp the ore taken from a shallow hole in the ledge assays $640. The ledge is seven feet wide. At Vontrigger the original discoverers, it is reported, have bonded their claims to a syndicate of Searchlight capitalists for $150,000. In the McClure field the original locator leased his claims to other miners, who paid $2,000 for a long-term lease.

Preliminary work was begun on the 20th inst. by the Santa Fe, on a branch line from Barnwell to Searchlight, Nev., and the work of construction will be started in a few days. The new line will follow the route of the present stage line between the two towns, although in places a considerable distance will intervene. The total length will be 23 miles. It will be completed, the officials say, by August 1st.

Tuolumne County.

The Dead Horse and Lady Washington mines at Carters are to be re-opened. Superintendent P. M. Teague is repairing the boarding-house and bunk-houses on the Lady Washington. On the completion of this work mining operations will be commenced. The company will work these properties through the Lady Washington tunnel.

COLORADO.

Fremont County.

The Dorcas custom ore mill, half a mile north of Florence, was destroyed by fire Monday afternoon. The mill was built six years ago and was valued at $300,000. It was owned by the Dorcas Mining, Milling & Development Co., and treated Cripple Creek ores exclusively.

Ouray County.

A contact has been opened up on the Black Girl, near Ouray, which carries 20 oz. silver. There is also another contact which carries 16 oz. The Black Girl is located less than half a mile north of the Newsboy. One of the contacts is below the lime, the other above it. The contact carrying the higher values is 5 ft. thick. A 50-ton shipment was made a short time ago. Over 400 ft. of the contact has been uncovered and there is from 8,000 to 10,000 tons of ore in sight. Mr. Dupraw will let a contract for the erection of a number of ore-bins for the storage of ore, and work, which had been temporarily suspended, will be commenced with 10 men.

San Juan County.

It is reported at Silverton that the Mountain Queen mine was swept by a snowslide Saturday and all the buildings, including the compressor-house, destroyed. Twenty men escaped without injury. The financial loss is not heavy, as the company had not installed the expensive improvements planned. The Mountain Queen is situated in California gulch, over the ridge from the Sunnyside and Gold Prince properties.

A large party of men left on the 21st on snowshoes for the Shenandoah mine, in Arastra gulch, above Howardsville, to assist in digging for bodies of the twelve miners who were swept to their deaths by a snowslide. Still another party is on its way to Green Mountain mill to search for the body of Foreman D. R Hickey. Considerable alarm is felt for the members of these rescue gangs, as they will be compelled to go over trails where snowslides are frequent.

Slides have been running with dangerous frequency in every direction for the last week, but it was not until Saturday that lives were lost. The property loss has been heavy. Scores of miners and other mine employees have had narrow escapes from being carried away and killed and several persons have been injured. The first slide of importance to come down was early in the morning on King Solomon mountain, which destroyed the boarding house at the Unity tunnel, and Nels Hansen, the cook, had his leg broken. About 75 men are employed at the tunnel, which is part of the Silver Lake property, situated a few miles from Silverton.

The slide continued down the mountain 300 feet and struck the Last Chance workings, a part ot the same property, where five Italians were employed. There it demolished the bunk-house and carried away one of the cabins.

Below the Last Chance the slide struck a little cabin in which was Mrs. Johnson, wife of one of the employees, near the bottom of Arastra gulch, and after tumbling the house upside down several times, landed it safely in the gulch and Mrs. Johnson only received a bad shaking up.

The second slide came down at noon and practically demolished the Green Mountain mill, which has just been installed at a cost of over $300,000.

Summit County.

(Special Correspondence). — A company has been organized in Denver, with the title of the John A. Holmberg Mining & Milling Co., of which State Treasurer John A. Holmberg is one of the principal figures, to work a group comprising 146 acres of mineral ground on McCulloch mountain, six miles southeast of Breckenridge. This property has shown up well in the work done on it, and has made shipments of ore which returned $14 to $18 gold, as well as silver and lead values. The main tunnel is to be driven from the creek level.

The Gold Dust Mines Co. is pushing development in

the main tunnel, beyond the 3,000-ft. point, and the vein is improving.

The Germania mine, under lessees, is shipping gold-silver ore. The shipments are going through the local sampling works.

The Rothschild tunnel at Argentine is now in 3,500 ft. and Manager Thomas Webb is daily expecting to cut the Traffic vein, one of the two large high-grade veins for which this tunnel was started. The other vein is the Rothschild, and should be met within 100 ft. after the Traffic is cut. Mr. Webb intends to drift along the vein which was cut at the 2,850-ft. mark and ship from it. Part of this orebody gives high assays in silver.

The Stoughton Mining & Milling Co., a Wisconsin corporation, operating the Carrie mine on Wise mountain, intends to enlarge its cyanide plant as soon as the weather will permit. In the raise from their main level there is a 4-ft. ledge of pay ore. A new tunnel will be started to the vein from the mill level, and to cut all the known veins at depth and save hauling to the mill.

Breckenridge, March 17.

Teller County.

A five years' lease, with bond of $300,000, has been granted by the directorate of the Index Mining & Milling Co. on its estate on Gold hill, of 27 acres, to Dr. Hereford, Phil Knowlton and Captain Cavanagh. The lease, it is learned, will be transferred to the Ætna Investment & Development Co., a corporation to be organized.——W. P. Sellors, who secured a three years' lease on the Yellow Bird, on the west slope of Gold hill two weeks ago, and a few days after struck a three-foot vein of five-ounce ore at the 150-ft. level south of the shaft, is constructing a new shaft-house and erecting ore-bins. A steam hoisting-plant has been ordered, and as soon as the machinery is installed shipments will follow.

IDAHO.

Owyhee County.

Work has been suspended on the Trade Dollar Extension, it being impossible to get timber and lagging to the mine owing to the condition of the roads. C. W. Hill, who has been east all winter in the interest of the Stormy Hill group of mining claims on War Eagle mountain, is expected to resume work on the property shortly.——C. E. Kingsley, who has the contract for running 300 ft. of tunnel on the Banner property, measured 80 ft. for the month, leaving 50 ft. to go on his contract.

H. M. Stevens, of the Rich Gulch mines, says they are getting their bins filled with fine-looking ore—some of it rich in silver—but that they are having difficulty in getting timbers and the wet ground they are working in requires considerable of it.

Shoshone County.

Superintendent Davis of the Gold Ridge Mining Co., reports assays from the recent strike in the 80-ft. shaft on the company's claims, six miles east of the head of navigation on the St. Joe river, to show 12% lead, 5.4 oz. silver, .29 oz. gold; total $21.24; a second assay, 2.2 oz. silver, 3.08 oz. gold, total $65.02. The last assay was taken from the bottom of the shaft, six feet into the ledge just struck. Mr. Davis says that by the 1st of April he will be able to take in hoisting machinery and blowers. A new boarding-house is being built and will be completed by the time the machinery can be taken in.

MONTANA.

Beaverhead County.

The Calumet & Montana Mining Co., composed of Michigan and Montana men, has taken over six full claims in this county and intends to develop them. There are two tunnels on the property, one of which is 125 ft. long and the other 160 ft. They are 60 ft. apart. It is claimed there are five feet of copper ore in the upper one, and that a shipment to Salt Lake gave $66 in gold, $4 in silver and 18% copper. The district in which the property is situated is known as the Copper Queen.

Granite County.

Manager G. H. Savage of the Milwaukee Gold Extraction Co., in Red Lion district, has returned from a month's visit to Chicago and Milwaukee, and says work in the mines, which was suspended in January, is to be resumed. The company had decided to install machine drills, and work will be commenced in a tunnel 300 ft. from the mill to open the Hannah mine at a depth of 700 ft. Machinery, including power-drills, pipe, etc., is en route and will arrive in about a week. A compressor is already installed at the mill and this is to be employed in operating the drills in the tunnel. The water supply of the mill has been frozen up since early in the winter, but a spring near will furnish sufficient water for the boilers to run the air compressor. It will be several months before the mill can be started. The Hannah vein is 60 ft. wide, and beside gold carries 40% iron and traces of copper. Down nearer the water level the copper becomes more pronounced. During the coming summer Mr. Savage proposes to install a hoist and pumps and sink several hundred feet on the lead.

Silver Bow County.

The Pittsburg & Montana Copper shipped a carload of copper Saturday, making the second shipment this month, making nearly 50 tons. It is raising all the ore the plant can handle and keeping a good supply on hand.——A vein of silver-gold ore has been struck on the 500 ft. level of the Blackrock mine and shipments made from it. The ore contains some copper. The shaft on this property reached the 500 mark a short time ago. A. P. Peake of Valley City, N. D., is president of the company.

The Butte & Bacorn Co. developing ground at Horseshoe bend, north of Meaderville, is making good progress. All of the shafts, four in number, are about 65 ft. deep, and two will be sunk to an indefinite depth.

It is expected that the converters at the Butte reduction works will be ready for business between April 15 and May 1. They a e practically in place now, but some other work will have to be done before they can be used. They are taking the place of the blister copper furnaces which were installed as an experiment about three years ago.

NEVADA.

Esmeralda County.

The Contact Gold Mining Co. has been formed by J. H. Mitchell, J. H. Miller, G. S. Green, J. E. Adams, Eugene Ferretta, H. F. Launtz, A. Miller and G. P. Geyer to operate the mines of this company, adjoining the Wild & Pardini ground in North cañon, seven miles south of Hawthorne. The Contact company owns eight claims in one group. There are several ledges exposed which pan free gold, and assays run from $5 to $50 on surface rock. The directors of the company are J. H. Mitchell, J. S. Calvert, J. H. Miller, A. Miller and G. S. Green.

Gilbert Briggs is interested with others in a group of claims in Huntoon Valley, 40 miles south of Hawthorne. The country is cappedwith porphyry, which makes prospecting difficult. The ledges are strong, some of them run in as high as $150 per ton. The samples shown are honeycombed quartz, showing galena, which runs high in silver. The gold values are principally in iron oxide. A company of Oakland capitalists is opening properties in Huntoon, and the Lee brothers are taking out specimen ore.——L. Bacigalupi has struck a 4-ft. vein of $30 ore on the Millsap claim in North cañon. This mine is now the property of DeChambeau, Dondero and Bacigalupi.

Humboldt County.

Thirty-five miles northwest of Lovelocks is a mining district known as the Seven Troughs. This section has lately attracted attention owing to good assays and pannings from claims owned by J. Therien, W. Stautts, A. Borland and F. Crumpacker. It had not been prospected because it was a porphyry formation and had little showing of the kind of quartz supposed to carry values. The discoveries in the southern part of the State set the prospectors to looking for gold in porphyry, and some who had been to the southern camps remembered the Seven Troughs district to be similar and went there to search for the yellow metal. W. Stautts and J. Bishop prospected the cañon, by panning, from its mouth up to the troughs, getting colors up to that point but none above. At the troughs a big porphyry dike crosses the cañon and careful prospecting showed it to contain rock assaying from $12 to $50.

Lincoln County.

(Special Correspondence).—The Cyrus Noble mine is still sinking in ore. The management is sinking to a depth of 1,000 ft. Four shifts are employed. The mill is running on $80 rock and when the water pipes being laid are all connected three shifts per day will be put on. A shipment of bullion will be made from the Cyrus Noble in a few days and a dividend will be paid in April. The electric plant is installed and wiring is progressing rapidly.

The recent investment of Eastern capital in the Parallel has resulted in a renewal of activity in sinking a 200-ft. shaft from the 300-ft. level and several hundred feet of drifting and crosscutting. It is one of the best located mines in the belt. Lack of capital had rendered anything but desultory work impossible heretofore. A large force will be put to work and the mine thoroughly developed. Two shifts will be employed at first. Robert Lanka is consulting engineer. The Parallel is situated immediately north of the Cyrus Noble mine, west of the Santa Fe, and south of the Big Six and Southern Nevada groups. The mine has produced ore that ran several hundred dollars per ton.

Owing to the unexpected flow of water on the Black Hawk of Le Roy Mining Co., work has been suspended until the installation of a pump. The shaft is down 275 ft. and drifting will be started above the water level.——The 10-h.p. hoist of the Treasurer Co. is now in operation and the shaft is to be sunk to the 250-ft. level. At present they are down 35 ft. in ledge matter, and good pannings are obtainable anywhere. This property is situated on the townsite, and the strike was made on the corner of Main and Haviland streets.——The Mountain group is still absorbing all the interest in El Dorado district, as the work of sacking ore continues on the Lela B. of that property. The rich streak is two and one-half feet wide. It was encountered in running a 15-ft. open crosscut.

The El Dorado-Nevada is proving the width of the ledge on the Silver Legion. It has been crosscut nine feet without finding the foot-wall. A sulphide ore has been opened up at 150 ft. that is richer than the rock found at the 100-ft. cut.

The Nevada Consolidated Mines, Ltd., have purchased the McGhan & McLaughlin group, consisting of 20 claims, in the Sunrise district, for $250,000. George P. Spittall, of Philadelphia, is at the head of the company, Marius de Brubant, general manager of the Salt Lake route, is a director, and represents a syndicate of Montana capitalists who have invaded southern Nevada in search of promising mines. Machinery is on the way to the property, and when it arrives three shifts will be put to work, supplementing the force of 45 men now employed. Contracts have been let for sinking shafts 350 ft. each.—— Water has been struck on the Boulder at a depth of 175 ft. and pumps are to be installed. Drifts have been run at 65 and 165 ft. and a body of free-milling ore has been found. Sinking will be resumed to the 400-ft. level as soon as the shafts have been relieved of the water.

Searchlight, March 17.

Storey County.

A new rock-breaker has been installed at the head of the chutes leading to the C. & C. ore-house. All of the second-grade ore hereafter sent to the Kinkead mill for treatment from the Consolidated Virginia and Ophir will be run through this breaker. A rock-breaker has been used for years in crushing the coarser first-grade ore before dumping it into the bins, but does not pulverize as it is reduced by the new breaker, and unless the entire bulk of ore as it comes from the mines is well pulverized, it is impossible to obtain a reliable average of its assay value, as the coarser rock may or may not carry the highest percentages in gold and silver. The new breaker will be operated by electric power.

NEW MEXICO.

Santa Fe County

At Cerrillos, the new concentrator on the Cash Entry is about ready for active operations. It will have a capacity of 50 tons daily and will be run day and night if the ore supply holds out. The company which owns this concentrator has recently purchased a number of mining claims in Hungry Gulch and other properties in the district, and the manager is of the opinion that there is plenty of ore in the vicinity to supply the concentrator.

D. C. Allard, who is mining on 70 acres of land east of Santa Fe, within the Santa Fe Land Grant, which he purchased from the city of Santa Fe four years ago, has recently struck a vein bearing zinc, gold and silver. The ledge is 40 ft. in length and 10 ft. in width as far as exposed. The assays show $60 zinc, $10 gold and $5 silver. Mr. Benson, who represents David H. Moffat, of Denver, has made his report, and negotiations for the purchase of this property are in progress. The Gibson Development Co. of Santa Fe has claims west of the property owned by Mr. Allard and an extension of the ledge above referred to was found at a depth of 60 ft. on their property. Last year a small force worked several months on this development. This spring this company will continue operations, as soon as the weather settles. The Moffat syndicate is looking for zinc mining property in New Mexico. Mr. Allard and associates have discovered another body of zinc ore in the Tesuque Box cañon, six miles north of Santa Fe. Development work on these claims has been done.

At the Junction, the new engine is ready for work. Construction of the new steel frame at the Junction has begun. On the 900 and the 1,000 ft. levels development is encouraging, and as soon as the new head-frame is ready, sinking will be resumed. A large block of ore has been exposed in the Junction drifts. On the 900 drift two ore bodies have been cut. The first in close proximity to the shaft on the north. This was passed through and at 71 ft. from the shaft, in the same direction, the second body was encountered lying almost horizontal with a dip to the north. The drift cut through this orebody for a distance of 40 ft. On the 1,000 a drift is being run in the same direction to intercept this orebody. On the 900 a second drift is being driven east in leached material with favorable indications.

At the Briggs shaft a drift is being driven from the winze which is 175 ft. below the 910 ft. level, 600 ft. from the shaft in a southeasterly direction. An orebody was encountered in a drift from this winze several weeks ago 100 ft. below the 910 level of the shaft. At the bottom level of the Briggs shaft a drift has been started north from which two crosscuts have been run, one in the direction of the Hoatson and another toward the Junction. This territory is to be developed. At the Irish Mag shipment of ore continues to the smelters as usual, and the production for March will be in excess of the February production. Shipments from L. S. & P. and P. & D. have been gradually increased during this month. At the Oliver the principal development work has been confined to a drift south on the Buckeye claim from the 1,150 level. This drift has encountered a large body of fine ore.

SOUTH DAKOTA.

Lawrence County.

The Horseshoe Co., at Terry, continues shipments of smelting ores to outside plants, and, pending the construction of the new mill at Pluma, good production is being maintained at 100 tons a day, nearly all of which comes from the Ben Hur mine. Plans for the remodeling of the Kildonan mill, at Pluma, are completed, and construction will commence in a few days.

The Homestake Co. has presented a cabinet of specimens of characteristic ores to the State School of Mines at Rapid City. The specimens include samples from every level from the surface down to the 1,400-ft. workings. They are set in cement molds, and include porphyry, quartz, talc, and all the gold-bearing minerals of the mine.

Superintendent O. N. Brown of the Spearfish Co. says that during February the mill handled 5,949 tons in 26½ days. Working at this capacity, the Spearfish is enabled to handle a low grade of ore at a slight margin of profit. At present the company is exploring the Metallic Streak ground, where high-grade ore was mined in the early history of the camp. A tunnel is being run to develop a section of virgin ground in this neighborhood. Chances are good for the discovery of pay ore in this vicinity. The company is preparing to explore the deeper formations next summer by the aid of a diamond drill. Several holes will be sunk to quartzite—a distance of probably 600 to 700 ft.—and the ore horizon explored.

Pennington County.

(Special Correspondence).—C. O. Bartlett of Cleveland, Ohio, has taken up the option on the Clara Belle Mining Co.'s property, Oreville, the control passing to him and his associates.

About $30,000 have been spent on this property during the last nine months in building new houses, putting in a saw mill, a new shaft-house, new 10-stamp mill, compressor and drills, boilers and engines, sinking the shaft, driving tunnels, etc. Samples of ore were sent to Fueller, of Denver, and running tests made on ore taken at a depth of 250 ft., which yielded $44 per ton, 75% of which was saved on the plates, and the balance up to 94% by cyanide.

The small 2-stamp mill has been running since October, and will continue to run until the 10-stamp mill is finished about May 1. The small mill is turning out over $100 daily from the plates. The tailings are being stored for future treatment in the new mill. A new shaft will be sunk to tap the orebody at a depth of 500 ft. At a depth of 250 ft. the ore-shoot was 27 ft. long and from three to five ft. thick. At 300 ft. it had increased to over 100 ft. in length and from four to eight ft. thick and richer in free gold.

There are good reasons to believe that this property will prove to be one of the best mines of the Black Hill-.

It consists of about 200 acres, one and one-half miles from Oreville, with plenty of good timber and water.

Oreville, March 17.

Men are employed at the National smelter, at Rapid, on repairs and other work incidental to the blowing in at an early date. With the completion of the M. R. & N. W. road, which will give connections with the Burlington at Mystic, and a connection with the mines of the Northern Hills, the mill will be started. It is planned to operate one furnace at first, and as soon as business warrants the capacity will be increased. The plant will treat 100 tons of ore daily. Arrangements have been made for deliveries of coke, limestone and pyritic flux—the latter coming from Colorado. Several of the mines of the Northern Hills will ship a large portion of their ores to the plant.

WASHINGTON.

Ferry County.

(Special Correspondence).—A body of iron sulphide has been encountered above the No. 2 tunnel level of the Copper Key mine. The raise, 4 by 6 ft., is all in ore, the assays showing an ounce of gold, a little silver and a small quantity of copper per ton. The strike is of importance on account of the excess of iron contained. The working force is being increased, putting the mine in shape for stoping, in view of railroad transportation direct from the mine. On the main (No. 2) tunnel level a drift is being driven to get under surface orebodies, from which a hundred carloads have been sent to the smelters. The Oversight group adjoins the Copper Key on the southwest and is being developed. The Anonymous group adjoins on the northeast.

The Richey Mining & Development Co., of Pullman, owns the Frisco Fraction group on Iron mountain, eight miles east of Republic. A tunnel is being driven under contract. It is expected to tap the vein 110 ft. from the portal. The ore assays six per cent copper, with gold and silver to a total value of $100 per ton in the best ore.

Ore is being shipped from the Ben Hur mine as fast as the smelters at Trail and Greenwood, B. C., will take it.

The Pearl Consolidated Mining Co. has started to raise and sink on pay-ore from the 190 level of the Lone Pine. All of the second-class ore on the dump has been shipped to the smelter.

The shipments of silicious ore from the Quilp amount to a carload a day. The mine employs fifteen men.

Republic, March 17.

Township 37 and 38 north, range 32 east, Willamette meridian, to be opened for filing April 16, are situated, relatively, north of and adjoining Republic, and are bounded on the west by the east boundary line of Okanogan county. The Quilp, the Morning Glory, the Lone Pine, the Pearl and the Surprise group, the San Poil, the Blacktail, the Ben Hur, the North San Poil, the Trade Dollar, the Knob Hill, the Mountain Lion and other leading mines of this district are situated in these townships, as also are the Empire and a part of Sheridan camp.

Okanogan County.

(Special Correspondence).—The Copper World Extension mine, on Palmer mountain, is developing iron sulphide ore in the 200 level. The south crosscut has crossed several small veins of ore and one orebody 23 ft. wide. The ore carries gold, silver, and copper.

The Grand View Mining Co. has tested its new electrical machinery, the Riblet aerial tramway having previously been in operation and the bins at the lower terminal filled with ore. The machinery ran satisfactorily. Only a small force of miners has been employed. Several weeks may elapse before the stamps begin dropping and the ore reserve is large enough to ensure a continuous run. It is reported that the Copper World mine will soon be in operation.

The latest development at the Phil Sheridan mine, of Sheridan, is a new body of ore encountered in the south drift on the vein, on No. 1 tunnel level. The ore is of good quality. The old stope has been extended in length and height above the tunnel. Ore is accumulating at Lynch's siding, on the railway, for shipment to the smelter.

An open cut on the Stemwinder, 75 ft. from the Kismet of the Phil Sheridan group, has developed an orebody thirty feet deep. This is the second strike made on the Stemwinder this season.

The Viola Gold and Copper Mining Co. has a group of claims on Eneas mountain, in Galena district, 17 miles south of Loomis. They cover 140 acres on the south slope of the mountain, and carry veins of gold, silver, copper and lead ores. Some of the lead ore is rich in silver, and the gold and copper values are good. Joseph Coleman, the local manager, recently stated in Republic, that the company expects shortly to install machinery.

The contract for driving 100 ft. on the No. 2 and 100 ft. on the No. 3 tunnel level of the Bodie mine, at Bodie, has been completed and men have since gone to work on optional contract on the No. 2 level.

Loomis, March 17.

Stevens County.

(Special Correspondence).—The Hibernia Mining Co., in Pierre Lake district, has been open cutting on two veins, one of them 24 ft. and the other about 100 ft. wide. The former is low grade in gold but some of it paying to ship. The latter is a contact between porphyry and rhyolite. Three shafts, respectively 22, 35 and 60 ft. deep, have been sunk, and the latter timbered to a depth of 40 feet.

There is considerable activity in the mines of this county, although the Old Dominion mine has been idle for a year and a half. The Copper King, in Chewelah district, has been shipping good copper-gold ore lately. Several properties have been bonded, the main incentive being the shipment of gold ore, which in the past year amounted to $180,000 from the First Thought mine, twelve miles from Orient, in Pierre Lake district.

The marble industry in Stevens county is increasing. The Standard Marble and Onyx Co. is making preparation for large output from its quarries, five miles east of Colville. The Crystal Marble Co. is operating quarries west of Addie. The Kettle River Marble Co. is operating at Barstow, and for the last six months the Jefferson Marble Co. has been opening up its quarry. Across the river, in Ferry county, there is a long stretch of country that will probably be operated, and within five miles of Danville marble is abundant, but still in the hands of small owners.

Colville, March 17.

WYOMING.

Carbon County.

The Stemp Spring Coal & Power Co. is preparing to erect a 250-ton smelter, including a matting furnace and concentrating plant, at Dillon. The plant will be erected on the south side of the grounds of the Jack Pot Mining & Milling Co. and the Anchoria Copper Mining Co., within reach of every mine and prospect of the Battle Lake Mining District. Within short haul of the smelter, hundreds of tons of copper ore lie on the dumps of mine and prospect. The Pluto, Independence, Batchelder, Congo Itmay, Azurite, Jack Pot, Anchoria, Oshkosh-Wyoming, Judith, Toronto Girl, and other properties in the producing stage of development, are awaiting the smelter. Contracts are now in possession of the Smelter Co. sufficient to guarantee a steady run to its fullest capacity for months.

Near the site of the smelter a water power, owned by the Jack Pot Mining & Milling Co., has been leased for twenty years by the Smelter Co. With this water a power plant, to be erected at the company's coal mines, will furnish light and power to the various mines of the district.

FOREIGN.

CANADA.

The Geological Survey of Canada reports the production of metallic substances in the Dominion during 1905 as follows:

Product.	Quantity.	Value.
METALLIC.		
Copper ..... Lb	47,597,502	$7,420,451
Gold, Yukon $8,327,200		
Gold, all other 6,159,633		
		14,486,833
Iron ore (exports, estimated) ..... Tons	116,779	125,119
Pig iron from Canadian ore ..... Tons	70,554	1,047,860
Lead ..... Lb	55,961,000	2,634,084
Nickel ..... Lb	18,876,315	7,550,526
Silver ..... Oz	5,974,875	3,605,957
Cobalt	.....	100,000
Other metallic products, including zinc	.....	180,000
Total metallic	.....	$37,150,830

The production of non-metallic products is officially given as follows:

Product.	Quantity.	Value.
Asbestos ..... Short tons	50,670	1,486,359
Asbestic ..... Short tons	17,594	16,900
Chromite ..... Short tons	8,575	93,301
Coal ..... Short tons	8,775,933	17,558,615
Corundum ..... Short tons	1,644	149,153
Felspar ..... Short tons	11,700	23,400
Graphite ..... Short tons	541	17,032
Grindstones ..... Short tons	5,172	57,200
Gypsum ..... Short tons	435,789	781,543
Limestone for flux in iron furnaces. Short tons	341,614	258,759
Manganese ore (exports) ..... Short tons	22	1,720
Mica ..... Short tons	.....	168,043
Mineral pigments—		
Barytes ..... Short tons	3,360	7,500
Ochres ..... Short tons	5,105	34,675
Mineral water	.....	100,000
Natural gas	.....	314,249
Petroleum ..... Bbl	634,095	849,687
Phosphate ..... Tons	1,300	8,425
Pyrites ..... Tons	32,744	123,574
Salt ..... Tons	45,370	310,858
Talc ..... Tons	500	1,800
Tripolite ..... Tons	200	3,600

BRITISH COLUMBIA.

Vancouver Island.

During February the Tyee smelter ran 13 days and treated 2,224 tons of Tyee ore, giving a return, after deduction of freight and refining charges, of $34,402.

Yale District.

For two weeks there have been reports of strikes in Le Roi mine. It is reported that the strikes are the most important made in Le Roi in the past eight years. What appears to be the most important strike, was made west of the Josie dike. In Le Roi territory, the section west of Josie dike, which comprises lengthwise about one-half of all the territory of Le Roi, there has been found a body of high-grade ore, which has been drifted on for some distance. The drift is five by seven feet, and is in ore for all the way. Its width is not yet known, as it has not been crosscut. The second strike in point of importance was made on the 600-ft. level, where an ore-shoot of 20 ft. in width has been found. This shoot is opened 50 ft. in length. The ore in this shoot is of good grade. The third strike is reported to be on the 1,050-ft. level. This is a narrow shoot of high-grade ore. On the 1,650-ft. level in a crosscut north from the winze ore has been located which has been crosscut for 20 ft. A fifth strike has been made near the surface of what is supposed to be a portion of what is known as the Peyton shoot, at one time the richest in the mine. Andrew Larson, the superintendent of Le Roi, conceived the idea of running a crosscut on the 800-ft. level across the 80 ft. of the Josie dike, who found the shoot in the new territory.

Eric Stevenson and associates have leased the O. K., at Rossland, and during the week put 30 tons of ore through the mill. The result was a gold bar worth $300 and two tons of concentrate worth $100 a ton.——Following are the shipments for the week: Centre Star, 3,660 tons; Le Roi, 2,430; Le Roi No. 2, 720; O. K. (crushed), 30. Total for the week, 6,840 tons, and for the year to date, 66,255 tons.

Shipments from Boundary mines for the week ending March 17 were as follows: Granby mines to Granby smelter, 17,014 tons; Mother Lode to B. C. copper smelter, 3,172; Brooklyn Stemwinder to Dominion smelter, 2,706; Rawhide to Dominion smelter, 510; Oro Denoro to Granby smelter, 756. Total for week, 24,108 tons; total for year, 264,397 tons. The Boundary smelters treated as follows: Granby smelter, 18,236 tons; B. C. Copper Co. smelter, 4,353; Dominion Copper Co. smelter, 3,336. Total ore treatment for week, 25,920 tons; total for year, 273,313 tons.

Total ore shipments for the past week from all mines in the Yale-Kootenai district amounted to 31,883 tons, and for the year to date 360,083 tons. Slocan-Kootenay shipments were small, owing to the late blizzard, but totaled 1,391 tons, and for the year to date 22,052 tons. The principal Slocan-Kootenay shippers were the St. Eugene, 549 tons; Sullivan, 500; Hunter, 180; Sunshine, 40; other mines, 122. Three new shippers—the Majestic, Molly Hughes and Sunshine—were added to the list, making a total of 70 shipping mines this year over the whole district.

Owing to the severe frost of the past week, J. W. Jones, who has the contract for building the Great Northern spur into the Belcher mine, on the reservation near Curfew, has had to discontinue work, but had the grading sufficiently advanced to enable the management of the Belcher to unload several carloads of rolling stock for the mine, including engines, ore-cars, etc. The Belcher is working about forty men and will increase that number as soon as this railroad spur is completed, in about a month's time.

MEXICO.

Chihuahua.

(Special Correspondence). — Geo. M. Ryall, accompanied by Forbes Rickard, and a party of six other Americans, and escorted by 18 rurales with two officers, left La Colorada on the 16th inst. for La Dura and Barranca, in the Yaqui river region. Indian depredations continue and Yaqui raids are more frequent than ever. It is foolhardy to go into the Yaqui country without an escort. The party referred to above expect to return to La Colorada in 10 to 12 days, or possibly later, should they decide to go on to La Bufa. Geo. M. Ryall has two concessions, bounded by the Rio Tecoripa on the west and the Rio Yaqui on the east. They cover an area of nearly 2,000,000 acres and take in much valuable mining property. The Cananea, Yaqui River & Pacific Railroad, building under the Southern Pacific Railroad, with Col. Epps Randolph president, is laying rails to La Bufa, under forfeit to complete this branch to La Trinidad this year. The railroad will traverse Mr. Ryall's concessions for more than 50 miles and tap the anthracite field at Barranca. With the conveniences afforded by this road, and the cheap fuel, it is thought the mineral territory, much of which was worked by los antiguas, will be rapidly developed, as it will then be much easier to work out the several metallurgical problems now involved in the handling and treatment of the silver-copper ores of this district.

La Colorada, March 16.

H. N. Jackson, manager of the Santa Eulalia Exploration Co., is completing the new hoisting plant at the company's mines in Santa Eulalia.

NOVA SCOTIA.

The gold mine recently started at Middlefield, 15 miles from Liverpool, caved on the morning of the 15th inst., burying four men. The body of one man has been recovered, but the work of unearthing the others had to be abandoned, as the pit started to cave in again, and 50 tons of earth covers the other three.

PHILIPPINE ISLANDS.

H. D. McCaskey, chief of the division of mines at Manila, says there is much mining activity in the Aroroy district of Masbate. The Philippine Mining Co. is operating a dredge on the Lanan river, and Manager F. Kimbal is in the United States to get two more dredges to be operated on the same river. On the Guinobatan river, the Oriental and Masbate Co. is dredging. The Eastern Mining Co. has made a number of trial runs with its 5-stamp mill on its claim in that district. The Oriental-Masbate Mining Co. has purchased a number of claims in the same section and has put in a 10-stamp mill, which was originally for its mines at Benguet. The Coghran Mining Co., which is operating on the Upper Lanan river has ordered a 10-stamp mill.

Books Received.

'Standard Telephone Wiring' is the title of a neat handbook, with flexible covers. It is for the use of telephone men, and contains diagrams of circuits for straight lines, party lines, plans, sub-stations, and various other arrangements. A useful book for the practical man and the young engineer. Sent by the MINING AND SCIENTIFIC PRESS upon receipt of price —$1. McGraw Publishing Company, New York.

'The Wiring Handbook,' with complete labor-saving tables and a digest of the Underwriters' rules. This book, by C. P. Poole, is intended for the use of wiremen who are obliged to lay out their own work, and for engineers who make up wiring plans and specifications. As the book contains rudimentary instructions it will be valuable to the practical lineman and young electrician. Illustrated by numerous drawings. Sent upon receipt of price—$1, net—by MINING AND SCIENTIFIC PRESS. McGraw Publishing Co., New York.

'The Elements of Mining Geology and Metallurgy,' by G. W. Miller, a practical man, has been added to the list of books for the use of prospectors and investors in mines who desire information in language that can be understood without first acquiring a technical education. The work embodies many examples of actual conditions and working methods, and cannot fail to be of value to the novice. It will be sent by the MINING AND SCIENTIFIC PRESS upon receipt of the price, post-paid, $3.50. Published by the Daily Mining Record of Denver, Colorado.

A treatise on 'Producer Gas and Gas Producers,' by Samuel S. Wyer, is the latest contribution on this inter-

esting subject, which is of growing importance. The work reviews the fundamental physical and chemical laws concerning the subject, defines gases and the status of producer gas, its manufacture, use and efficiency. The book treats the subject thoroughly and completely. It is profusely illustrated. Sent by the MINING AND SCIENTIFIC PRESS. Price, $4. The Engineering and Mining Journal, publishers, New York.

Personal.

C. A. MOREING is in Western Australia.

ANTON EILERS is at Aguascalientes, Mexico.

J. NORTON GRIFFITHS is in southwest Africa.

T. M. RIORDON is at the Bully Hill mine, California.

E. C. VOORHIES is in San Francisco from Sutter Creek.

J. H. SLATTERY, of Silverton, Colo., is at the St. Francis.

S. J. SPEAK leaves London shortly to proceed to Sumatra.

W. H. RADFORD has returned from Clear Creek, Colorado.

JOHN B. FARISH has left San Francisco on his return to Denver.

BEN. S. REVETT is on his way back from Colombia to New York.

WILLIAM A. AKERS is visiting San Francisco from Los Angeles.

J. H. CURLE sailed for Japan on the *Korea*, which left on March 22.

JOHN ROSS, JR., has returned to Sutter Creek from San Francisco.

ERNEST A. WILTSEE has returned from Mexico and is now in Nevada.

C. M. YEOMANS returned from Australia on the *Sierra*, arriving March 19.

GEORGE KISLINGBURY is examining copper mines at Yerington, Nevada.

JOHN HAYS HAMMOND has been ill at the St. Francis Hotel, but he is better.

C. E. KNOX, president of the Montana-Tonopah mine, has returned to Tonopah.

H. C. WILMOT has charge of unwatering the Altoona shaft near Butte, Montana.

REGIS CHAUVENET has returned to Denver from a professional trip in Arizona.

JOHN T. OVERBURY, of the Mayflower-Bullfrog mine, has returned from Honolulu.

F. F. THOMAS, manager of the Gwin mine, has returned from Arizona to San Francisco.

H. A. LEE, of Denver, is in San Francisco, on his return from Chihuahua, Mexico.

J. TROWBRIDGE BAILEY has returned to New York; he will proceed shortly to Brazil.

PALMER CARTER is returning from South Africa for a visit home, at Washington, D. C.

THOS. J. MURPHY has been appointed manager of El Doctor mine, in Queretaro, Mexico.

PERCY MORGANS, of Western Australia, has arrived in San Francisco on his way to Mexico.

E. OSCAR HART, of New York, is not connected with WALTER SCOTT. This is stated by request.

OSCAR ROHN, manager of the Pittsburg Montana Mining Co., at Butte, is ill with typhoid fever.

J. J. CRAWFORD has returned to San Francisco from the Gwin mine in Calaveras county, California.

C. S. HERZIG has left Melbourne, on promotion to the London office of Bewick, Moreing & Company.

KARL EILERS was with the Guggenheim party at the St. Francis hotel. He has returned to Salt Lake.

F. H. JACKSON, of Broken Hill, New South Wales, arrived on the *Sierra*. He goes to Mexico shortly.

F. J. BOOTH has resigned as superintendent of the Kings Quicksilver Mining Co. and is in San Francisco.

MARK L. REQUA is leaving for New York in connection with the reorganization of the Nevada Consolidated Copper Company.

NEWTON W. EMMENS is on his way from Pittsburg to Sonora, Mexico. Subsequently he will go to the new goldfields in Nevada.

ROBERT A. KINZIE, superintendent of the Alaska-Treadwell mine, has returned to Douglas Island, after a short holiday at Monterey.

ROBERT C. GEMMELL, general superintendent of the Utah Copper Co., is making an examination of the Balaklala copper mine at Kennett, California.

A. CHESTER BEATTY is at the Silver King mine at Park City, Utah, which was recently examined by engineers in the employ of THOMAS F. COLE.

J. P. SIDWELL, president, and M. D. SHIPMAN, treasurer the Atlas Gold Mining Co., Ouray, Colo., have returned to their homes in Chicago and De Kalb, Ill., respectively.

WILLIAM G. SHARP, former manager of the Utah Fuel Company, but more recently general manager of the Somerset and Fairmont Coal Companies, has been elected president of the United States Smelting, Refining & Mining Company.

METALS.

SILVER.—Per oz., Troy: New York, (by wire), bar silver, 65¼c. per fine ounce; San Francisco, 65¼c.; London, 30½d. (standard ounce, 925 fine); Mexican dollars, 50@51c., San Francisco; 50c., New York.

COPPER.—New York (by wire, average for week ending March 22), Lake, 18.55@18.75c; Electrolytic, 18.25@18.50 Casting, 17.75@18.25c. per pound. Mill copper plates, $21; bars, 21@24c. London: £81 5s. spot per ton.

LEAD.—New York (by wire, average for week ending March 22), $5.35 per 100 lb; San Francisco, pig, 5.70@6.60c. per lb.; pipe 7¾c.; sheet, 8¾@9¾c.; London: £16 1s. 3d. ℔ long ton.

SPELTER.—New York (by wire, average for week ending March 22), $6.17@6.22 ℔ 100 lb.; London, £24 15s. ℔ ton; San Francisco, ton lots, 7c.; 100-lb lots, 7¾c.

TIN.—New York, pig, $37.00@37.25; bar tin, ℔ lb., 42½c.; pig, 39c. London, £167 12s. 6d.

PLATINUM.—San Francisco, crude, $18.50 ℔ oz.; New York, ingot, nominal, $20@25 ℔ Troy oz. Platinum ware, 75@$1.00 ℔ gram.

QUICKSILVER.—New York, $40.00@$41.50, large lots; London, £7 7s 6d.; San Francisco, local, $39.00 ℔ flask of 75 lbs.

NICKEL.—New York, 48@60c ℔ lb.; ton lots, 40@47c.

ZINC.—Metallic, chemically pure, ℔ lb., 50c.; dust, ℔ lb., 10c.; sulphate, ℔ lb., 4c.

BABBITT METAL.—San Francisco, No. 1, 10½c.; No. 2, 8c.; No. 3, 7½c.; extra, 17½c.; genuine, 32½c.; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 23.50c; San Francisco, Plumbers', 100-lb. lots 19.75c.

ALUMINUM.—No. 1, 99%, small lots, 35@38c. ℔ lb.; 100 lbs., 35c.; 1000 lbs., 34c.; ton lots and over, 33c., Pittsburg. No. 2, 90%, small lots, 34c.; ton lots and over, 31c, Pittsburg.

GENERAL SUPPLIES.

ANTIMONY.—New York, per quality, 16c@17c; San Francisco, 1000-lb. lots, 16c; 300@500-lbs. 12c, 100-lb. lbs. 12c; 100-lbs lots, 13c.

BONE ASH.—Extra No. 1, 6c ℔ lb; No. 1, 5c½.

BORAX.—Concentrated, 9½c ℔ lb; powdered, 10c; fused, 25c; crystal, refined, 8c.

CANDLES.—Standard Oil Co.—Electric light, 16 oz., 11c; 14 oz., 9½c; 12 oz., 8½c; 14 oz., 7½c; Hotel, 12 oz., 9c; Granite (mining), 16 oz., 11½@11¾c; 14 oz., 10@10½c; 12 oz., 9½@9¾c; 10 oz., 8½c; Paraffines, White, 1s, 2s, 4s, 6s, 10½c; 12s, 11c; colored, 1c higher; Radiant Paraffines, 4s, 6s, 14 oz., 9½@9¾c; 10 oz., 7¾c.

CAPS.—3x, $5.50@6 per 1000; 4x, $6.50@7; 5x, $8@8.50; Lion, $9@9.50, in lots not less than 1000.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 23@24c ℔ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 3@3½c ℔ lb.; caustic soda, in drums, 3@3¾c ℔ lb.; Cal. s. soda, bbls., $1.10@1.20 ℔ 100 lbs.; sks., 90c@$1.00; chlorate of potash, 12@13c; nitrate of potash, 6¾@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2¼@2½c; flour sulphur, French, 2¾@—c; alum, $2.00@2.25; California refined, 1¾@2c; sulphide of iron, 8c ℔ lb.; copper sulphate, 6½@7c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66% B, 1¾@2c ℔ lb.; nitric acid, carboys, 8c ℔ lb.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1**, 50%, carload lots, 11¾c; less than one ton, 13¾c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2**, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

COAL.—San Francisco, coast, yard prices to dealers: Wellington, $7.50; Seattle, $6.50; Coos Bay, $5.50; Cargo lot, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $14.00; Cannel, $8.50; Rock Springs, $8.50, long ton; Colorado Anthracite, $14.00. Coke, $11.50 per ton in bulk, $13.00 in sacks; Sunnyside, $8.50, long ton.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $18.35; gray forge, $17.85; San Francisco, bar, 3½c. ℔ lb., 3¾c. in small quantities.

STEEL.—Bessemer billets, Pittsburg, $27.00 open hearth billets, $28.00; San Francisco, bar, 7c to 13c ℔ lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 8½c.; less than 500 lb., per lb., 8½c.; in 25-lb. tin pails, ½c. ℔ lb. above keg price; in 1 and 5-lb. tin cans, 100 lb. per case, ½c. per lb. above keg price. Dry Lead.—In bbl., 1 ton and over, 8c.; do. in kegs, 8½c.

LIME.—Santa Cruz, $1.35 country, $1.25 city ℔ bbl.

CEMENT.—Imported, $3.00@4.00 ℔ bbl.; California, carload lots, $1.80 f. o. b. at works; small lots, $2.10 ℔ bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

LUMBER.—(Retail): Pine, ordinary sizes, $24.00@25.00; extra sizes higher; redwood, $28.00@30.00; lath, 4 feet, $4.50@5.00; pickets, $21.00;shingles, $2.50 for No. 1, and $2.25 for No. 2; shakes, $13.50 for split and $15.00 for sawed; rustic, $28.00@35.00.

NAILS.—This week the basic prices are: Wire, $1.85; Cut, $1.75. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d, Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4d and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

OILS.—Linseed, boiled, bbl., 56c; cs., 61c; raw, bbl., 54c; cs., 59c; Lucol oil, boiled, bbl., 48c; cs., 53c; raw-bbl., 46c; cs., 51c. Kerosene—Pearl, per gal., 17c; Astral, 17c; Star, 17c; Extra Star, 20c; Eocene, 19c; Elaine, 26c; Water White, in bulk, 10½c; Mineral Seal, iron bbls., 18½c; wooden bbls., 21c; cs., 24½c; Mineral Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 15½c, do., cs., 22c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 12½c; do., in cs., 19c; Lard Oil, E. W. S., bbl., 65c; cs., 70c; Neats-foot Oil, pure, bbl., 63c; cs., 78c; Sperm, crude, 53c.; Natural White, 68c; Bleached, do., 57c; Whale Oil, cs., 57c.

BISMUTH.—Subnitrate, ℔ lb., $2.10.

CHROMIUM.—90% and over, ℔ lb., 80c.

FIRE BRICK.—Domestic, carloads ℔ 1000, f. o. b., factory square, $25.00; soap and split, $22.50; arch and wedge, $27.50; skewback, $30.00; circle, $32.00.

FIRE CLAY.—Domestic, ℔ ton 2000 lbs. in 125-lb. bags double, and dry ground, f. o. b., factory, $8.50.

FUSE.—Triple tape, $4.00 per 1000 feet; double tape, $3.55; single tape, $3.10; Hemp, $2.85; Cement No. 2, $3.10; Cement No. 1, $2.75, in lots of 3000 and up.

LITHARGE.—Pure, in 25-lb. bags, 9½@10½c ℔ lb.

MAGNESIUM.—Pure, N. Y., $1.60.

MANGANESE.—Black oxide, ℔ lb., 2¾@4c.

MERCURY.—Bichloride, ℔ lb., 77c.

MOLYBDENUM.—98@99% N. Y., $1.75 ℔ lb.

PHOSPHORUS.—American, ℔ lb., 70c.

RED LEAD.—500 lb. and over at one purchase, ℔ lb., 8½c.; less than 500 lb., 8¾c.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 54c.

SODIUM.—Metal, ℔ lb., $1.

TUNGSTEN.—Best, ℔ lb., 90c.

URANIUM.—Oxide, ℔ lb., $3.40.

Commercial Paragraphs.

THE Traylor Engineering Co. of New York has closed a contract for a large concentrating plant in Guatemala.

THE Main Belting Co., of Philadelphia, during the past year has built, on the latest lines, an addition to its plant, which will greatly facilitate its output and enable it to keep pace with the increased demand for its Leviathan belting.

THE Colorado Iron Works Co. recently sold and shipped impact screens to the following: Hall Mining & Milling Co., Nelson, B. C.; Sunnyside mill, Eureka, Colo.; Eleventh Hour Gold Mining Co., Spearfish, S. D.; Blake Mining & Milling Co., Denver; Wheeling Milling Co., Mine La Motte, Mo. A smelting furnace was likewise shipped to Berlin, Germany.

THE Chicago Pneumatic Tool Co. has closed its Norfolk office in the Chamberlains Bdg. and will in the future open an office in Richmond, Va. The office at 602 Empire Bdg. Pittsburg, Pa., will be closed April 1 and moved to 10 and 12 Wood street. The office has been closed at Seattle, Wash., and a new office opened at 84 Sixth street N., Portland, Oregon.

THE Santa Fe Railroad Co. has ordered 25 trucks built and equipped with patent axles, manufactured by the Railway Axle Manufacturing and Machine Co. of Los Angeles. These axles consist of a ball-bearing device whereby the turning of sharp curves is greatly facilitated. They permit of the wheels turning both in the same direction or in opposite directions or one wheel to turn faster than the other.

THE Cyclone Drill Company of Orrville, Ohio, has purchased the plants, equipment, business, patents, good will, etc., of the Cyclone Drilling Machine Co., and the Presler-Crawley Mfg. Co., and will continue the manufacture of the line of prospecting machines, water well, oil, gas and placer drills, blast-hole drills and economy loaders, double-cylinder gasoline engines, steam-engines and boilers, engineering devices, etc. The plant will be enlarged.

Trade Treatises.

The Cyclone Drilling Machine Co. of Orrville, Ohio, have issued a neat booklet descriptive of their drilling prospecting machinery, for boring for oil, gas and mineral, and for testing placer deposits. The various paraphernalia used for these purposes are illustrated and described.

BOIL DOWN—

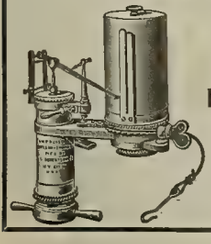
Every argument and you'll find that

"EUREKA" PACKING

Embodies all that's good in any packing.

MODERATE COST—BETTER WORK.
LONGER LIFE—BETTER CARE OF ENGINE RODS.
ENGINE RUNS MORE SMOOTHLY—MORE POWER IS DEVELOPED.

It will cost but little to test these claims.



DO YOU KNOW

Whether your Engine is doing all she should for amount of fuel consumed?

ROBERTSON-THOMPSON INDICATOR

Will tell you and it won't cost much to know.

VICTOR REDUCING WHEEL—WILLIS PLANIMETER
STEAM SEPARATOR—FLAX PACKING, ETC.

JAS. L. ROBERTSON & SONS, Inc.

195 FULTON ST., NEW YORK.

Portable Buildings.

NO 410. STOCK SIZE—12 ft. 9¾ in. by 31 ft. 5¼ in.
Shows supplementary roof for hot climates.
They can be applied to any of our houses.
Two outside and two inside doors, four windows and three rooms, screens, etc.
We will be pleased to send catalogues on application.

EDITORIAL.

UNIFORMITY in reporting the output of mines and mining districts is desirable. In some cases the unit is a carload, in another a pound. Pounds are used for effect, a million of them seeming more than 500 tons. The term 'carload' is vague, for a carload may vary within wide limits; that of a narrow-gauge railroad may hold 10 tons and that of a broad gauge 20 tons or more. We would suggest that these unintelligent methods be discarded; let us agree to use the same unit—the ton of 2,000 pounds.

OUR FRIEND, the shift-boss, may fight shy of Professor Kemp's article on contact zones, because of his use of the graphic formula to express the chemical structure of certain complex minerals. But the matter is not so abstruse as it looks; it explains, better than much writing, how certain minerals are constituted and how they are related to other minerals found along the contact of eruptive rocks and limestones. The investigation of these zones and the determination of their origin, has been one of the most important results of applied geology; it has given many useful data for a correct understanding of an important type of ore deposit. For the needlessly technical kind of writing we have no liking, but this study of contacts made by Professor Kemp is that of a good friend to mining; he gives hints of immediate practical value.

THE Smelter Securities Corporation has not bought the Giroux Consolidated mines at Ely, Nevada, and the negotiations for merging the Boston Consolidated with the Utah Copper, broke down owing to a difference of opinion regarding the amount of ore reserves. In the meanwhile, the Guggenheims are extending their interests in Alaska, having arranged to acquire a consolidation of claims covering the valley of Bonanza creek, in the Klondike district, the intention being to dredge the bottom land and hydraulic the bench gravels. It is understood that $3,000,000 is involved, the scheme being to build a ditch 50 miles long, part of the distance being covered by pipe of four-foot diameter. The business was done through Mr. H. C. Treadgold, an appropriate name. It is interesting to add that Mr. Treadgold was formerly a don at Oxford, from which it is apparent that "the home of lost causes and forsaken beliefs" does not altogether smother the industrial initiative of the modern man.

THE MEASUREMENT of temperature at the bottom of the two deepest mines in Australia—both at Bendigo—indicates an increasing warmth, but less than that due to added depth; the difference being explained by the good effect of ventilation. The deep mines at Bendigo are close together, so as to be easily connected by levels. The Government Inspector of Mines found the temperature at the 3,856 ft. plat of the New Chum Railway mine to be 86° F., while at the bottom, at 4,069 ft., the thermometer registered 88°. The water at the west end of the shaft was 94° and at the east end 96°. In the Victoria Quartz mine, also on the New Chum reef, the temperature at the plat on the 3,824-ft. level was 76°, while in the shaft at 4,040 ft. it was 88°. The water was six degrees warmer. The New Chum Railway is warmer than the Victoria Quartz mine because it has an up-cast shaft, and receives air from an adjoining mine, while the Victoria Quartz receives fresh air through its down-cast shaft. As the mean annual temperature at Bendigo is 60° F., the increase at 4,000 ft. is not excessive.

ANDREW CARNEGIE is quoted as an advocate of the new spelling, and the daily press treats his views as having an important bearing on the matter. Mr. Carnegie's opinions on spelling have no more value than those of his coachman. Why is it that people regard the views of a rich man on every question as necessarily valuable? There is the young Rockefeller's bible class, for example; every Monday morning a large number of daily papers give a report of the vapid utterances offered by him to his class on the preceding Sunday, as if this insipid young man's twaddle was worthy of wide dissemination among intelligent people. It is mere toadying to wealth. This prostration before money debases the self-respect of the community. Mr. Carnegie holding forth on spelling and Mr. Rockefeller, Junior, commenting on the Bible, may be interesting to their immediate acquaintances, but for the press to give them space or for other more thoughtful people to take them seriously on these subjects, is simple snobbery. There are some subjects on which Messrs. Carnegie and Rockefeller could hold an audience breathless, namely, a detailed account of the manner in which they became so overwhelmingly rich; how they dodged the law, sandbagged their competitors, spoofed their associates and fooled the common crowd while they gathered the sheckels that now give them an aureate halo. As to the spelling question, the new scheme reminds one of the phonetic efforts for which small boys used to be flogged.

WE understand that the Mexican Gold & Silver Recovery Company has taken steps to collect royalty from the Guanajuato Reduction & Mines Company, and in the contest to be made by the latter it has been joined by other companies operating at Guanajuato. The agents of the corporation owning the cyanide patents paid an unexpected visit to the Bustos mill—described in our issue of January 13—and held court there under the authority of the local judge. This resulted in the placing of seals upon the doors and cyanide vats, closing down the mill. We trust the dispute will be settled amicably and out of court. Litigation over patent rights is of the most protracted and expensive character to all concerned. As a matter of history, it is amusing to recall the fact that the representatives of the cyanide company tested the application of their process to the silver ores of Guanajuato seven years ago and obtained discouraging results. Since then others have worked patiently at the problem, and now that they are successful they naturally resent the imposition of tribute. However, if the law decides that they are liable, they will doubtless acquiesce with the best grace possible, and in doing so make it more easy for the cyanide company to recognize the humor of the situation, and at the same time display the tactics of sound business by not exacting an unduly heavy royalty from people who have developed their own process after they themselves had failed in its application to the ores of this particular district.

A New Bureau of Geology.

The bill before Congress to establish a Department of Mines and Mining, to be presided over by a new cabinet officer, has been killed; on the other hand, a bill to create a Bureau of Geology and Mining in the Department of Commerce and Labor, has been presented by Mr. Franklin E. Brooks, of Colorado, and it has received a unanimously favorable report at the hands of the House Committee on Mines and Mining. The Bill proposes to transfer the Geological Survey, excepting the Reclamation Service, to the new bureau; of which the present director of the Survey becomes the official head. Inspectors of mines and their subordinates are also to be transferred to this department, which is to be authorized to "investigate, collect data with reference to, and publish and distribute information and reports concerning, the mineral resources and mining industries of the United States and dependent territory, etc." The director of the new bureau "shall have power to gather such data and information in regard to the operation of mines, labor and wage conditions, and in regard to mining machinery, methods, and appliances as will tend to the improvement, economy, and efficiency of mining methods and the safety of mining employees; and generally he shall have power to investigate and ascertain the facts concerning all questions of interest and benefit to such mining industries." All of which is comprehensive indeed. Fortunately, the Bill has been shelved; we hope it will remain in a quiet corner out of harm's way.

As it stands, this Bill is a concession to the popular demand for a mining department, but it is framed so as to increase the bureaucratic tendency of the existing Geological Survey, rather than to carry out the needs of the mining industry. It benefits the Survey in one way, by cutting off the Reclamation Service, which remains under the Interior Department; and it is logical in placing the Survey under the Department of Commerce, where it properly belongs. Beside assuming the duties of the Geological Survey, the new bureau undertakes those belonging to the inspection of mines for the Territories, the investigation of labor and wage conditions, as well as of mining machinery, methods, and appliances, with a view to other improvements, and, finally, the determination of the mineral or non-mineral character of

lands suspended from sale and entry by reason of dispute as to their classification. This last duty the Survey already attends to, when called upon by the Secretary of the Interior. The government inspection of mines is likely to be a dead letter, inasmuch as the Bureau could not act in the States. The investigation of mining machinery, etc., is a dangerous thing for the Survey to undertake; the officers of it are by no means adapted for such work and they will come into conflict with private interests, to antagonize which will be only less harmful to the good of the Survey than to humor them.

Most of our readers take an interest in the useful work of the Geological Survey and to them this accession of bureaucratic powers will seem like a step further in a wrong direction. As an organization of scientific men, the Survey commands the sincere respect of the mining public, as a statistical, industrial and political bureau, it is held in no particular regard. The mining people have expressed a desire for a Mines Department at Washington, it is an impertinence to offer this hybrid bureau in fulfillment of that desire. The Survey should be under the control of a Mines Department; but this is not to be done by tacking a mining bureau onto the existing heterogenous affair of which Mr. Walcott is the distinguished chief. For the geological people to meddle with mine inspection, the examination of machinery or the investigation of metallurgical processes is only to copy existing blunders of administration, as, for instance, the stupid arrangement by which officers of the army are given charge of irrigation problems, for which they have had no training whatever. It all makes for confusion, for inefficient work and, worst of all, for a great deal of jobbery at Washington. Give us the old Geological Survey, shorn of its wood and water excrescences, free from wire-pulling and lobbying; restore it as a corps of enthusiastic scientific men, such as the band of geologists under Clarence King, who made the Survey famous in Europe and tremendously useful in America.

The Impending Coal Strike.

On March 31 the agreement based upon the awards of the Anthracite Strike Commission of 1903 expires, and on April 1, unless an amicable arrangement is concluded, there will be a general coal strike, not in the anthracite districts alone, but also in those that produce soft coal. On January 27 there met at Indianapolis a joint conference of operators and miners representing the bituminous coal-mining industry of Pennsylvania, Ohio, Indiana, and Illinois —constituting the so-called competitive district—and it was decided by an amendment proposed by John Mitchell that all the coal-mining districts "under the jurisdiction of the United Mine Workers of America, whether anthracite, bituminous or block-coal regions, in the United States and Canada" should stand or fall together in their demands for higher wages and other betterments. The miners rejected the proposition of the operators to continue work at the old scale and demanded a 12½ per cent increase; since then, after several conferences, the last of which took place this week, this has been brought down to an irreducible minimum of 5.55 per cent, being equivalent to the restoration of the wage scale of 1903.

Such is the situation in the bituminous regions; meanwhile, the approaching end of the agreement between the operators and miners in the anthracite region of Pennsylvania has led to exchange of views. On February 27 the demands of the mine workers, as represented by a committee, of which John Mitchell is chairman, were forwarded to George F. Baer, the chairman of the operator's committee. These demands included the establishment of an eight-hour day, a readjustment of wages said to be equivalent to a 10 per cent increase, the formation of new boards of conciliation, the recognition of the United Mine Workers and the collection by the companies of the monthly dues payable by the miners to that labor organization. In advocacy of his side, Mitchell urged that the uniform scale of wages was desirable because "men performing precisely the same character, and indeed the same amount of labor, cannot work with any degree of contentment while the compensation received by them is not uniform." The increase of 10 per cent in the rates paid to contract miners was asked on the grounds that the general industrial and commercial conditions of the country "justify an increase of wages to all classes of labor" and, as a further argument, attention was directed to the unprecedented prosperity of the coal railroads as demonstrated by their earnings and by the enhanced value of their stock quotations. As to the eight hours, this was claimed to be the standard work-day obtaining in nearly all the bituminous regions; it was as long as a man can work in a coal mine without injury to himself, and it would not reduce production materially.

In reply, the committee of the operators stated that they stood unalterably for the open shop and declined to recognize the United Mine Workers of America, "an organization controlled by a rival industry," meaning bituminous coal. As to eight hours, they claimed that the loss of time would curtail production and compel expensive machinery to remain idle one hour longer. Uniformity of wages was held to be impracticable by reason of the varying capacity of workmen and the varying conditions under which they labor. In regard to the request that the operators collect from each employee the fixed sum needed for the support of the union, the committee said that they "would not make such an agreement, and as a matter of law they were not permitted to make it." Finally, they fell back upon the findings of the Anthracite Strike Commission and offered to continue the old agreement—based upon the decisions of that Commission—for another term of three years.

So the matter stands at this time of writing. The trouble in the bituminous regions would be readily adjusted save for the attitude of Mitchell and his friends who emphasize their power by involving the anthracite region in a general strike unless the demands of both the anthracite and the bituminous miners are conceded. By the Indianapolis resolution there was given to Mitchell the power to settle labor troubles in mining regions far apart, producing different kinds of coal, working under dissimilar conditions and tributary to antagonistic markets. Here is one of the dangerous elements in the situation. By his evidence before the Strike Commission and by his speeches on labor troubles, Mitchell has shown himself, in our opinion, to be an insincere man, a labor delegate of unusual cheek and a scheming official representing a tyrannical labor organization, the interests of which are not always those of the laborers whom it dominates. On the other hand, the coal operators are represented by five presidents of coal companies, headed by George F. Baer, a man ridiculous in his vanity of power, a narrow-minded egoist who is quite incapable of seeing that working men, just as much as 'coal barons' are deserving of just treatment; in fact, this term 'coal barons,' while it may seem the humorous exaggeration of newspaper scribes careless of words, is indeed a fitting description of the group of men whom the great coal industry has placed in a position of power for which they, just like Mitchell, are unfitted by temperament and training.

The public will resent a general strike; it means the cessation of work over a wide territory, the disorganization of business and severe loss to individuals as well as corporations. During the great strike of 1902 the mine workers lost about $25,000,000 in wages and the coal production fell off 24,600,000 tons; the receipts of the coal companies were reduced $46,100,000 and those of the affiliated railroads $28,000,000, making a total loss, to the parties concerned, of $123,700,000. But this omits the injury to the public, the suffering to the poor who could not buy coal during the winter of 1902 and the crippling of industrial operations all over the country. The losses of the two parties to the strike were made good, for the mine workers got an increase of wages and the operators made tremendous sales of coal as soon as the strike ended; the increase of 50 cents for anthracite put on at the time of the strike gave from 45 to 50 million dollars per annum extra to be divided among the miners and the operators. Who paid the difference? The public. And now they propose to fight again like cat and dog, with the sure result that the consumer will pay for it; for, in the end, whatever increase of wages be paid to the coal miners, the operators will advance the price of their coal, with a little extra on the side. There is no valid reason for a strike; the questions at issue should be submitted to a board of arbitration.

By the Way.

In the current issue of the *Sunset Magazine* there is an interesting article by Mr. Charles G. Yale, formerly, and for twenty-two years, the editor of the MINING AND SCIENTIFIC PRESS. Mr. Yale says:

The man who invented the advertising phrase about California being the land of "sunshine, fruit and flowers" must have been a newcomer, because he omitted the very thing of all which made California famous throughout the world. The Golden State it has been, and is today. It was the gold mines which brought men here to settle it, and the gold mines which kept it on its feet until other resources might be developed. There are sunshine, fruit and flowers in many regions and many States, but gold deposits of note in but few. When one recalls the fact that California has yielded 52.44% of the total gold output of the entire United States since 1792, or close on to a billion and a half of dollars, it seems odd that so startling a fact should be ignored in a phrase intended to advertise the State. With 22 States producing gold, this one has produced one-half of all that has come out of American ground in over a century, the combined product of all the others not being able to reach it. For 57 consecutive years the average annual output of gold in California has been $25,250,000. And yet, after all these years, there are more producing gold mines in California today than any other State in the Union; the total number being, quartz and gravel, 1,185; Colorado coming next with 588. Gold is still being mined in these modern days in 34 counties of the State.

As a gold-producing region California has, among other mining States in the Union, the distinction of holding the record in all particulars. It has made, largest output in any single year; made the by far, the largest aggregate product; made the highest annual average though its mines have been worked over half a century; kept the lead as a gold-producer the greatest number of consecutive years; pursues the largest number of varied branches of gold mining; and has the widest geographical distribution of all its gold deposits.

In giving some brief consideration to the present condition of the mining industry in California, as compared with its past, it may be said that the pioneers were all placer miners, and the pick, shovel, pan, rocker, sluice and long-tom comprised their appliances; the gulches, ravines, river-beds and bars the source of their gold. No capital was required, and no extensive companies needed. Little or no development work had to be done, as the claim paid, or did not, after brief work. Those were the days of individual miners, or unorganized companies of partners. Yet, even under these simple conditions they took out from $10,000,000 to $80,000,000 per year in the first four years. The deep gravels in the now famous ancient river-bed channels were unknown, and quartz was little thought of. Gradually, however, as might have been expected, the available area of this kind of mining was narrowed, as the ground was worked out, and attention had to be turned to other sources of gold supply. This led to the discovery of the ancient channels, buried beneath the lava-capped divides, subsequently worked by drift mining; and those with no lava capping by the hydraulic process, the cheapest operated of all forms of gold mining, and having its origin in California. Attention, too, was turned to quartz as the original of all this surface gold.

With the exhaustion of the open surface gold deposits, the day of the individual miner practically came to an end in California. Then both the character of the mining and the mining population changed. It was no longer possible for the nomadic miner, with a few simple tools, to gather a fortune in a few days from a deposit which nature had concentrated for him in a few yards of earth or gravel. It became necessary to employ both capital and labor to carry on gold mining under the changed conditions. Ditches and reservoirs had to be built for water supply for hydraulic mines; long tunnels run to tap the buried channels under the divides; and shafts had to be sunk, and mills, pumps, hoists and other machinery provided before profit could be made from the quartz mines.

Thus it was that the great body of the miners stopped working on their own account, and were employed for daily wages by the companies which were organized to conduct the operations requiring investment. The miners gave up their nomadic instincts, became permanent residents of the camps or mining towns, taking steady employment in mines and mills, and this condition continues today. Of course, there are still many prospectors throughout the mining regions, as well as miners who work their own 'prospects,' but the majority of the mining population is now engaged in work for the companies. This has resulted in the building up of thriving, permanent towns in all the centers of mining.

The era of speculative mining incidental to newly settled mining regions has long since passed by in California, and the business is, in these days, conducted in as legitimate a manner as farming, manufacturing, etc., profits being sought from the product in the mines themselves, and not from fictitious and evanescent 'stock' values.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and to give information dealing with the practice of mining, milling and smelting.

THE grade of mill plates varies, but about 1¼ in. per foot is a fair average fall.

NATIVE SULPHUR occasionally occurs in gold veins as the result of oxidation of pyrite.

A FEW OPALS of inferior quality have been found in California, notably at Mokelumne Hill.

NUMBER 3 shaft of the Tamarack copper mine, near Houghton, Mich., is now the deepest vertical shaft in the world—5,128 feet.

ONE miner's inch under four-inch head (four inches from center of the orifice to surface of water) will flow close to 13,000 gal. water in 24 hours.

LOW-GRADE copper ores may be smelted if the necessary fluxes and fuel are at hand, and the process is not too expensive to admit of a profit on the operation.

SOME pyrite, particularly amorphous varieties, are hygroscopic, and when brought into a moist atmosphere deliquesce, crumbling into a shapeless, earthy mass.

INFORMATION concerning all the reports of the United States Geological Survey can be obtained by addressing the director of the Survey at Washington, District of Columbia.

THERE is little doubt but that a fault cutting a vein in many instances has had the effect of enriching it. There are numerous occurrences known to 'Concentrates' where this is the fact.

OBSIDIAN is probably more often mistaken for a valuable mineral than almost any other. Among the things for which it is sometimes mistaken by the uninitiated are anthracite coal and pitchblende.

RAISING in a mine is generally less expensive than sinking. Where a long connection is to be made between two levels it is good practice to raise from one level and sink at the same time from that above.

MINERS generally use either common yellow soap or axle grease to 'dope' primers before placing them in wet holes. Either of these serve the purpose well if properly arranged and tied tightly with a piece of twine.

WHEN zinc and copper are placed in contact voltaic action is set up, particularly if moisture be present, resulting in the destruction of the zinc. Salt and lime, and water containing lime in solution, is also detrimental to zinc.

WHERE a narrow strip of slaty or schistose rock is found at the side of a vein in granite, this schist is probably due to the shearing of the granite. Slates in contact with granitic intrusions often develop metamorphic crystals, such as chiastolite.

THE increase in temperature with depth in the mines of the Rand has been determined to be one degree for each 208 ft. of increase in depth. At 1,000 ft. depth the normal temperature is 68.75° F., at 4,000 ft. 83.15°, at 6,000 ft. 92.75°, and at 8,000 ft. (estimated) 102.35°.

THE enrichment of mineral vein and ore deposits by chemical processes which take place near the surface is now generally recognized, and the conservative miner does not feel safe passing judgment on a mineral vein until he has satisfied himself that normal conditions have been reached.

THE most satisfactory method of treating silver-lead-zinc ores is by crushing the ores, separating the zinc from the other sulphides by electro-magnetic separators or otherwise and sending the products to the smelter. This is being done at a number of places in Colorado.

THE separation of lead and zinc sulphides in complex ores is in successful operation at Leadville and other places in Colorado; in British Columbia, and in many other districts. The essential conditions for success are ore rich enough to pay the expense (which must necessarily vary in different places), a good machine and an operator who understands the process.

THE treatment of silver-lead ore containing zinc is attracting much attention at this time, especially at Broken Hill, in Australia, where the problem is to separate an intimate mixture of blende and galena. Several ore flotation processes, such as those of Potter and Delprat, have been used successfully in large-scale tests, and now the Elmore oil process has been modified for the same purpose. Furthermore, the zinc corporation has another promising method in which an air-jet serves to induce the flotation of the sulphides. The principles underlying these ore flotation processes were discussed at length in the MINING AND SCIENTIFIC PRESS of February 24, 1906.

FOR some time past a suit has been pending in the Colorado courts to quiet title to mineral lands under the streets and alleys of the city of Leadville. The Supreme Court of the State is expected on April 1 to render a decision in this matter, which will determine whether the mineral rights belong to the city or to the respective mines. The lower court decided for the mining companies and the city appealed to the Supreme Court.

OLD-FASHIONED mining plants are being sold to mill founders as 'old iron,' and are going into the iron furnaces, and recast in the form of modern machinery of better type, higher efficiency and in every way superior to the old. Hundreds of thousands of dollars worth of old machinery on the Comstock has thus been converted into machines of late design. The old plants were good in their days, but the modern type is better suited to the work to be performed, and is cheaper than the old was in its day.

ORES, containing arsenic and sulphur, when heated, give off fumes of these elements. Arsenical ores give out an odor like garlic when heated, and the smell of sulphur is familiar to all. When mispickel is heated before the blowpipe on charcoal, it yields an abundant, white coating and dense, white fumes, and the mineral becomes magnetic. After a short treatment the residue on the charcoal becomes soluble in hydrochloric acid, with evolution of sulphureted hydrogen (smelling like rotten eggs) and the precipitation of the yellow sulphide of arsenic.

WHERE a vein from 18 in. to 8 ft., with from 6 to 18 in. of low-grade material on one side, occurs, it may be possible by careful mining to stope out the poor ore first, allowing the good ore to stand, removing the latter separately, to avoid mixing the poor with the rich. If one side be softer than the other, this soft ore should be stoped first, whether it be the rich or the poor side, for if the hard ore be first stoped it will be almost impossible to keep out a great deal of the soft rock. The stope may be timbered, if timber be necessary, in the same manner as any other workings of similar width between walls.

TO CONVERT a machine-drill into a trip-hammer, simply upset a piece of drill-steel, forming a proper head thereon, and place this in the chuck in the same manner that you would the drill, tightening the bolts. The machine, of course, should be properly secured by means of strong 'U' bolts to a suitable timber frame, so constructed that the anvil may be placed in position underneath the drill. When all is ready turn on the air, the same as though you were going to drill a hole in the rock. The intensity and speed of the blows is regulated by the amount of air turned in, or by the pressure, which may be controlled. No special valve-gear or any change in the machine is necessary.

MICA occurs in dikes of coarse granite. These dikes are mined in the same manner as veins, the rock being sorted either underground or on the surface, or both. The mica is found in groups of crystals, called 'books,' owing to the cleavage of mica plates which resembles the leaves of a book. These 'books' are split up, the good mica sorted out and cut by machine into as large sizes as the shape of the sheet will admit. These sheets are bound together in packages and shipped to stove manufacturers, and elsewhere. The waste is either cut into small discs and strips for insulation of electric lamps and wires, or is ground and sold for lubrication, the manufacture of wall paper and for many other purposes.

THE fossil remains of a dinosaur were discovered in the Bad Lands of Wyoming in 1899. The ribs of this gigantic extinct animal were 9 ft. long; his tail 60 ft.; his neck 30 ft., and it was calculated that his abdominal cavity, with lungs and entrails removed, would have formed a room 34 ft. in length, 16 ft. in width, with a probable height of 12 ft., a space in which 40 people might find seats. A round steak cut from the ham of this beast would have been 12 ft. in diameter, with a solid bone in the center 12 by 14 in., with no hole for marrow. The animal was 130 ft. long, 35 ft. high at the hips and 25 ft. high at the shoulders, and weighed about 130,000 lb. The skeleton of this gigantic mammal was set up at the University of Wyoming.

ORE is occasionally lost by the settling of large masses on the timbers of the first few sets, near the bottom of a large stope, the tremendous weight of the great mass of ore slowly crushing the timbers and forcing them out of line, causing them to jack-knife, and if filling is not at once resorted to, complete collapse is likely to follow. In one instance where this occurred—as a result of stoping out too large a superficial area—the stope was practically lost, but filling was run in as fast as possible, and the stope abandoned temporarily. A drift was then run in the foot-wall 60 ft. from the vein and in it at distances of 60 ft. square sets were placed and inclined raises started toward the orebody. These were carried into the ore above the cave and the ore removed through them, with very little loss.

SHAFT REPAIRING generally proceeds from the top downward. The work may usually be facilitated by the construction of a chute of two-inch plank, built in short sections, and extending in the shaft from a level to the next above. All pieces of old lagging, waste blocking and rocks can be shoveled into the chute, through which it falls or slides to the level below, where it can be directed into an ore-pocket and from there run into a skip and hoisted into the surface, the chute sections being removed as the repairs progress downward, set after set. If the shaft is to be enlarged, it is best to cut out the additional ground from below, working upward, if the shaft timbers are in good condition. If not, the benching out of the new compartment should be carried on from the top downward, and the shaft retimbered at the same time.

THE strongest form in which a hollow glass vessel can be blown or moulded is the perfect sphere, which is much stronger than a bottle of any shape, of the same thickness and quality of glass. The United States steamer *Albatross*, in the service of the United States Fish Commission, has among the numerous interesting exhibits to be seen in that vessel many hollow spheres of thick glass, which have been submerged in a net to a great depth—15,000 ft. or more—by means of heavy weights attached. These were sunk containing nothing but somewhat rarefied air. Some of them are completely filled with sea water forced in through the pores of the glass; others are partially filled, and some of them broke under the tremendous pressure—over 6,600 lb. per sq. in. Beside these glass globes are specimens of fish caught at the same great depth. Accurate soundings have been made over 3,000 fathoms, or about 18,000 feet.

WHETHER or not a junior apex proprietor could retain possession of his vein after it had united in depth with the vein of another (senior locator), even though the two veins were easily distinguishable, one from the other, and separated by a distinct seam of clay or gouge, has not been determined by the supreme court. Nor has the amount of displacement of a vein by a fault, which is permissible in the identification of a vein so faulted, been fixed by law or the courts. There would probably be no dispute in the event of a displacement of 20 to 50 ft., if the conditions were such as to make the identity of the faulted vein certain, but if the throw were 300 ft. or more, it is uncertain how the courts would view the proposition. In some instances the amount of displacement increases along the line of faulting—starting at nothing it may reach many hundred feet in half a mile. Just where the line would be drawn in determining the identity of such a faulted vein is as yet undetermined.

IN the square-set system of timbering the framing is usually suited to the direction of pressure of the superincumbent mass as demonstrated by experience in each mine. Where there is a heavy downward pressure, such as is often observed where the orebody stands nearly vertical, the timbers are so framed that the posts meet when placed in the set. In veins inclined flatter than 65%, where heavy pressure is evident in the hanging wall side, the caps may be so framed that their adjacent ends butt one on the other. In such cases it was formerly the practice to put in angle braces to aid in sustaining this side and downward thrust. To make this most effective the height and width of the set must be so adjusted that the direction of the angle braces will be at a somewhat higher angle than a line normal to the direction of the pressure, which will assist the timber frame in supporting the weight, in this respect acting in the same manner as stulls. A better arrangement than the angle braces is the filling of the stopes contemporaneously with the extraction of ore, which practice renders the angle braces unnecessary, and usually timbers of smaller dimensions may be used, thus further reducing the expense, while ensuring safety and the complete removal of all the ore.

THE oil engines now in use are designed with their valve mechanism arranged to work either on the Bean de Rochas cycle, or on the two-cycle system. These two types are variously designated, the former being usually known as the Otto cycle, the four-cycle, and occasionally (erroneously) the two-cycle. The other is called the two-cycle, or sometimes single-cycle, the first designation being correct. With those engines working on the four-cycle the succession of operations is as follows: 1. Drawing in the air and fuel during the first outward stroke of the piston at atmospheric pressure. 2. Compression of the mixture during the first return stroke of the piston. 3. Ignition of the charge and expansion in the cylinder during the second outward stroke of the piston. 4. Exhausting the products of combustion being expelled during the second return stroke of the piston. This is the four-cycle engine. In the two-cycle engine the entire series of operations is completed in a single revolution—that is, the passage of the piston from one end of the cylinder to the other and back again. In this type, during the first part of the outward stroke of the piston—that is, until the piston uncovers the exhaust port—expansion is taking place. When the exhaust port is opened the products of combustion are expelled; the piston then moves a little farther forward and uncovers the air-inlet port communicating with the crank chamber. The air at slight pressure rushes into the cylinder, aiding in the expulsion of the burnt gases, and filling the chamber with air already compressed to five or six pounds per square inch, in the crank chamber, completing the first stroke of this cycle. The next stroke (being the inward stroke of the piston) the fresh supply of air and gas is first taken in, when compression of the charge follows and ignition takes place when the piston reaches the back end. These two strokes of the piston, or one revolution of the crank shaft, complete the cycle of operations.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

THE BEST SHAPE FOR A SHAFT.

The Editor:

Sir—Mr. Burrows' discussion in regard to the shape of a proposed 2,300-ft. shaft at Guanajuato is most interesting, but his conclusions, considering the purpose and probable future of his shaft and in view of the practice in the Pennsylvania anthracite coal region, seem to me hardly warranted, for what appears to be a special case, influenced as it was by the expectation of enlargement and by the existence of the old Mexican shaft.

The practice in this region is to hoist a mine-car of coal on a single-deck cage; the cars are usually 10 ft. long and 5 to 6 ft. wide over all, and weigh loaded from 8,000 to 10,000 lb.; this has required a hoisting compartment 8 by 12 to 8 by 13 ft., measuring width to the centers of the buntons, and practically all the anthracite shafts are sunk in multiples of this size, rarely smaller than 12 by 16 ft., and as large as 13 by 48 ft. inside the timbers.

Among the deep shafts are the two Auchincloss shafts, Delaware, Lackawanna & Western R. R. Co., two and three compartments, 1,610 ft. deep; Bear Valley No. 2, Pennsylvania Railroad, six compartments, 1,650 ft. deep; Lytle, Pennsylvania Railroad, five compartments, 1,550 ft. deep; two South Wilkes-Barre shafts, Lehigh & Wilkes-Barre Coal Company, two and three compartments, 1,200 ft. deep; Susquehanna Coal Company No. 1, five compartments, 1,000 ft. deep, etc.; these and many others sunk in the strata of the soft-coal measures prove conclusively that there is no insurmountable difficulty in sinking and maintaining shafts of very large size even in soft rock.

To take up Mr. Burrows' points in order:

First. Cost of Sinking.—The cubic contents of the two proposed shafts in their neat dimensions are as 4 to 5, making apparently 25% more material to be handled in the 10 by 10-ft. shaft; this, it seems to me, is largely an apparent advantage; it is impracticable to sink to the neat lines proposed, and, as far as my experience goes, the excavation will in every case be larger than the proposed neat section, and as the perimeters of the proposed shafts are as 20 to 21 in favor of the 10 by 10-ft., any material removed in excess of the neat section would tend to decrease the apparent difference in quantity, which, in my judgment, would in practice be probably nearer 15 per cent than 25 per cent.

Second and Third.—There is no question in my mind that fewer and deeper holes could be used with less shattering of the sides in the 10 by 10 than in the 5 by 16-ft. shaft. The huge Bear Valley No. 2 shaft, 16 by 54 ft., neat excavation, the largest and deepest in this region, was sunk 1,650 ft. largely through exceptionally hard white conglomerate rock with six rows of parallel holes, the center-cut holes being eight feet and the four outside rows nine feet deep; the shaft was not shattered and required but little blocking in squaring up; the usual charge in these holes was six sticks of 60% gelatine. Such holes and charges would be utterly impracticable in a 5 by 16-ft. shaft, which, unless the sides are to be much shattered (with resulting additional mucking), would necessarily be sunk with much shorter holes and with comparatively light charges.

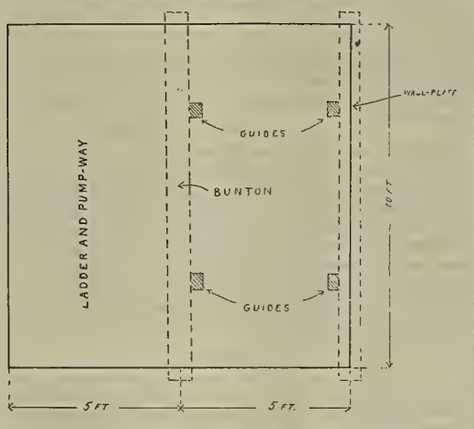
Fourth.—The 10 by 10-shaft will not merely give the larger pump and ladder-way, as suggested by Mr. Burrows, but it gives an immediate possibility of using the shaft for two hoist-ways, one, if necessary, for hoisting water; and with the depth proposed it is more than probable that it will be found advantageous to hoist water from the bottom instead of pumping 2,300 ft. vertically. Further, the 5 by 10-compartment presents possibilities for some mechanical ventilation during sinking without entailing the waste of power involved in using high-pressure air in small pipes for this purpose.

Fifth.—The proposed enlargement of the 10 by 10-shaft can be made from the ladder-way compartment without material interference with the regular hoisting, by simply installing hoisting machinery over this compartment; this is impracticable with the 5 by 16-shaft with a jog at 320 ft., as designed by Mr. Burrows, and hardly feasible even should the shaft be opened 5 by 16 ft. to the surface. The jog in any event is most objectionable and the necessary bends in the pipes in getting from the pump-way at the end into the space left at the side of the old shaft will be a perpetual source of annoyance, beside materially adding to the friction in the pump columns.

As to the timbering, your sketch of the 10 by 10-shaft shows the two hoisting-compartments separated by buntons; this is unnecessary and has long been abandoned in water-hoist compartments here; all that is necessary for the hoisting-compartments is one wall-plate and one bunton, as shown.

With this arrangement the 10 by 10-shaft requires two sticks, each 11 to 12 ft. long, and the 5 by 16 three sticks, each 6 to 7 ft. long, to support the guides, or practically the same length of timber in each shaft for the purpose. In this I am assuming that the sides will stand without timber support, as Mr. Burrows states is the case in the old Mexican shaft which it was proposed to extend. The No. 1 shaft of the Susquehanna Coal Company and many others here have stood for over a quarter of a century without timber other than above outlined.

I cannot agree to the proposition that "there is no way to take advantage of the mucking in shafts of larger section because the buckets can only be hoisted as fast as the machinery will run, etc."; there



is nothing in the 10 by 10 plan of shaft to prevent using two hoists for sinking as is done in all the large shafts in this region, and by putting in permanent wooden or iron guides during the sinking such speed of hoist can be safely attained as will make the hoisting capacity more than equal to the loading.

The reference to precedent in the latter part of Mr. Burrows' discussion seems to be in his mind the

The Shaft Under Discussion. Nueva Luz, Guanajuato.

crux of the matter, and as my practice has all been in the direction of large shafts, I may perhaps be excused for not giving it so much weight.

The greatest advantage to my mind in the 5 by 16-ft. shaft has not been touched upon. It is in a probably more advantageous arrangement of the foot, made possible by the location of the compartments, which permit approach on both sides, while in the 10 by 10-shaft one side is occupied, and all loading of skips or cages must be done from one side only.

R. V. NORRIS.

Wilkes-Barre, Pa., March 7, 1906.

THE ROYAL SCHOOL OF MINES, LONDON.

The Editor:

Sir—The recent gloomy editorial referring to the Royal School of Mines seems rather pessimistic to those interested in its welfare.

It is only too true that the past justifies such a view of the matter, though there is also a brighter side for the optimist. The vital question seems to be whether the welfare of mining education will be considered of paramount importance throughout the course under the new regime. It is generally recognized that the training of an engineer must be founded on a sound elementary education, followed by a general scientific course, without any technical details or early specialization, a fact which suggests the question of the proper connection of technical training with the strictly academic courses of the universities or scientific colleges. The latter should be the training ground for men of the mining school and entirely in sympathy with it. Technical training is not identical with a scientific education, but rather the study of the application of Science to the Arts, and hence the necessity of a preliminary scientific training is self-evident.

At the Royal School of Mines, courses in mine-surveying and metallurgy, probably unrivaled, suffer from the variable ability and sincerity of the students forming the classes, due to the low standard required for entrance, and the fact that much of the preliminary training is in a school which is essentially a training college for teachers. Association of a school of mines with other really good engineering colleges cannot be anything but beneficial, but the relationship of the universities and scientific colleges of Great Britain should be that of mines supplying the raw but valuable material to the smelter to be shipped as base bullion to the refinery of engineering practice.

Keswick, California, March 18, 1906.

BLAST FURNACE *vs.* REVERBERATORY.

The Editor:

Sir—Acknowledging your request for answers to the twelve questions brought forward by James W. Neill, in your issue of March 3, I shall give my replies as briefly as possible:

(No. 1) *On what should the choice of furnace type be principally based? Character of the ore, fuel, fluxes, building materials?*

Character of ore: that is, where the mine product is *all* in the nature of concentrate; it is advisable to roast automatically and then smelt in a reverberatory furnace, on account of the fineness of the product.

The percentage of fuel consumed by this method of smelting is much greater than smelting in a blast furnace; a cheaper fuel can be used, less flue-dust is made to be re-smelted and the cost of briquetting is avoided. I emphasize the word "all" before concentrate, because the advantages of smelting in a blast furnace without roasting are so obvious; one quickly realizes the fact that they will offset the cost of briquetting a great proportion of the burden to be smelted. Eight men and one machine will average 50 tons per day (10 hours) of briquettes (the manufacturers claim 80 tons). I do not consider the cost of burnt lime as a bonding material as anything, as lime is always necessary and burnt lime has its advantages, as explained by me in the *Engineering and Mining Journal*, February 21, 1893, as follows:

"We have been using burnt lime nearly altogether for over eight years, and find that it has the following advantages: It requires no crushing or sledging and can be hauled direct from the car to the charge scale. (2.) The furnaces keep open better, make clean slags and less accretions form on the sides of the furnace. (3.) More ore can be smelted with the same labor and fuel than can be smelted with lime-rock at less cost—e. g., we will suppose a 1,000-lb. charge is to be used, and we require 150 lb. CaO, net, and we are using lime-rock analyzing CaO, 53.86, SiO_2 1% net CaO would be 52% and the charge would be 712 lb. ore and 288 lb. rock. Now if we were going to use the same lime burnt it would have the following analysis: CaO 96.72; SiO_2, 2%, and the net CaO would be 93%. A 1,000-lb. charge would be as follows: 839 lb. ore, 161 lb. burnt lime, showing that 127 lb. more ore can be smelted in each charge with lime burnt than when not burnt, and the same labor and fuel at the furnace and no crushing outside. Any one knowing how many charges his furnace has made can multiply the number by 127 lb. of ore and that by the treatment charges they receive for smelting and find out how much more he has saved to pay the difference between the cost of lime-rock and burnt lime."

In regard to fluxes: if the same care, as a rule, were practiced when making up a reverberatory charge that is used with a blast furnace, perhaps the slag would be as clean, so I consider the flux question a neutral one.

A reverberatory furnace has an advantage over a blast furnace in regard to the character of the fuel, as cheap coal or wood can be used to advantage; but one must consider the enormous amount of fuel required in a reverberatory furnace. See Lewis T. Wright's article on 'Pyrite Smelting Without Coke,' in your issue of February 24th, 1906, where he states the amount of fuel consumed in the repeated operations of the old-style reverberatory furnace as compared with their work at Keswick, where they run their large blast furnaces with little, and at times no coke, making a fair concentration without preliminary roasting. Even in a most modern reverberatory smelting furnace, described by Professor L. S. Austin, in your issue of March 3, 1906, built at the Washoe plant, Anaconda, 102 to 117 ft. long by 19 ft. wide, having a daily capacity of 275 tons, the coal consumption is 21%, which reduces the cost down to $1 per ton of charge; the dollar per ton of charge will fully cover the cost of smelting in a large blast

furnace direct, without preliminary roasting. Of course the cost of preliminary roasting in the improved McDougall calciner, as practiced at Anaconda, Montana, adds very little to the above cost.

The cost of smelting in a blast furnace was given by Wm. A. Heywood, in his contribution to the work on 'Pyrite Smelting,' at $1.05 per ton. This cost of smelting has been still further reduced by the smelting practice at the Granby smelter, near Phœnix, British Columbia.

This does not necessarily imply hot blast in all cases, as some of these low figures have been obtained by the use of a small percentage of coke with cold blast. It is my judgment that a small percentage of coke is advisable in all cases to prevent too frequent freeze-ups. An increased tonnage of ore can be smelted with a smaller percentage of coke with the use of the hot blast.

In isolated localities, where sulphide ore exists and coke is too expensive, by the use of hot blast and the addition of green wood, cut in short blocks, (oak preferred), smelting can be carried on in blast furnaces without the aid of coke, judging from my experience on one or two occasions while in New Mexico, where we tried both lignite, coal and wood. The coal is too soft because of fine made by decrepitation, igniting too near the top of the furnace, but short blocks of green wood (pine was all that we could obtain) gave excellent results, and at this time our blast was not heated to more than 200 to 250° F.

Again, the question of arsenic is a serious one, especially if the company has to market the matte, as arsenic is usually penalized at 50c. or more per unit in excess of one per cent, and arsenic is much easier volatilized in a blast furnace than in the reverberatory, as fully explained in my contribution to *Transactions* of the American Institute of Mining Engineers, Vol. XXXIV, page 422.

(No. 2) *What are the comparative costs per ton of daily capacity of each type of furnace? In the case of the reverberatory, this cost should include the cost of the necessary roasting plant.*

This is fairly covered by the answer to question 1, except to state, smelting direct in a blast furnace without preliminary roasting avoids the erection of a reverberatory roasting furnace, costing anywhere from $18,000 to $25,000, having a daily capacity of from 30 to 40 tons, and the necessary crushing and rolling machinery to prepare the ore for a reverberatory roaster, unless the mine product is already in the form of a concentrate.

(No. 3) *What is the comparative space required for an equal tonnage?*

It is self-evident, without giving exact figures, that the blast furnace has the best of the argument. In comparing the largest reverberatory smelting furnaces and blast furnaces in operation, as described by Professor L. S. Austin in your issue of March 3, where he states that a reverberatory furnace 19 ft. wide, 117 ft. long, has a daily capacity of 275 tons; a blast furnace 56 in. wide by 51 ft. long has a daily capacity of 1,600 to 1,850 tons.

(No. 4) *What is the comparative cost of mechanical equipment for equal tonnage?*

This had best be answered by the mechanical engineer.

(No. 5) *What are the comparative costs of power, labor, fuel, and repairs?*

This has been practically answered in a general way by my reply to question 1, except in regard to repairs. My experience with properly water-jacketed blast furnaces has been that with the exception of the fire-brick in lining the overflow spouts, a blast furnace will go for months requiring very little repairs. There is considerable destruction of steel, but it is small in proportion to the destruction of iron in the machinery and tools used about either an ordinary hand reverberatory roaster or the latest improved mechanical roasting furnace. The fire-box linings, bridge-walls and arches over the fuse-boxes in the reverberatory furnace, which have to be built of expensive fire-brick, are constantly burning out.

(No. 6) *What are the comparative amounts of capital tied up in furnaces of each type, and how does this affect the cost per ton of daily capacity or of output?*

A reverberatory plant would cost approximately five times as much as a blast furnace of the same capacity, and of course interest on capital invested should always be considered, and reverts back to the cost of smelting per ton of ore.

(No. 7) *What are the limiting necessities in the way of fuels for each type?*

This has been sufficiently answered by replies to No. 1.

(No. 8) *What are the comparative losses in slag, dust or middle products?*

All reverberatory furnaces have some little advantage over the blast furnaces when it comes to the amount of flue-dust made, but this is much more than offset by the greater value lost in the slag. From slag samples, which I have had taken from reverberatory smelters, and slag taken from blast-furnace smelters, I have found that blast-furnace slag, as a rule, is the cleanest, but I do not care to state the names of the different smelters where the slag was obtained.

My statement is borne out by referring to James W. Neill's article, 'Blast Furnace *vs.* Reverberatory,' which appeared in your issue of March 3, which shows (in 1904) 0.23 oz. silver and 0.4% copper in favor of the blast furnace, and, in 1905, nearly 0 24 oz. silver and 0 28% copper in favor of blast furnace, which at the present prices of silver and copper is considerable; copper at 18c. per lb. equals $3.60 per unit; 0.4% shows $1.44 per ton slag in the first comparison for 1904 in favor of the blast-furnace slag. The comparison for 1905 shows only 0 28% on copper difference, or $1 per ton in favor of the blast furnace. The difference of composition of SiO_2, and Al_2O_3, in the slag is trifling, being only 0.6% SiO_2 and Al_2O_3 in the first instance and 2.7% SiO_2 and Al_2O_3 in the second, but the blast-furnace slag contains less Fe and more CaO than the reverberatory, and lime is usually the cheaper flux of the two.

(No. 9) *What are the defining limits of each type in regard to slag composition?*

This is a difficult question to answer, but as zinc is but slightly volatilized in the reverberatory furnace, and I am now volatilizing about 60% of the zinc contained in the ore of the Great Western Gold Company in our blast furnace (which we intend to save with a bag-house in the near future, and by experimenting we expect to increase the amount volatilized), otherwise the slag would contain too much zinc to be handled. I consider that I am smelting as much, or more, zinc in the ores, in a blast furnace here than could be handled cheaply and successfully in a reverberatory plant. Our charges here, including lime-rock, contain on an average 15 to 18% ZnO and 10 to 14% $BaSO_4$, yet I am experiencing no difficulty with the furnace assisted by hot blast. The furnace would no doubt have greater smelting capacity with a cleaner ore.

(No. 10) *How do these differences in slags figure out in financial margins per ton smelted?*

This has been sufficiently answered by the comparative analysis of slags already given.

(No. 11) *What method of charging do you advocate for a copper furnace (assuming the atmosphere to be oxidizing)?*

I would advocate the automatic method of charging all large blast furnaces and reverberatory furnaces, excepting in a case similar to ours here, where we have so much zinc to volatilize in the blast furnace.

(No. 12) *Would you bind, in some manner, all fine for use in the blast furnace? Incidentally, what are the difficulties of treating fine ore in the blast furnace?*

No; I would not briquette all fine in the blast furnace, as there is such a thing as having the charge too coarse, but I would bind in some way all the material as fine as flue-dust or concentrate.

S. E. Bretherton.

Ingot, California, March 14, 1906.

THE BEST SHAPE FOR A SHAFT.

The Editor:

Sir—The problem presented by Mr. Burrows in your issue of February 24 is certainly interesting, and it is one that has probably not been encountered by many engineers.

Unless there is a strong probability that more than 1,000 tons per day will need to be hoisted, I should be inclined to favor the proposal of the manager to sink the shaft 5 ft. wide and of suitable length from the bottom of the present 10 by 10 ft. shaft. With this size and using the double-deck cages, the capacity should be considerably in excess of 1,000 tons per day, allowing for a proper proportion of empty trips, etc. A pumping compartment, 5 by 6 ft., should, in the majority of cases, be sufficiently large to accommodate the water-columns, steam-lines, air-lines, wires, etc., and yet leave sufficient space for a small cage running on cable-guides to be used only for hoisting men, tools, timber and other supplies. The cable-guides have the advantage that they can be readily removed to make room for any important work that may be necessary in the pump-compartment, and by having this cage controlled by a small independent hoisting-engine, its movements are entirely independent of the main hoist. If the jog in the shaft were made gradual enough, there should be no difficulty in the handling of the pump-columns and other lines, and I agree with the manager that it is usually found to be easier to handle the sections of the pump through the hoisting-compartment and so avoid the interference of the pipes in the pump-way.

Should there be, however, any great likelihood of a considerable increase over 1,000 tons, the 10 by 10-ft. shaft might be advisable, although the cost of sinking it would doubtless be more than one 5 by 16 ft. The 10 by 10 shaft would give the same hoisting capacity as the narrower section, and whenever the tonnage increased above the possibilities of the two hoisting compartments provided, the shaft could be enlarged to 10 by 15 or 16, as proposed. Instead, however, of making the larger shaft with four hoisting compartments, if the additional length were made to adjoin the hoisting compartments, all the hoisting could be done in two compartments. The Ellison shaft of the Homestake at Lead, S. D., and a shaft at Rossland, B. C., are sunk in this way, and I believe it was the plan of the latter to hoist two one-ton cars on each deck, although at the Homestake they planned to use a two-ton car. A shaft 9 ft. wide was also started in the Leadville district, but it was not carried to any great depth, and has since been abandoned. This, however, was simply a wild idea of the manager, and was not warranted by the tonnage which it was expected to handle.

The Yak Mining, Milling & Tunnel Co., at Leadville, have found it more economical to use a two-ton car in all their tunnel work, as one of these cars can be dumped almost as quickly as an ordinary mine-car. They are, however, too heavy for handling by a trammer underground, and unless some haulage system is installed, the two one-ton cars on a deck would probably be the more satisfactory and would take little longer to place on the cage.

W. Morton Webb.

Leadville, March 12, 1906.

ASCENDING SOLUTIONS?

The Editor:

Sir—In Mr. Jenney's interesting description of the Ontario & Daly-West vein system he ascribes the mineralization to *ascending* solutions, but does not detail the evidences by which that conclusion is reached. If he will consent to do so, I am sure his discussion of the subject will be read with the greatest interest by all those engineers who take up the consideration of the genesis of an orebody in connection with the probabilities of its persistence in depth.

Twice in the past year it would have been important in my examination of copper mines to know positively whether the ore came from below, above, or from the walls.

Martin Schwerin.

New York, March 11, 1906.

GOLD DREDGING.

The Editor:

Sir—If the questions in regard to gold dredging asked by Mr. J. H. Curle, in your issue of January 27, were answered by those who are competent to do so, the results would be of great value. I can contribute a little information concerning the failure of dredging in British Columbia. There were, I think, seven dredges on the Fraser river, near the town of Quesnel, on the Quesnel river, and the Smoky, during the latter part of the '90s. All were failures, none had a chance of success, because in each instance an essential rule of good practice was ignored; in their entirety, they probably include every fault of dredge designing, construction and operation. The prospecting was almost nil, there was no drilling-rig used for the purpose, and no intelligent prospecting of any kind. In design and construction there were all kinds of faulty ones, including even a suction dredge. For managers, any kind of inexperienced man: a promoter, a doctor, real estate agents, anybody but a dredge-master. In view of all this, how could there be any other results than failure?

Doubtless gold dredging in British Columbia will become an important industry as the country develops, and when operators know enough to dredge where the gold is, and also, know how to get it, but the payable, or probably payable, dredging area can not be estimated at this time. Twenty years hence, perhaps, a tolerably correct estimate may be given; at present it can only be said that vast areas are unexplored, and that hundreds of creeks in the known, or probably, auriferous areas are unprospected, and that the area of known dredging ground now available is quite limited. By "available," I mean ground not too remote from transportation facilities. Most of the ground to be dredged in this country is too wet to be prospected by shafts or paddocks; drilling is incomparably cheaper, costing about $5 per foot. If the right kind of rig is used, enough holes put down, and an experienced driller in charge, a close approximation of the ground's value can be obtained.

The conditions here are far from ideal; the season is short, from five to seven months; freight rates from the nearest railway point are from 4 to 10c. per pound; it is far from foundries and all supplies except certain food stuffs. However, because of these very disadvantages there are in this country dredging opportunities in much higher grade gravels than any now available in California. Needless to say that because of the evil repute of British Columbia, as a dredging field, the operator who has to go to the public for his money 'will strike a hard formation'; but if he has the money to put into a well-planned, well-executed and therefore safe dredging scheme, I know of no country more favorable.

Henry Boursin.

Barkerville, B. C., March 2, 1906.

Milling vs. Smelting in the Treatment of Tonopah-Goldfield Ores.

Written for the MINING AND SCIENTIFIC PRESS by FRANCIS L. BOSQUI.

The report that Mr. Charles Schwab has entered into a smelter contract for the treatment of his Nevada ore raises the question as to how far smelters can compete with local mills in the treatment of the silicious ores of the southern Nevada district. I have been for some time of the opinion that this interesting field does not offer an encouraging prospect to the smelter. Recent experiments have shown conclusively that the representative ore of the Tonopah-Goldfield district—not including, of course, the higher grade silver-lead ores of the outlying country—can be handled by modern mill-processes to far better advantage than by smelting, at the current freight and smelter rates. At Goldfield, at the present time, it is unlikely that the smelter, even with much reduced rates, can hope to compete with the phenomenally high extraction obtained from oxidized ore at the Combination Mines Company's mill, the only milling plant in the district in continuous operation. From other properties at Goldfield shipments are being made to the smelters, but only because of the lack of efficient reduction plants. A large and picturesque variety of small custom mills have been in desultory operation at Goldfield for a year or more; but these have been hampered by scarcity of water, in some instances by lack of capital for proper equipment, and, possibly, by unskilled management. The lively competition between these mills has resulted in the adoption of ridiculously low rates for custom-milling, and preposterous guarantees of extraction, involving a hard and unprofitable struggle. This has had the logical effect of discrediting milling in general, and has reacted somewhat in favor of the smelters. And until other mines follow the lead of the Combination Company and erect their own plants, this will probably continue to be the status of milling in the Goldfield district. It is true that the present scarcity of water in the immediate vicinity is a serious obstacle to milling on a large scale; but this is not by any means insurmountable if mine owners will only be convinced of the advantage of owning and operating their own plants.

At the Combination mill the expediency of treating ore under $50 per ton, where an extraction of 90% and better is obtained, is so obvious that no attempt has been made to ship material of this grade. In fact it has not been customary to send anything to the smelter under 20 oz. gold per ton.

The following interesting calculation of comparative net profits from shipping and milling high-grade ore from the Combination mine was made to determine to what point milling could be profitably carried. This table is based upon the Selby Smelting & Lead Company's schedule for September, 1905, as follows:

Value of ore per ton	Smelter discount, freight, and all expense of shipping	Net returns from smelter	Milling costs and losses in tailing, assuming $6 per ton for milling, and 90% extraction	Net returns from milling	Net profit in favor of	
$200	$48.20	$151.80	$26	$174	Milling,	$32.20 per ton
300	50.30	249.70	36	264	"	14.30 "
400	57.90	342.10	46	354	"	11.90 "
500	65.50	434.50	56	444	"	9.50 "
600	65.60	534.40	66	534	Shipping,	0.40 "
700	71.95	628.05	76	624	"	4.05 "
800	78.30	721.70	86	714	"	7.20 "

Freight rate from Goldfield to smelter, $22 per ton for ores assaying above 10 oz. gold per ton; with an increase of 3% for valuation above $300 per ton.

Smelter discount, $1.17 per oz. of gold for ore assaying under 15 oz.; smelter discount, $0.92 per oz. of gold for ore assaying between 15 and 30 oz; smelter discount, $0.67 per oz. of gold for ore assaying 30 oz. and above; $1 per ton haulage from mine to railroad depot; $3 per ton cost of sacks and sacking.

It will be seen from the above that at the Combination mine it is more profitable to mill than to ship ore running even as high as $600 per ton, assuming an extraction of 90%. And, in practice, ore of this grade is being used to 'sweeten' the lower grade material to make a milling product of about 5 oz gold.

It should be explained in this connection, and with reference to the above table, that milling costs and losses would be still further increased by the amount of discount, freight, and treatment of concentrate, cyanide products and bullion, reducing correspondingly the net returns and profit by milling. On the other hand, an increase of two or three per cent in mill-saving over 90% would very considerably raise the net returns from milling.

The following record of a working test made at the Combination mill, on comparatively high-grade ore, has a bearing on this point:

Tons treated, according to actual weight, 63.212; tons treated, by estimate of various products, 63.18, determined as follows: Slime, 14.4 tons; concentrate, 0.78 ton; sand, 48 tons.

Bullion recovery: 813.1 oz. amalgam, or 244.3 oz. bullion 0.942 fine, or 230 oz. fine gold.

Concentrate recovery: 0.779 ton, assaying 24.57 oz. gold, or 19.14 oz. fine gold.

Heading assay, sand, 2.4 oz. gold; tailing assay, 0.27 oz. gold.

Heading assay, slime, 2.065 oz. gold; tailing assay, 0.1425 oz. gold.

SUMMARY.

Recovered from bullion	230.0 oz.
Recovered from concentrate	19.1 "
Indicated recovery from sand	102.2 "
Indicated recovery from slime	27.7 "
Total gold	379.0 oz.
Loss in sand residue	13.0 oz.
Loss in slime residue	2.05 "
Assay of ore, per ton	6.23 "
Total gold in ore	394.05 oz.
Extraction	96.2 %

In the above statement it should be noted that the recovery from sand and slime is indicated only on the basis of careful sampling and assaying, as it was not practicable to make a cyanide clean-up from so small a lot.

A Custom Mill in the Desert.

In reference to the oxidized Goldfield ores, it may be stated that they are peculiarly adapted to milling. The gold is free, but most of it is so extremely fine that it does not readily amalgamate, and a complete cyaniding equipment for handling both sand and slime is absolutely essential.

The sulphide ore at the Combination mine yields to a somewhat different treatment, in which elaborate preliminary concentration is the chief feature, followed by cyaniding. The small quantity of concentrate produced from the oxidized ore will be treated by cyanide. The sulphide concentrate, however, does not yield to cyanide, and will no doubt eventually be chlorinated.

The Tonopah ores, which carry much silver, as well as manganese, a small quantity of copper and other bases, were for a long time considered unsuitable for milling. This view is no longer held by the leading mine managers. Tests now being made on a representative Tonopah ore at an ore testing mill in San Francisco show that an extraction of 90% by a combination of concentration and cyaniding may reasonably be expected in a properly equipped plant. The ore in question carries about 25 oz. silver per ton. If we assume $15 to be the average value of the milling ore in the district, an extraction of 90% and a milling cost of $3 per ton on a 40-stamp basis, we have a total milling expense and loss of only $4.50. This would be slightly increased by the cost of shipping concentrate; but even then the cost would be sufficiently low to discourage shipping and smelting. And if the high-grade ore of Goldfield can be more profitably milled than smelted, then the same rule should apply to the Tonopah ores. Indeed, every present indication points to the distinct advantage of milling over smelting as applied to the silicious gold and silver ores of this whole new district; and with the development of a better water-supply for milling purposes there is no reason why every property of any consequence in southern Nevada should not have its own independent reduction plant.

The Godiva Mill.

The concentration of ore by water is today receiving more attention in the State of Utah than in any other part of the world, and during the past year the State has been visited by many experts. The long series of experiments at the experimental mill of the Utah Copper Co., at Bingham Cañon, are nearly completed. A. J. Bettles is still grappling with the difficulties of stamp-milling the 'porphyry' ore, and E. A. Wall's plant at Bingham contains some novel and apparently worthy features. Gustave Overstrom, professor of metallurgy in the University of Utah, is now installing what promises to be one of the most complete concentration testing plants in the West. The mills mentioned are designed for the concentration of low-grade copper ore; they are to be described soon in these columns.

The treatment of the silver-lead ore of Utah has also been a troublesome problem. Mill after mill has been erected, only to be discarded after a short trial. The most recent work has been done by F. W. Sherman, in charge of the Daly West mill at Park City. Since the first announcement of the success of his experiment,* Mr. Sherman has erected a number of plants, employing his system of classification. That of the Godiva Mining Co., at Knightville, near Eureka, is to be started April 15. The accompanying drawings show sectional details.

An old ore-house was used as the first unit in the construction. Two additions were built, one at each end. This made a complicated arrangement, which could not well be avoided.

On examining section AA it will be seen that the coarse ore is given a preliminary crushing in a 12 by 15-in. Blake, breaking to one-inch size, all of which passes by gravity to the bin supplying the rolls, a set of 14 by 36 in. Details of these are shown in Fig. 1, in which it will be noted that the radical changes from standard rolls are a rubber compression spring and an emery-grinding brick mounting. The former consists of alternating plates of steel and rubber, which give a rigid roll for crushing, but will allow the passage of steel. The latter keeps the roll-surface in good condition.

The product is elevated to the trommels, as shown in section BB. The oversize from the 3-mesh screen of No. 1 trommel passes back to the rolls. No. 1 passing and No. 2 oversize feeds No. 1 jig, and No. 2 passing feeds No. 2 jig. The jig tailing passes through a de-watering screen to the roller-mill, details of which are shown in Fig. 2. It is essentially of the Huntington type, equipped with compression springs that keep the rolls in place. It is supplied with special grit proof bearings and supports. It will also be noticed that the housing is in horizontal, not in vertical, sections.

The re-ground product from the roller-mill is elevated to four classifying tanks, the operation of which was described in the article already cited. The product of each of these classifiers is treated on Frue vanners; the overflow runs through six small settling tanks, their sediment feeding one table. The table tailing is passed through a launder to a cup elevator and carried down to the settling tanks, whence the overflow runs back through the system, supplying much of the water used.

This system is economical, as the same water is used over and over again. After the plant has once been started, no fresh water is introduced except at the front of the concentrating tables. The water used in the rolls, screens, and jigs, and one-half that used on the vanners, is supplied by the overflow from the last fine-ore classifying tank. The plant was designed by F. W. Sherman, and has been constructed by J. G. Johnston.

ANTIMONY is a white, brittle metal, of laminated or crystalline texture. It fuses at a low temperature and readily vaporizes. It is not used in the pure state, but it forms several valuable alloys and compounds. The most important alloys of antimony are type metal, britannia, pewter and anti-friction metals. Type metals consist, essentially, of lead and antimony, often with the addition of small quantities of tin and nickel or copper. Britannia is a white metal alloy, antimony with tin, copper and bismuth, and is much used for table-ware. Pewter is a similar alloy, but it contains a smaller percentage of antimony than britannia. There are several anti-friction alloys which usually go under the name of babbitt metals. One of these consists of 50 parts of tin to five of antimony and one of bismuth, but other proportions are in use.

Defence Against Snowslides.

The accompanying illustrations show the scene of the snowslide which came down last week on the Liberty Bell mine, near Telluride, Colorado. After the catastrophe of March, 1902, when 18 men lost their lives, a substantial barricade of cribbing and rock was built in the path of the slide, directly behind the tram terminal and boarding house. Most of these avalanches are annual; when sufficient snow has accumulated it descends along a path cleared through the forest in previous years; after an unusual snowfall, slides may succeed each other in the same place, but as a rule the big slide at any given locality descends once each spring, when the mass of late snows has gathered momentum so as to hurl it downward over the surface of the earlier falls. In the case illustrated, the slide of last week came down in the same place, and the barrier proved most effective in saving not only the buildings but many lives. Fig. 1 is particularly interesting, as showing how the snow was diverted from the buildings; the top of the barricade can be seen and a man stumbling through the snow. Fig. 2 shows how the stub tram was swept away, while Fig. 3 indicates clearly that the barricade was nearly too short, for the vestibule of the tram-house has been partly demolished. The photograph gives an idea of the wide desolation of mountain-land, into the recesses of which the miner has penetrated, taking his life in his hand and willing to face many months of isolation from the busy life of the valleys far below.

Fig. 1.

Magnesite in California.

The magnesite deposits of California are the only productive ones in the United States, but very few of them are being utilized for the reason that the demand on the Pacific Coast is limited to four or five thousand tons per annum, and the freight rates to Eastern points are prohibitive. The imported material from Greece and Austria is that which is mainly used in this country, as it costs much less than California magnesite when freights to points of greatest consumption are considered. The calcined magnesite, usually in the form of brick, is recognized as the best material for lining basic open-hearth furnaces, cement kilns, etc., and may be employed to advantage wherever high temperatures and chemical reactions are detrimental to dolomite, chromite and silica brick. Large quantities of imported magnesite brick are used, but they are also manufactured in this country (from foreign material) at Layton and Pittsburg, Pa. A factory to manufacture them has recently been started in East Oakland, on the bay shore, opposite San Francisco, the material coming from the extensive deposits in the mountains at the meeting corners of the counties of Alameda, Santa Clara and Stanislaus. For several years almost the entire output of California has come from the large deposit in the vicinity of Porterville, Tulare county, though more small lots have been produced in Napa county. Like many other deposits of mineral character in this State, only those may be profitably utilized which lie close to the railroad lines. Where haulage by team any distance is necessary, the deposits can not compete with similar ones near the main line tracks. For these reasons most of the Napa and Sonoma county deposits are now idle. Magnesite is found in several counties of the State, but only a few mines have been opened. By reason of the opportunity of over-production in view of the limited local market, the prices are not quite so well sustained as formerly. Crude material by carload lots may now be delivered f. o. b. at the mines at $2.50 per ton, and the calcined brings now about $14 to $15 per ton, whereas it was formerly a few dollars per ton higher. The crude material shipped to this city is utilized in the manufacture of carbonic acid gas, which, on being liquefied, is sold in steel cylinders and used by soda-water manufacturers, in factories, refrigerating plants, breweries, bar-rooms, etc. To obtain this gas the crude magnesite is calcined and the remaining calcined material is sold to the manufacturers of wood-pulp paper, where it is transformed into a sulphite of magnesia and used as a digester for the wood pulp. After being used for this purpose, a little lime is added and the 'pearl hardening' of commerce results.

Fig. 3.

It is generally reported that the Rio Tinto Company, the largest producer outside of the United States, had sold its output so far ahead that it was not inclined to offer any more metal at present. Large American producers find themselves in about the same position, while supplies of spot copper are still decreasing. The American consumers of copper are booking orders for their product in by far the largest volume in their experience for this time of the year, and this assures a renewed and sustained demand for the raw material, which will at least have a tendency to maintain the price.

Fig. 2.

Mining Regulations in China.

Consul-General Ragsdale, of Tientsin, forwards a copy of the new Chinese rules and regulations for mines and mining, of which the following are the chief points: The Chinese board of commerce has drawn up 24 articles for the investigation of mines and mining interests in the provinces, and these having been approved by imperial order have been added to the mining regulations sanctioned some time ago. All offices in connection with mining, such as K'uang-wu, Tsang Chu, Ch'a Kuang, Kung So, and others, shall be converted into mining investigation offices for the sake of uniformity. The Tartar generals, viceroys and governors are to select and recommend officials of experience and uprightness who are qualified to be directors and engineers of mining. These shall make surveys and make detailed reports. They must also report on the workings of all present mines, whether by natives or foreigners.

Anyone hindering mining development or investigation by private working or by pleading Fengshui (the interference of the heavenly spirits) will be punished. Merchants or people who need the service of a mining engineer from the office are to provide all expenses. A laboratory is to be attached to each mining investigation office, consisting of two departments—one for experiments, the other for operations.

For the purpose of investigation on Government land, excavations are necessary, and the cropper shall be notified to this effect and no resistance offered on his part. Should any damages be done to his products he will be indemnified by the mining office. Full accounts of the mineral deposits and the necessary steps for development must be filed with the board of commerce. Three classifications are required. If the mineral is of best-quality, transportation convenient, sale prospects large, coal or other fuel procurable, and the machinery can be put up at the spot, the mine may be put down as first class; if transportation is inconvenient, coal or fuel scarce, as second class; and if the mineral lies at great depth and is largely alloyed with other substances, as third class. Notes must be taken as to which mines require native methods and which require machinery.

How to Make Paint Adhere to Zinc.

A writer in *Popular Mechanics* recently explained his method of overcoming the difficulty of making paint adhere to zinc, his desire being to make zinc be the support of a plate surface, and painting the surface with a paint composed of shellac in alcohol containing a solution of pumice stone and lampblack. The method employed was as follows:

A portion of the 'paint' was diluted with alcohol and the surface of the zinc well sand-papered while thoroughly wet with the solution—the intention being not to allow any of the surface to come in contact with the air during or after the operation of sand-papering. The paint was thick enough to cover thoroughly as it dried. When every part had been gone over thoroughly, a number of coats were added, in order that the low places might be filled up and the surface ground with pumice stone. Time has proved the success of this experiment. Many years have gone by, but the coating holds perfectly, and the matter is now brought forward with the hope that the suggestion may have useful application in ordinary painting. The theory on which this experiment was based is that zinc oxidizes instantly wherever a fresh surface is exposed to the air. This oxide is so thin that it is not visible. Nevertheless, it is present, and forms an unstable attachment for the paint as commonly applied, thus preventing the same from coming in absolute contact with the metal itself. The sand-papering operation, under cover of the wet paint, produces a different condition of things.

NIAGARA FALLS.—The first permanent aluminum cable which supplies the Niagara, Lockport & Ontario Power Co., with power from the Ontario Power Co., was stretched across the Niagara gorge, just below the whirlpool, in January. The transmission line will extend from this point to Syracuse. A contract has been made by this company for 25,000 h. p. to be used in the electrification of New York Central branch lines.

On the Formation of Garnet Zones at the Contacts of Eruptive Rocks and Limestones.

Written for the MINING AND SCIENTIFIC PRESS by JAMES F. KEMP.

It has long been known that certain types of ore deposits favor the contacts between igneous intrusions and their walls of sedimentary rock, but the recent great interest in copper mining and the many new properties which have been developed have brought these contacts into greater prominence than ever before. Copper ores are pre-eminently found where eruptives have penetrated limestones and have brought to pass the 'garnet zones,' an expression which has become part of the common speech of the mining profession. The present paper aims to set before the readers of the PRESS the essential points which geologists have worked out regarding the zones, in the hope, not alone of making them the better understood, but of placing at the command of observers actually engaged in mining the course of reasoning by which the conclusions have been reached. At the same time the points may be emphasized upon which additional testimony is needed.

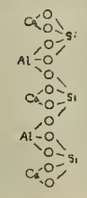
Eruptive rocks that penetrate sediments often exercise upon them profound effects in the way of re-crystallization; they tend to form, locally, new assemblages of minerals which constitute the so-called 'contact zones.' The changes are somewhat irregularly produced and impress an observer no less by their extraordinary development in some places than by their failure to appear in others. These irregular occurrences have been best explained by the suggestion that emitted vapors or solutions are mainly responsible for them. Where the emissions were abundant, the contact minerals appear; where they fail, the zones are lacking. Dry heat does not seem to involve all the necessary factors. Yet this point is one which the student of a new district ought to keep in mind and test in the field.

The nature of a sediment also, to a great degree, determines the result. From pure quartz-sandstones we can expect little else than consolidation by the solution and re-disposition of more silica. From shales which consist chiefly of quartz and kaolin, we would anticipate silicates of alumina, since silica and alumina are the chief components. It is natural, therefore, that andalusite, Al_2O_3,SiO_2, should be the characteristic mineral of such zones. Sillimanite, likewise Al_2O_3,SiO_2, is also common. Should there be, as often happens, some iron oxide, or some magnesia or lime in the shale, we may expect staurolite, $HAl_5FeSi_2O_{13}$ or $HOAlO, 2Al_2O_3FeO,2SiO_2$; biotite $(MgKH)Al_2(SiO_4)_3$, and now and then a garnet.

When limestone constitutes the walls, the simplest result is to change them to marble; and often when they are fairly pure calcium carbonate, this beautiful, white crystalline rock is almost the sole result. Marbles thus produced are sometimes looked upon with favor as ornamental stones, but it is rare that they are sufficiently uniform in grain or regular enough in cleavage to answer. Spots and checks of contact minerals are the rule, and indicate the places where other bases were present in the original rock.

If we imagine the original limestone to have been impure or earthy, we know that the admixture of foreign material would add to the carbonate of lime the following bases, magnesia and iron oxides as carbonates; alumina as the hydrated silicate, kaolin, $2H_2O,Al_2O_3,2SiO_2$; and free silica, in the form of comminuted quartz. From the new combinations of these bases with silica, a variety of minerals may form under the influence of the heat and heated vapors or solutions from the eruptive. Thus the most natural is the mineral wollastonite CaO,SiO_2, and this we find not uncommonly, and sometimes in great abundance. The next in simplicity of composition is the variety of pyroxene, diopside, which contains both CaO,SiO_2 and MgO,SiO_2, often with a trace of FeO,SiO_2. Tremolite, the amphibole of practically the same composition, is not common, although not entirely unknown. This seems surprising, because it is a frequent component of marbles produced by regional metamorphism.

As we pass to the next more complex mineral we meet garnet, which is on the whole the most widespread and characteristic of those present. Garnet is the name of a group of minerals, each of which involves a protoxide and a sesquioxide base. They are all salts of orthosilicic acid, H_4SiO_4, of which we have three molecules with 12 bonds of affinity. These 12 are satisfied with three dyads and two triads, and the several varieties of garnet are due to the different combinations. Thus, grossularite, one of the commonest, contains $3CaO,Al_2O_3,3SiO_2$, which we may expand in a graphic formula as follows:

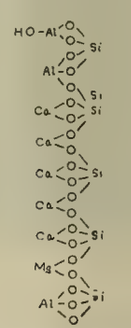


Grossularite really means 'gooseberry stone,' the name being derived from *grossularia*, the botanical name of the gooseberry, and the allusion is to the pale green color and, of course, rounded crystals of some varieties; but we also find yellowish and light brown varieties as well. Cinnamon stone or cinnamon garnet, both common expressions, refer to those with the latter hues. All who have seen garnet zones will recall the frequency of greens and browns, especially in the dense, massive mineral with its peculiar, greasy look.

But we have reason to believe that with the grossularite there is often a large admixture of the lime-iron garnet, andradite, $3CaO,Fe_2O_3,3SiO_2$, and probably to a degree not generally appreciated. This is also light green, yellow, yellowish brown and even darker in its color, and may without analysis be easily mistaken for grossularite. In fact, upon this point there is much need of additional records of actual quantitative composition, since the general disposition of writers has been to call the garnet, grossularite; and reason about it upon this basis. Later on, this point will be again referred to, but it may be remarked, in passing, that iron oxide in its general relations is a more soluble base than alumina, and, as far as we know, may be supplied to the limestone from outside sources during re-crystallization more easily than alumina.

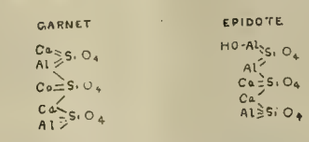
The two lime garnets, grossularite and andradite, are naturally to be expected along limestone contacts as the predominating varieties, but there seems to be no reason why we should not also find at times the iron-alumina variety, almandite, $3FeO,Al_2O_3,3SiO_2$, and even still others, since all of their components are obviously present; nevertheless, experience hitherto justifies us in emphasizing the ones first named and in merely mentioning the others as not improbable.

Of wide occurrence with the garnets are two other lime-silicates, vesuvianite and epidote. Vesuvianite was named because of its frequent development in the limestone blocks which are torn off by the uprising column of lava from the limestone walls of the conduit at the volcano, Vesuvius, and which are then cast out upon the slopes of the crater. Vesuvianite is a more complicated molecule than garnet, but it is nevertheless a not difficult one to understand. Its composition as given by Dr. F. W. Clarke is $5CaO,MgO,Al_2O_3,AlO,OH,5SiO_2$, which means that five molecules of H_4SiO_4 have been combined with five of lime, one of magnesia, two of alumina, and one aluminum, of whose three bonds two are satisfied by one oxygen and one hydroxyl, HO. Expanded graphically, vesuvianite becomes



It often happens that considerable FeO may replace the CaO, and some Fe_2O_3 the Al_2O_3; yet it is clear that we are dealing with essentially the same components as in the case of garnet, and that all of them are such as to be expected under the circumstances.

Epidote is closely akin to garnet in composition, its formula being the same three molecules of H_4SiO_4, whose twelve bonds of affinity are satisfied by two aluminums, two calciums, and instead of a third calcium, as in garnet, a third aluminum, one of whose bonds is already satisfied by hydroxyl. Thus aluminum, with two unsatisfied bonds, may take the place of one dyad calcium. Ferric iron may, and does in large part, replace the aluminum just as in garnet. Epidote and garnet may thus be written side by side,



In studying a garnet zone, therefore, it is important to first determine accurately these several minerals, and then selecting specimens of as great purity as possible, submit them to analysis to decide upon the actual composition of the minerals present. If the mineral is finely crystalline, the microscope alone enables us to make precise determinations; and unless we have reasonably accurate determinations, we cannot of course draw well grounded conclusions.

Beside the lime-silicate minerals already mentioned, magnetite in bodies of considerable size is not infrequent in the zones. Specular hematite, often called specularite, is a common associate, and chalcopyrite or lean copper-bearing pyrite is the usual mineral which gives economic value to the deposits. Quartz likewise appears in veinlets and druses. Fluorite, molybdenite and a few other minerals make up the list of these rare ones. They do not affect in any marked degree the large features of the problem upon which it is here the desire to focus attention.

It is evident that to produce the compounds mentioned there must be either a combination of the silica, alumina and iron of an earthy limestone with the lime of the calcite, attended with the elimination of great quantities of carbonic acid; or else there must be the contribution, from the eruptive, of the silica, alumina and iron to a pure limestone with equal elimination of carbonic acid. From one or the other of these interpretations somewhat important deductions are to be drawn, as will be later shown; and to the determination of this question close attention should be paid by an observer in a new district.

If, for example, an intrusive rock cuts a series of sediments involving several different kinds of limestone; and if we find contact zones where the limestones are known, by analyses or by visible inclusions of chert or by evident shaly character, to be impure; then we naturally conclude that the lime-silicates have been formed out of the materials originally in the sediment. The conclusion would be corroborated were we to observe also that where the eruptive cuts the beds of pure calcite, only marble appears. These were the relations observed by Dr. Joseph Barrell near the Elkhorn mine, Montana, and described several years ago.*

Professor W. O. Crosby† found in Washington Camp, Arizona, that the zones were developed in a cherty limestone and that rims of wollastonite might even be recognized surrounding unaffected nuclei of chert. The zones followed the cherty streaks for a distance from the eruptive, and now appear in the midst of the enclosing sediment which is itself at most changed to marble. Professor Crosby naturally concludes that the garnet zones are the results of the re-crystallization of the cherty limestone, although he does not give any analyses to show that the necessary alumina, to afford the 22.7% required by grossularite, is in the rock.

This general statement and the two cases cited, undoubtedly represent the usual view, and where the coincidence of impure strata and garnet zones appears, the interpretation is well based.

But, on the other hand, I have described in detail, with analyses, a case in the State of Tamaulipas, Mexico,‡ where the limestones were not earthy and where they contained in the cases tested but 4 to 5% SiO_2 and less than 1% Fe_2O_3 and Al_2O_3. It seemed impossible to re-crystallize from raw materials of this character garnet in thick zones and yielding on analysis 37.15 SiO_2, 6.98 Al_2O_3, and 19.40 Fe_2O_3. The zones surrounded huge blocks of the limestone included in a laccolithic mass of eruptive rock, and there is no escape from the conclusion that from the eruptive must have come the necessary silica, alumina and iron oxides.

These cases will serve to bring out one of the crucial points in the whole study of the contacts, and one upon which more testimony, fortified by analyses, is desired. The general association of the minerals is now understood, but before indulging in explanations of origin we emphatically need to know the actual composition of the original rocks which are believed to have undergone the changes, and the composition of the end-result. We may then speculate intelligently as to the nature of the process. Perhaps it is not too much to hope that chemists at smelters or assayers at mines, dealing with these ores, may, in spare time, make the determinations, once the connection is seen.

To Prof. Barrell, whose work was cited above, we also owe an exceedingly important and acute suggestion. Starting with the belief that the zones were produced by the re-crystallization of materials already in the limestones, and with the fact that as present in the sediments these materials were in the form of calcite, CaO,CO_2; magnesite, MgO,CO_2; kaolinite, $2H_2O,Al_2O_3,2SiO_2$; limonite, $2Fe_2O_3,3H_2O$, and quartz, SiO_2, he was able to show that the combination of the silica with the lime, magnesia, alumina and iron oxide, one or several, involved the elimination of the carbonic acid and the water. Thus, if we have 100 parts of a sediment containing

41.7	Kaolin, $2H_2O,Al_2O_3,2SiO_2$
9.8	Quartz, SiO_2
48.5	Calcite, CaO,CO_2
100.0	

it will yield

72.8	Grossularite, $3CaO,Al_2O_3,3SiO_2$
21.4	Carbon dioxide, CO_2
5.8	Water, H_2O
100.0	

The carbon dioxide and the water, 27.2% of the whole by weight, pass off and, therefore, leave a series of empty spaces.

If, now, we divide the above percentages of kaolin,

*Physical effects of Contact-Metamorphism, *Amer. Jour. Science*, April, 1902, 290. Weed and Barrell. *22nd Annual Repl.* U. S. Geol. Survey, Part II, 399.

†*Bulletin*, Amer. Inst. Min. Eng., Nov., 1905, 1217.

‡*Bulletin*, Amer. Inst. Min. Eng., July, 1905, page 885.

quartz and calcite by their respective specific gravities, we will obtain their relative volumes:

41.7 ÷ 2.5 = 16.7 volumes of kaolin
9.8 ÷ 2.6 = 3.8 volumes of quartz
48.5 ÷ 2.6 = 18.7 volumes of calcite

39.2 volumes of minerals in the sediments.

If the general term 'volumes' proves confusing, we may call them cubic inches. Then a mixture of 16.7 cu. in. kaolin, 3.8 cu. in. quartz, and 18.7 cu. in. calcite, will have of each, by weight, 41.7% kaolin, 9.8% quartz and 48.5% calcite.

After the metamorphism, we have grossularite remaining, while carbon dioxide and water pass off; 72 8% grossularite divided by 3.5, its specific gravity, gives 20.8 volumes of grossularite, 39.2 – 20.8 = 18.4 volumes of the original sediments lost as evicted gases; 18.4 divided by 39.2 indicates 47% by volume lost. That is, if we were to have sediments of the above composition re-crystallized by contact metamorphism, the resulting rock ought to have 47% of its volume open spaces. All these calculations are adapted from the paper of Dr. Barrell in the *American Journal of Science* as cited above.

We may now test these calculations by experience. In the first place, do we ever have a sediment of the composition assumed above? When re-cast, the mixture of kaolin, quartz and calcite, which yields grossularite, is

SiO_2	29.1	
Al_2O_3	16.6	
CaO	27.1	Calcite 48.5
CO_2	21.4	
H_2O	5.8	
	100.0	

Limestones of this general composition are not unknown, although not especially common. Thus, if we look through the 988 analyses which have been compiled by Dr. Heinrich Ries in *Bulletin* 44 of the New York State Museum, we will find that something under five per cent of those given will be suggestive, and they are mostly earthy limestones such as might be considered for hydraulic cement. Thus, a rock from New Lisbon, Columbiana county, Ohio, Analysis 726 of Ries, or Ohio Geol. Sur. V. 1109, gave the No. 1 quoted below. Another, No. 2 below, or No. 589 of Ries, is the portland cement rock, near Belvidere, N. J., from the N. J. Geol. Survey, 1900, p. 95. Finally, No. 3 is the grossularite mixture repeated for comparison.

	SiO_2	Al_2O_3	Fe_2O_3	CaO	MgO	CO_2	H_2O
(1)	36.69	15.17	4.82	15.24	3.73	16.07	7.6
(2)	27.9	7.89	1.7	32.1	1.4	26.78	...
(3)	29.1	16.6	..	27.1	..	21.4	5.8

From a limestone having the composition of the first analysis with its high SiO_2, diopside or wollastonite would be quite certain to crystallize in addition to garnet. The same is true of the second on account of the low alumina. Hence, in general, we recognize that limestones adapted to yield the zones of lime-silicates are well known.

But we may get some light upon the question as to whether or not the eruptive has contributed silica, alumina and iron-oxide by observing whether the garnet zones exhibit 47% of voids or some similar amount which would be yielded by the re-crystallization of sediments. If we find them, then the case is favorable to the re-crystallization of materials already present. On the other hand, if the zones are dense or very slightly cellular, as has been the case in some instances, their development without contributions would be impossible. The new silica, alumina and iron oxide would, of course, take the place of the ejected carbon dioxide and leave few if any empty spaces. No interpretation of the phenomena can be adequately developed without considering these points.

Again, if we find large bodies of magnetite along the zones, mingled with garnet and copper ore, and yet have no reason to infer proportionate percentages of iron in the limestone, an additional point of evidence looking toward outside contributions is afforded. Or if the feldspars, orthoclase or albite, appear in the zones, both being foreign to limestones and yet natural contributions from an acidic eruptive, we find another bit of evidence.

So far as the temperature of the processes of re-crystallization are concerned, the recent investigations of Messrs. E. T. Allen and W. P. White, of the United States Geological Survey,* have given us some reliable data. These two investigators have carried on some careful experiments upon the behavior of wollastonite and have produced it artificially under circumstances admitting of accurate heat measurements. They find that wollastonite cannot be produced under normal pressures above 1,180° C. At the higher temperature pseudo-wollastonite results, a mineral not known in nature, and of a different crystal system, although of the same chemical composition. As pseudo-wollastonite cools, it reverts to wollastonite at this critical temperature, unless special precautions are taken. From a glass of the composition of wollastonite, obtained by quenching a melt in water, the mineral crystallizes as low as 860° C. The fusing point of the acid eruptives which are the common products of the zones is believed to be somewhat above 1,200° C., and when injected the mass may have been much higher. So far as wollastonite is concerned, therefore, the temperature of its formation could not have been higher than 1,180° C., and may have been 200 or 300° lower, so that it would appear to result during the cooling stages but while the eruptive and its bounding walls were still highly heated.

Another interesting topic in connection with the zones is the determination of the order in which the minerals have crystallized. Just as in the study of the eruptive rocks, if we find one mineral tightly enclosed in another the outer one is later than the inner one. If we find a well crystallized one sharply abutting against another that molds around it, the good crystal is the older. If we find veinlets cutting across other minerals, their filling is later than the walls.

In the zones we often see veinlets of quartz and calcite cutting the lime-silicates or the same minerals forming crusts over the linings of vugs and druses, and therefore clearly the last to form. In the latter relation we note also chalcopyrite and may not infrequently cause it to break away from well-developed garnets, leaving impressions of the latter. Chalcopyrite may also be seen in veinlets cutting through the masses of magnetite and must therefore be classed among the late introductions.

Black Bear Adit, Le Roi Mine.

But it also appears as inclusions in the lime-silicates and gives evidence at times of dating well back to the early stages of the process, so that evidence is at hand leading to the conclusion that its introduction has been quite continuous. When the chalcopyrite undergoes oxidation it yields chrysocolla as its most frequent product provided no calcite is near to precipitate the carbonates.

Beside the usual run of experience mentioned above, there are others less common and forming notable departures from the rule. Mr. F. L. Ransome, for example, has described the exceptional case at Bisbee, Arizona, where there is next the eruptive a zone of quartz and calcite a thousand feet across. Outside of this comes the dense and finely crystalline belt of the lime-silicates containing the orebodies. Again, as at San Pedro, New Mexico, Washington Camp, Arizona, and Nombre de Dios, Durango, the metamorphism has spread along certain beds to a considerable distance from the eruptive. One may question whether this relation is due to the especially favorable, original composition of these beds; that is to their silicious, aluminous character, or to their more open texture, so that heated solutions or other exhalations from the eruptive found their way along them and developed garnet and its boon companions. Many such questions will confront the thoughtful observer when face to face with actual cases.

The contact zones, in conclusion, are extremely significant in their general relations to the problems of the ordinary veins, which are connected more remotely than they are with igneous phenomena. The zones give us a positive and tangible result of igneous influences; afford a point of departure from which to lay out a traverse into the hazy regions of speculation, and as regards the source of their minerals, whether non-metallic or metallic, they present fewer difficulties. They therefore deserve study, not alone for their own inherent interest, but because they shed light upon questions which greatly need it.

*On Wollastonite and Pseudo-wollastonite, *Amer. Jour. Sci.*, Feb., 1906, 89.

The Le Roi, Centre Star and War Eagle Mines.

Written for the MINING AND SCIENTIFIC PRESS by D'ARCY WEATHERBE.

The names of this group of mines probably convey more of the concrete to the average mind than those of any others in British Columbia, not altogether on account of their richness, production or prospects, but chiefly because their development is contemporaneously bound up with the famous boom of 1896 and its collapse about 1899. These three mines were located in 1890 and the discovery ore assayed from $25 to $40. Their subsequent financial history is much involved in litigation and the maneuvers and schemes of capitalists. Nevertheless production has continued fairly steadily since 1894 and still goes on apace.

The output of ore shipped from and crushed at the three mines during the year ending December 31, 1905, was as follows: Le Roi, 110 838 tons; Centre Star, 95,550 tons; and War Eagle, 61,500 tons. The previous tonnage up to December 31, 1904, was, Le Roi, 974,785; War Eagle, 240,455; Centre Star, 226,648. The average value of the above tonnage was about $16 per ton in gold, silver and copper.

These mines are situated on the southern slope of Red Mountain at an altitude of about 3,600 ft. above sea level and about a mile from Rossland, a town of 6,000 people, situated on a shelf of the mountains below the mines. The sketch (Fig. 1) shows the relative position of the properties and roughly the positions of the shafts and the strike and dip of the veins. The geological conditions have been ably described and mapped by the Canadian Geological Survey and by Edmund B. Kirby, a former manager.* The rock in which the veins occur is augite porphyrite, generally of a dark grayish color and crystalline texture varying in coarseness, though in the lower levels fine-grained ash rocks are seen, so changed by pressure and other metamorphic action as to resemble, in the schistosity developed, the bedding of slate. The veins are fissured zones of the country rock, the latter having been replaced by pyrrhotite through aqueous agency. Later enrichment by the same process has deposited chalcopyrite and gold at specially favored spots throughout the friable pyrrhotite.

Numerous trap dikes intersect the veins, generally at an acute angle and often accompanied by faulting. These dikes vary in crystalline texture more than the surrounding porphyrite, and range from a fine-grained rock to one containing crystals of augite plagioclase and patches of quartz, etc., occurring as large as three-eighths of an inch in diameter. From the fact that these, in some cases, contain mica (generally biotite) and sometimes do not, they are roughly classed at the mine as 'mica' and 'non-mica' dikes. Their effect on the enrichment of the orebody is not often clear, though they plainly acted as barriers to the deposition of mineral, as shown by Fig. 2, which is a sketch of part of the 700-ft. level in Le Roi mine adapted from Mr. Kirby's description.

CENTRE STAR MINE.—The vein dips at an angle from 62 to 75° in the direction shown in Fig. 1, and is entered by a shaft on the dip now over 1,600 ft. deep vertically. This is divided into three compartments, two for hoisting and a ladder-way. Cages with skips suspended beneath are used and are supplied with a safety-hook to prevent overwinding. This is tested every week as are also the 'dogs' on the cages. Large stations are cut at each level and bins underneath deliver the ore into the skips. Nine levels have been driven and the shaft which is in process of sinking is 365 ft. below the No. 9 level. In the sinking, a steel tub hoisted by an auxiliary engine on the level is used; it is operated through the ladder-way, the main portion of the shaft being bulkheaded to prevent danger to the men working below. The hoisting machine used here is not geared, but is driven by a paper disk friction-pinion and is almost noiseless in operation. The method of timbering is by square sets. Originally square timbers (10 by 10 in.) were used, the posts placed seven feet apart at centers and with the caps butted as shown in Fig. 3. The posts are eight feet high. Instead of the greatest pressure being lateral as at first arranged for, it is chiefly from the top and the crushing of the caps resulted as shown in Fig. 3 and produced a point of weakness in the cap at its junction with the post. To remedy this, round timbers are now used and a tenon is cut on the posts six inches wide so that one post rests directly on the other (Fig. 4). The distance between posts has also been reduced to five feet four inches. On account of the extreme irregularity of the orebody and the numerous faults and dikes which displace it, diamond drilling and crosscutting are resorted to largely in exploring the ground. Under the best conditions, however, the diamond drill is a more or less unsatisfactory means of doing this work. Even crosscuts often fail of their object as will be shown by the following incident which will also illustrate the erratic nature of the deposits. Several years ago a crosscut was driven from the No. 5 level in the War Eagle mine to intersect a body of ore that had been proved close at hand by a drill-hole.

*The Ore Deposits of Rossland, *Journal* Can. Min. Inst., Vol. VII.

The crosscut was pushed considerably farther than the supposed position of the orebody; but nothing of value being discovered, it was abandoned. During the past year, however, on driving back on a portion of the vein that had been overlapped by faulting, a rich pocket of ore averaging $40 per ton was extracted and found to be literally within a foot or two of the crosscut! Over $26,000 was taken out of a small chamber on the level and the deposit is supposed to extend beneath the crosscut; a raise from the No. 6 level is now in similar ore.

The numerous comments and reports that, through ignorance, constantly appear in irresponsible periodicals regarding 'strikes' of ore, as they are termed, give to the uninitiated reader, and probably to the foreign stockholder, entirely false impressions, and must often be responsible for much of the bewilderment that exists in the minds of the latter. Doubtless, too, they are the mischievous cause of much of the bickerings and machinations that go on among the directorates of companies controlled by foreign capital. Two recent instances, at the above mines, may be cited as an illustration. Early in February several reports appeared, and were copied, of an enormous strike of ore that had been made on the eleventh level of the War Eagle mine. As a matter of fact, the management had for months been driving their usual crosscut from the shaft at the eleventh level to intersect the vein at the point of the so-called strike, the ore having been previously proved by a bore-hole; and although there was the same chance of local change in the orebody as has been exhibited at other places in the mine, yet the intersection of the vein at this point partook in no way the character of a *discovery* such as would be intimated by such newspaper reports. With regard to the so-called 'strikes' in Le Roi mine, west of the Josie dike, the chance of finding ore exactly where anticipated might be slightly less than in the above case, but the laborious and expensive development work carried on previous to encountering the orebody again was nicely calculated, both as to time and place. It is rather hard that the carefully thought-out plans of these and other capable managers should, on their successful culmination after months of toil, be ruthlessly assigned to chance by some scoop-gatherer.

As noted above, these mines have attained a vertical depth of 1,650 ft. and, so far as I was able to gather, still show promise in depth. The Centre Star vein has been traced easterly for a long distance, but beyond the mine it has not yet been proved in depth. The proving of the continuity of Le Roi orebody beyond the Josie fault opens up a large area of ground and several other veins occur on these and adjoining or near-by properties which, on testing, may reasonably be expected to warrant the continued permanence and prosperity of the camp.

The workings on the War Eagle vein are connected by crosscut with the Centre Star mine; the method of working is practically the same as at the Centre Star, though the vein is found to flatten as depth is gained, and at the No. 11 level a crosscut, 750 ft. long, from the shaft was found necessary to reach it. Fig. 5 is a section through the War Eagle shaft and shows the flattening of the vein, which at the bottom appears to be pitching at a steeper angle. It is intended to discard the shaft and headworks of the War Eagle mine, and tram all the ore from here to the Centre Star, where the plant will be centralized.

The ore from both the Centre Star and War Eagle is dumped over coarse and fine grizzlies and the oversize is hand picked. At the surface the Centre Star waste is trammed by electric motor (see photograph), hauling 12 cars of two tons' capacity each to the dump trestle. The cars underground are from 1,500 lb. to one ton capacity, but are seldom filled to the top.

At Le Roi mine the methods of working are similar to those employed in the other Rossland mines, though the orebodies and consequently the stopes are generally wider (up to 140 ft.). Round timbers are used in the sets. The posts are eight feet high and are placed five feet four inches apart; the caps are butted. The shaft is 1,350 ft. deep vertically, and below the 1,350-foot level a winze has been sunk for 300 ft. The shaft is of five compartments, as per sketch. The cages in the two compartments, 5 ft. 4 in. by 4 ft. 2 in., are used for men and timber and the other two compartments, 6 by 5 ft., are for ore and waste. The skips in these larger compartments have a capacity of four tons each. The cars underground hold about 1,600 pounds.

At the 300 ft. level an adit called the Black Bear tunnel runs out to surface, and through this all timber and supplies are taken underground. Air, steam and discharge pipes and electric wiring also are carried through this level. (See photograph.) A Smith-Vaile triplex pump, size 7½ by 15 by 3, at the 900-ft. level, pumps eight hours per day and lifts 60,000 gal. to surface. It is run by dynamo. A No. 3 Knowles pump at the old East shaft, on the same level, pumps three hours per day and discharges at the sump of the Smith-Vaile pump. On this level there is also another Knowles plunger pump, outside packed, 16 by 8 by 12, which is installed as a reserve. At the 1,350-ft. level a Cameron station pump, 16 by 7 by 12, runs eight hours per day and lifts to the 900-ft. level. The other pumps, a Knowles 10 by 4 by 7 and a Knowles 8 by 3 by 10, are used in tandem in case of accident to the Cameron pump. On the surface the timber shed contains a timber framing machine; this is operated by air power and has proved economical both in time and labor. An extensive machine-shop which aims to supply all parts required, except castings, is run by compressed air.

The boiler plant includes two Heine water-tube boilers, 125 h.p. each; three Fraser-Chalmers return tubular, 100 h.p. each; three Jenckes, 90 h.p. each; three Jenckes, 80 h.p. each. The remainder of the surface plant is as follows: Two Rand cross-compound condensing air compressors, with inter-cooler; stroke of each, 48 in.; gauge pressure, 100 lb. These supply 3,360 and 3,000 cu. ft. of free air per minute, respectively.

The hoist for cages was built by the Vulcan Iron Works. It is a double-drum, steam-driven, link-motion, balance-valve, direct-acting friction-hoist. The friction band-brake and reversing gear are handled by auxiliary air engines. The horsepower is 300. The hoist for skips (Fraser-Chalmers) is a double-drum, link-motion, reversing friction engine, with post-brakes, which, as in the case of the man engines, are handled by auxiliary air-engines, as is also the throttle. The sheaves for skips are 12 ft. diam. and the sheaves for cages are eight feet. The ore is crushed by one large Gates rock-breaker, then passes over a coarse grizzly, the oversize going back to the rock-breaker; the three products are fed separately from bins to three picking tables. The compressors supply air to 21 Sullivan drills (3⅜-in. cylinders), and to 7 or 8 Mack drills used in the adjoining Josie mine, to all the underground pumps enumerated above (except the electric pump on the 900-ft. level), the saw-mill engine in the timber shed, the hoist at the Josie mine concentrator, the air-lift doors at the station ore-bins in Le Roi, two fire-pumps on the surface, a Snow duplex 14 by 8 by 12 and a Worthington duplex 14 by 8 by 12, the auxiliary hoisting engines, the whistle signals at the hoist, machine shop, and for blowing smoke in both Le Roi and Josie mines.

Twin-Beam Air-Pump.

The maximum efficiency of a condensing apparatus can only be obtained by observing certain laws and conditions. The injection of cooling water must be provided in a certain determinate quantity, depending upon the temperature of the water and amount of steam to be condensed. If the injection water is liable to be quite warm at times, the air-pump and condenser must be proportioned to suit the condition of highest temperature of the water, as, for instance, in tropical countries. If, for example, the water obtainable is liable to reach 80°, the quantity of injection water relative to the steam to be condensed will be as 55 to 1, assuming temperature of discharge from air-pump to be 100°, while, if the water is 60° only, one-half that quantity will do the work.

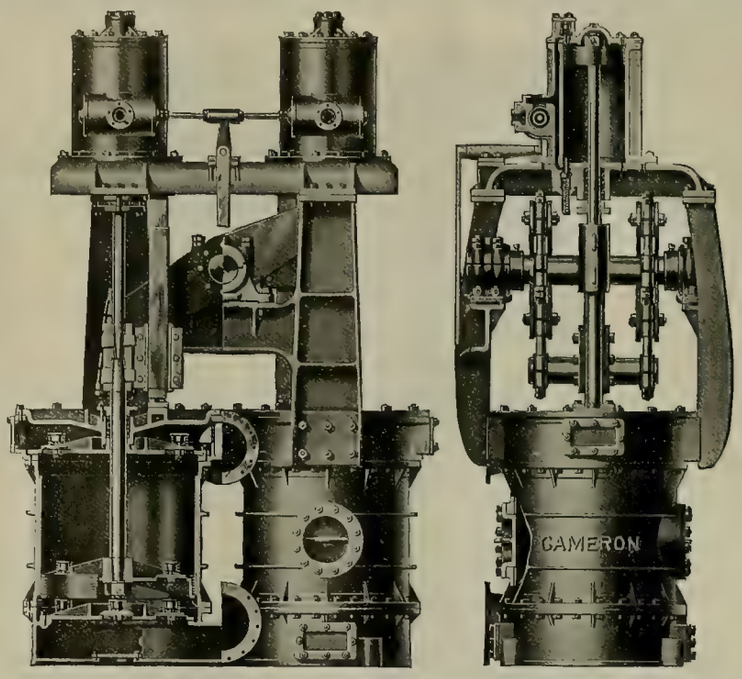
The size of condenser or condenser-volume is not an important factor, as when an ultimate association of steam and injection water is accomplished, that is the only thing to be considered. But in the jet-condenser system the size of air-pump is of the utmost importance. With the ordinary horizontal, direct-acting machine, the speed of piston should not exceed 70 ft. per min., and the pump should be so proportioned that the speed will be less, rather than greater. As the amount of air which will enter the condenser is an uncertain quantity in actual service, the exact size of the air-pump cannot be positively determined, but it should be amply large to provide for the contingencies likely to arise, due to leakage and imperfection, which permit of the admission of an undue amount of air from the atmosphere.

From the above it will be apparent that the size of condensing apparatus cannot be determined from the engine horsepower, unless it is known the number of pounds of steam per horsepower the engine uses. In other words, the size can only be determined from a knowledge of the pounds of steam of a certain pressure to be condensed. And no matter how the problem is presented, no accurate calculations can be made unless sufficient data are given to permit of its resolution into the weight of steam and its temperature. The temperature, however, is generally assumed, as under ordinary conditions the temperature of exhaust (which bears a fixed relation to its pressure) is very nearly the same.

We are indebted to J. J. Herrick, mechanical engineer of the New York dock department, for information pertaining to the relative size of engines and condensing system in use on each of the five new municipal ferry-boats, which are now in daily operation between Manhattan and Staten Island. The motive power and equipment of these boats are of the most modern design. They are propelled by twin steel screws, driven by two inverted, direct-acting, two cylinder, compound engines, having crank-shafts bolted together, and with steam cylinders 22½ in. and 50 in. diam. by 30-in. stroke, and develop over 4,100 h p. at 157 r. p. m., but in regular service only 3,000 h.p. is developed.

The main surface condenser, which takes care of the exhaust steam of these engines and auxiliaries, contains 1,884 tubes ¾-in. outside diam. by 12 ft. 4½ in. long, having a condensing surface of 4,513 sq. ft. The vacuum gauges show ordinarily 26 in., but sometimes 27 in. The centrifugal circulating pump has 12-in. suction and discharge, and is driven by a 9 by 9-in. vertical engine, making 160 r. p. m. The approximate amount of steam condensed by the engines per hour is about 18½ lb. per horsepower, thus, as stated before, for the present service 3,000 h.p. is developed, making steam consumption about 55,000 lb. per hour.

The Cameron vertical twin-beam air-pumps installed on these boats are used to pump the condensed exhausted steam from the main condensers, and deliver it to the feed-water tank or overboard; being of ample size, with 10-in. steam cylinders and 22-in. air cylinders, with 18-in. stroke. The illustration shows plainly the construction of these pumps, both the steam cylinders and vacuum cylinders being shown in section.



Sectional View of the Cameron Twin-Beam Air-Pump.

A RECENTLY printed description of a new instrument for surveying deep bore-holes contains a compass, plummet, cameras, and electric light, the whole connected with a small adjustable clock, so that the light may be turned on for a given period after the apparatus has been lowered into the hole. It has been used in surveying a number of holes in South Africa and has proved satisfactory. Both dip and deviation are recorded by means of photographs of the positions of both a plumb-bob and a magnetic needle at any desired point in the bore-hole. The photographs are taken by means of two small electric lamps lighted by a time contact.

The Prospector.

Enquiries sent to this department are answered free of charge, submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

The white rock marked Goldfield Special is rhyolite.

The ore from Organ, New Mexico, is magnetic iron oxide (magnetite).

The rock from Tombstone, Ariz., marked A. G., is limestone, partly crystallized.

The samples from Raymond, Cal., are: No. 1, ilmenite (titanic iron) in quartz; No. 2, a silicious mica-tourmaline schist.

The white earthy sample from Dayton, Nev., marked C. T., is diatomaceous earth. The diatoms are very minute, and there are but few well-defined forms.

The rocks from Capitola, Cal., are: No. 1, largely composed of calcium magnesium pyroxene, diopside; No. 2, principally quartz. The dark mineral contains no zinc.

The rock from Steins Pass, New Mexico, is a feldspathic dike rock. It shows no metallic mineral, but is as likely to be associated with ores as any other eruptive rock.

The samples from Poker Flat, Table Rock, Cal., is a much altered dike rock containing pyrite and mispickel (arsenical iron sulphide). It probably also contains gold.

The samples from Telluride, Colo., marked J. L. F. are: No. 1, not shale, but a much altered feldspathic rock stained with iron and manganese oxides; No. 2 is what may be termed an iron alum, that is iron sulphate with small amount of aluminum.

The rocks from Iron Springs, Idaho, marked C. S. M., are all decomposed and iron-stained dike rock, excepting E, which is chert with some iron sulphide. This rock E is probably a silicified portion of the feldspathic material of which the other rocks are composed. 'E' should be assayed for gold and silver.

All the rocks from Joy, Utah, marked R. W. (excepting No. 2) are silicified feldspathic dike rocks stained by iron oxide. No. 2B is essentially quartzite, being composed wholly of grains of quartz. There are no indications of copper in any of these rocks, nor that they are from a gossan covering a copper deposit. There is a greater probability of their containing gold.

The samples from Aguascalientes, Mexico, are No. 1, quartz with iron sulphide. The blue mineral is only an incrusting film and has most of the physical properties of talc. No. 2 is quartz and chert with the sulphides of iron, zinc and lead. The galena is easily recognized by its cubic cleavage; the pyrite by its color, and the zinc blende by its brown streak; and its evolving sulphureted hydrogen on application of a drop of hydrochloric acid.

A Curious Accident.

Our Australian contemporary, the *Bendigonian*, gives an interesting account of a sensational accident at Mr. George Lansell's Needle mine, at Bendigo. We quote:

The driver, Thomas Woolcock, was engaged on the afternoon shift bailing water. A few minutes before 6 o'clock he was raising a tank of water in the western compartment. When the tank was nearing the surface, Woolcock applied the steering gear wheel to shut off steam. Although the wheel turned, the spindle did not have the necessary effect on the valve. The engine continued to work, and the tank was now perilously near the surface. The driver persisted in his efforts to shut off steam by turning the wheel tighter and tighter, but to no avail. He then realized that there was something wrong with either the valve or the spindle. Just then the tank ran up to the wheels, and the rope was severed by the thimble. Fortunately the patent safety grippers on the tank acted, and the tank remained suspended immediately under the bar in which the thimble is placed. All this time the engine was working under full steam. When the rope was severed, it flew off at a terrific rate. The protecting iron railings around the wheels were torn down, and the rope entering the engine-house made a large aperture in the corrugated iron. A rafter situated immediately over the drum was smashed. The drum kept revolving, and the rope coiling and recoiling, was striking the floor behind the drum and to the right of the driver with great force. In a few seconds a large hole was beaten in the floor, and the pipe immediately above it carrying the steam from the boiler to the engine was also repeatedly struck by the loose rope. Had that pipe been broken, a serious explosion would undoubtedly have occurred. In the meantime the tank in the eastern compartment had gone down into the cistern a little below 1,300 ft. Woolcock, when he saw the rope severed, had the presence of mind to run out of the engine-house and turn off the steam by the valve over the boilers. However, as the boilers are situated some distance from the engine-house, this operation took some little time. With the steam shut off, of course, the machinery stopped, and not too soon, for the tank in the eastern compartment was again ascending. If unchecked by the shutting off of steam it, too, would have gone to the wheels. The manager arrived, and an inspection was made of the machinery.

It was found that the pin and nut on the valve spindle had come off. This prevented the driver shutting off steam. The nut was some time later found in the piston-box, with the threads considerably worn. No blame was attached to the driver for the occurrence. The management considers him to be a very competent man. This was borne out by the cool and effectual way in which he acted subsequent to the breaking of the rope at the wheels. There were men engaged in the shaft sinking, but with the presence of the cistern there was practically no danger. No damage was sustained to the engine, the only requirement being the replacement on the spindle of a new nut and pin. Repairs were effected, and subsequently the men were hauled up from below. The loose rope on and about the western drum was straightened out, and a few shillings should cover the damages.

UNDERGROUND WATER.—The highest recorded velocity of underground water has been discovered by H. C. Wolff, of the department of mathematics of the University of Wisconsin, in the course of an investigation which he carried on in Arizona recently. The rate of movement of underground water in gravels near Tucson he found to be 144 ft. in 24 hrs., while the highest previously rated by observers was only about 100 feet.

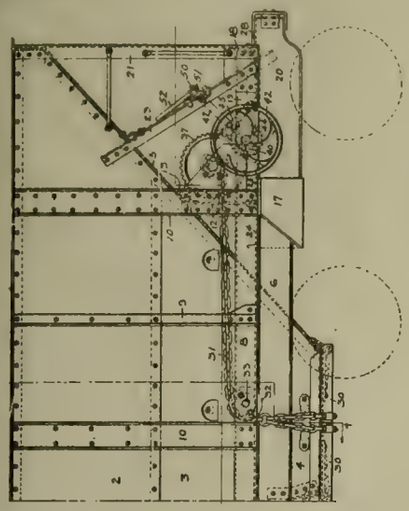
THORITE, a thorium mineral, occurs in square prisms, but also massive and compact; is brittle, of distinct cleavage, conchoidal fracture, of vitreous to resinous lustre, and has a hardness verging between 4.5 and 5, and a specific gravity of 4.4 to 4.8. A nearly related mineral is orangite. The color of the two minerals is sometimes orange or brownish-yellow (orangite), but sometimes brown inclining to black (thorite). The streak is light orange to dark brown, and the splinters, when thin, are nearly opaque. Thorite is known to occur in several localities in Norway. Thorium dioxide, when heated before the blowpipe, remains infusible; it imparts no tinge to the flame, and gives a colorless borax bead. It yields no characteristic reaction with cobalt nitre. The minerals containing thorium have become commercially valuable, as they serve for the preparation of the mantles of Welsbach's incandescent lights.

Mining and Metallurgical Patents.

PATENTS ISSUED MARCH 13, 1906.

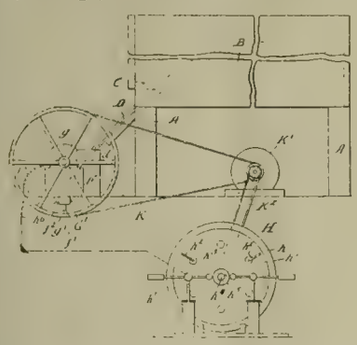
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

ORE-CAR.—No. 814,273; A. Christianson, Butler, Pennsylvania.



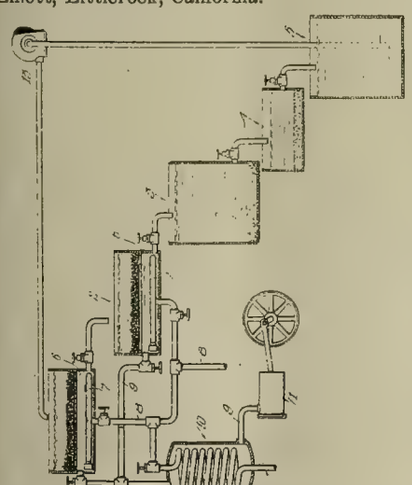
In a railway car, combination of longitudinal sills, body-bolster having vertical web projecting above sills, an end sill connected at its ends to car sides, draft-beams connecting end sill and body-bolster, and gusset-plate resting on draft-beams and secured thereto and being provided at its ends with flanges secured to web of body-bolster and to end sill, gusset-plate being triangular and having its wider end toward body-bolster.

AMALGAMATING PROCESS.—No. 814,814; H. A. Thomas, Chicago, Illinois.



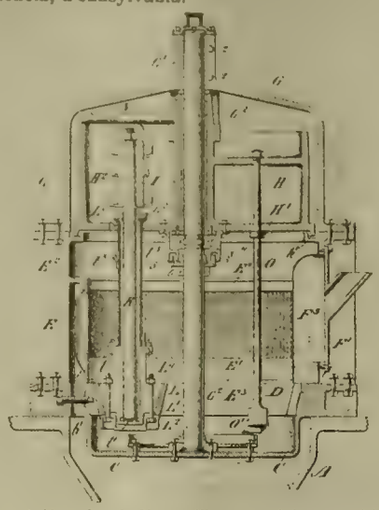
The dry amalgamating process herein described consisting in insulating a body of liquid mercury, charging it electrostatically, and feeding through it a thin sheet of pulverized ore, whereby precious metals are amalgamated or removed from ore and mercury completely freed and separated from tailings.

PROCESS OF COPPER SEPARATION.—No. 814,836; A. Elliott, Littlerock, California.



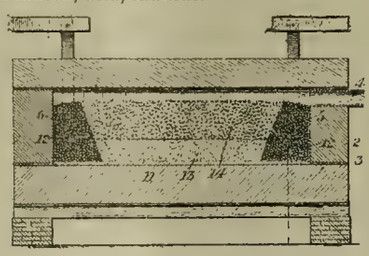
Process of separating copper from oxidized ores which consists in leaching ore with hot, non-acid solution of ferrous sulphate, passing air through solution during operation of leaching, separating solution from residue, and precipitating copper from solution by means of iron, thereby regenerating ferrous sulphate for repetition of process.

PULVERIZING MILL.—No. 814,961; E. H. Hurry, Bethlehem, Pennsylvania.



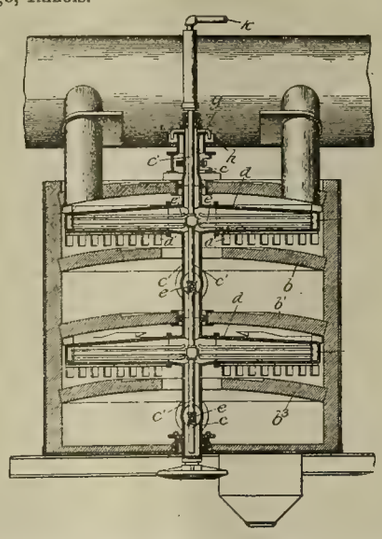
A centrifugal grinding mill, comprising combination of horizontally arranged grinding ring having an upwardly and outwardly flaring grinding face, downwardly extending roll shaft, driver above ring with which roll shaft is connected, and roll with downwardly tapering periphery, connected with roll shaft and traveling around ring.

ELECTRICAL SMELTING PROCESS. — No. 814,050; W. M. Johnson, Iola, Kansas.



The smelting process, which consists in interposing between charge containing low-grade ore, and furnace-wall, charge containing high-grade ore, thereby protecting wall from the action of low-grade ore.

ROASTING-FURNACE.—No. 814,238; T. F. Sheridan, Chicago, Illinois.

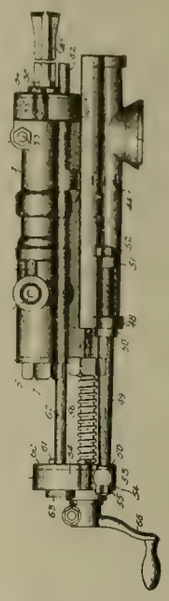


A roasting-furnace, hollow upright shaft, horizontally arranged hollow rake-arms attached thereto and communicating with interior thereof, supply-pipe in the shaft, branch pipes in hollow arms communicating with supply-pipe, branch pipes having terminal openings within the hollow shaft.

EXTRACTION VESSEL.—No. 814,940; C. M. Chamberlain, Lead, South Dakota.

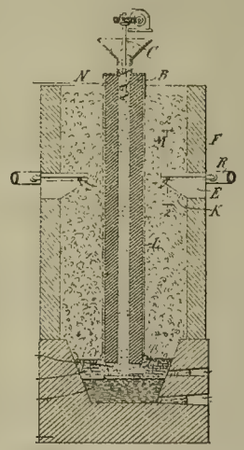
An extraction-tank comprising substantially air-tight vessel, tray mounted therein, filter-bed in tray, conduits communicating with tray above and below bed and discharge-gate extending across vessel opposite tray.

ROCK-DRILL.—No. 815,299; J. G. Leyner, Denver, Colorado.



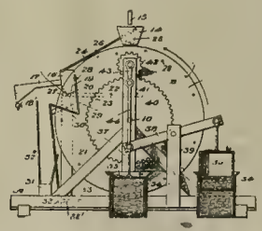
In rock-drilling engine, cylinder, supporting-shell in which cylinder is mounted, piston-hammer reciprocally mounted in cylinder, drill-bit loosely supported in cylinder, in the reciprocal path of piston-hammer, polygonal surface on drill-bit, gear loosely mounted on drill-bit and rotatably journaled in cylinder, gear in mesh with drill-bit gear, rod slidably keyed to gear, a feed-screw operatively connected to cylinder and shell, and means including gearing connected to feed-screw and rod for simultaneously rotating rod and feed-screw.

PROCESS OF SMELTING IRON ORE. — No. 815,016; P. L. T. Heroult, La Praz, France.



In the smelting of iron ore, process which consists in feeding ore, introducing carbon at base of charge while protecting it from action of carbon dioxide generated by smelting operation, whereby mixture of carbon monoxide and carbon dioxide is formed of gradually increasing richness in carbon dioxide as gases rise to point at which reduction of ore substantially ceases, and introducing oxygen at such point to further oxidize carbon monoxide and increase heating effect in furnace.

SAND AND SLIME SEPARATOR.—No. 815,095; D. J. Kelly, Salt Lake City, Utah.



In sand and slime separator combination with pulp-supply, of revolubly mounted wheel having side-delivery settling-compartments into which pulp is successively delivered, means for holding the wheel against movement, means for automatically releasing wheel, and means for imparting to wheel a step-by-step movement.

Special Correspondence.

LONDON, March 14.

At the third ordinary general meeting of Violet Consolidated, Ltd., held in London last week, the chairman described the progress made with regard to the extensive programme of development laid down at the previous annual meeting. The property of the company consists of 683 claims, two stands, 17 bewaasplaatzen (depositing sites) and two water-rights. There are 60 stamps, with cyanide works. Of the nominal capital—£500,000—there has been issued and paid up £396,762. The identity of the Botha reef with the Main reef has been established by an exhaustive geological survey of the property. With the help of 500 Chinese laborers who arrived in August last, active work has proceeded on the company's property in conjunction with the two neighboring mines—the West Rand Mines, Ltd., on the north, and the West Rand Consolidated Mines, Ltd., on the southwest, comprising together an area of 2.000 claims. The Botha reef, dipping south from the West Rand mines, extends into the Violet ground at a depth, proved by a borehole, of less than 1,900 ft. The Battery reef, outcropping throughout the property, with a strike northeast and southwest, has in the past been opened up to a considerable extent, and its great width will render it capable of being mined under the most favorable and economic conditions. Since the arrival of the coolies, the two shafts existing on the Violet property have been unwatered and they are to be connected by a long underground drift, thus opening up a considerable quantity of reef. The chairman said the company possessed ample funds to carry the work to a stage which would enable a better judgment to be formed as to the value of the reefs, provided the Government's present policy did not interrupt the supply of unskilled labor and render abortive the work already carried out. As a proof of the facility formerly enjoyed by holders of Rand mines for putting up prices, the £1 shares of this company, although with only a partially developed and non-producing mine, were dealt in at £3⅜ in 1904. They have since suffered in the general collapse, and now stand at £1½.

A cablegram from the East Rand Proprietary states that the Angelo Gold Mines, Ltd., had started crushing with their own mill of 40 stamps, which would be increased during the present month to 110 stamps.

The arrival in London is reported of a 21-oz. gold nugget, found about 15 miles southeast of Bulawayo, 62 ft. from surface—believed to be the largest yet unearthed in Rhodesia.

Under the auspices of Japan, it is thought the mineral resources of Korea, which are believed to be important, will be available for development and exploitation. There is a rumor that Messrs. Wernher-Beit are interested in a concession valued at £3,000,000 sterling.

British exports for February again show an expansion in iron and steel and "manufactures thereof," the values in this department at £2,912,000 being £754,222 higher than a year ago and £846,268 higher than two years ago. Our pig iron exports last month were 81,083 tons comparing with 56,508 and 47,184 tons, respectively, in the corresponding months of the two previous years, a fact which indicates that in Germany, the United States, France and Italy, in particular, the manufacturers' demand has progressed even more than in this country. The exports of machinery, at £1,890,911, are also £419,445 higher than a year ago.

According to the annual report of the Egyptian Mines Exploration Co., Ltd., some of the properties in which the company is interested are promising well. At Atallah a linear extent of at least 1,000 ft. of vein has been proved on its dip, down to 410 ft. The veins reach a maximum width of 47 in. and a maximum value of 10 oz. 2 dwt. per ton. At Eridia a large amount of work has been done and Mr. Alford reports the vein width as good throughout with a maximum value of 3 oz. 12 dwt. per ton. At Semna the company has by far the largest masses of goldbearing quartz yet met with. Crushing commenced on the Um Rus mine in March 1905 and the total for the year is 6,161 tons, the average yield being 17.24 dwt., allowing for 3.30 dwt. in the tailing. In this case the maximum value is not stated.

The Nile Valley Co., Ltd., has now carried through its scheme of reconstruction by including the provisions of Section 161 of the Companies (Winding up) Act 1862, under which, in the case of dissentient shareholders, if the arbitrator gives more than the price the shares realize in the market, the new company must pay the difference.

The Indian Glenrock (Wynaad), Ltd., is a remarkable example of perseverance in the domain of company finance. It is the result of a perfect maze of re-constructions, extending over a period of 20 years or more. The company possesses interests in Western Australia and New Zealand, but operations are now being centered on the property in the Wynaad district. After the expenditure of much money on low-grade propositions that were unprofitable, some rich specimens have been unearthed in shallow workings opened by the natives in former times. These rich finds are described as coming from outside the walls of an enormous reef worth by itself about 7 dwt. per ton. Cables concerning the discoveries have begun to raise the hopes of patient shareholders. The latest news is to the effect that rich ore has been struck in Kurrumber No. 3 and that samples from the whole width of the lode—three feet—pan 10 oz. per ton!

The Burma Development Syndicate, Ltd., was formed in 1903; with a capital of only £5,000 it secured three square miles of tinbearing land, 15 sq. miles of other mineral ground and nearly 1,000 acres of ground suitable for rubber planting. A remarkable account of the company's explorations was given at a meeting recently held to receive the agent's report. He stated that the property appeared to be one of the most extraordinary combinations of lode and alluvial tin that has been discovered in any part of the tin-producing East Indies, with natural facilities such as water-power, timber and a good climate to assure cheap production. Reports from various experts including Mr. T. W. Hughes, superintendent of the Geological Survey of India, go to prove that there is a bonanza in sight. The discoveries made by the Syndicate confirm the experts' opinion that the granite zone at Maliwan is extensive and rich in tin. Samples taken from the outcrop of a body of ore enable the agent to estimate that 10% tin oxide may be expected, which should yield 60% metallic tin. He also finds, in prospecting the alluvial ground, that the tin-bearing gravel runs from 18 in. to three feet in thickness under an over-lay of loam from three to six feet thick, and that the gravel contains more than 50 lb. tin oxide per cu. yd. It is proposed to form a company to work the properties of the Syndicate with a capital of £150,000, of which £75,000 is to be working capital. The lode-tin alone is estimated to yield about 22% on the capital, apart from the alluvial tin and rubber plantation.

A descriptive article in the *Times* contains some particulars of the Cerro Muriano copper mines, situated about 18 km. northeast of Cordoba, in Spain. The area of the 314 claims is about 776 acres. Here the Romans had a mining camp, which, judging from the extent of the remains, must have been of vast size. The shafts still left are some 700 ft. in depth. As for the modern workings, these consist principally of two main shafts, the object of the company being to continue the sinking of one of them—San Rafael shaft—to open up the lode and prove its value below the old workings. Mr. William Frechville, chairman of the company, in a recent report, stated that the material taken out whilst driving the 212 and 250-m. levels yielded, with the primitive dressing appliances available, at the rate of two tons of 18% copper ore per square fathom. He said the conditions generally were favorable for cheap work, and on a scale of 100 to 200 tons per day, an ore of about 2½% copper would pay. According to the latest reports, the mine is opening up well at different points. At the 820-ft. level west from San Rafael shaft, the whole face is lode-matter for the full width carried—six feet—with an average estimated value of 4½% copper. Other workings from this shaft and from the Victoria shaft are yielding similar results. The nominal capital of Cerro Muriano Mines, Ltd., is £235,000 in £1 shares, of which £85,000 is purchase price; Messrs. John Taylor & Sons are the managers.

A decision has been wrung from the Inland Revenue authorities in the case of Esperanza, Ltd. (Mexico), which has an important bearing on the assessment for income tax on profits of English companies holding shares in American mining companies. The Inland Revenue claimed the tax on the whole of the profits realized by Esperanza, Ltd., from dividends on its shares in the American (Esperanza Mining) company. Against this claim it was contended that Esperanza, Ltd., should be free from liability to pay income tax upon such profits of Esperanza Mining Company as are not remitted to the United Kingdom, in virtue of the English company being an investing or merely shareholding company, not carrying on or managing the business of the American company. This argument has been allowed to hold good and consequently the American shareholders (who own the bulk of the shares) of Esperanza, Ltd., will not suffer the annoyance and loss in having their portion of the profits mulcted for English income tax. To maintain this position, English and American companies so situated must take care to keep each company's accounts quite distinct and apart, and the English company's board and officials have to conduct their business and correspondence so as to show that they do not exercise any power of control over the American company or its officials and property; in effect, the management must be in America and not in England.

A thrilling account has just reached London of a Mexican bullion hold-up, rivaling in romantic incidents a story from the pen of James Fenimore Cooper. The author of the narration is Mr. John B. Farish and the bullion convoy was from Dolores mine. The attack took place about noon of February 15, at a point west of the Pajarito pass, some three or four hours' ride from Santo Tomas, on the Chihuahua Pacific Railroad, below a camp which the robbers had established on the mountain above, with the object of watching the movements of the bullion convoy from the mines. From this camp the approach of the escort could be observed for a considerable distance; and below it, on either side of the trail, breastworks of stone had been erected, partially concealed by branches, behind which the bandits were stationed. These breastworks, of which there were three, commanded a slope up which the convoy was compelled to move slowly; and it was evidently the intention to place them in such a manner that the space from the first to the last would include the entire bullion train in its usual marching order. The convoy entered the trap as calculated by the robbers, and when conductor Smith, riding at the head of the column, came abreast of the last barricade, which was very close to the trail, a man with his face partially masked suddenly showed himself behind the wall, and fired at him from a distance of about eight feet. The ball struck a cartridge in Smith's belt, cutting a piece out of the head and throwing out the primer, unexploded; and after passing through his belt and clothing it cut a deep gash about four inches along across the abdomen. Although his horse reared and bolted, Smith managed to draw his revolver and fire at the robber as he passed; but whether his shot took effect is not known. Meanwhile the other bandits had opened fire on the escort, two of whom were killed and one shot through the body, probably at the first discharge, while the last three fled for safety and gained a low ridge, which shielded them from flying bullets. Smith's best man, Francisco Torres, was probably not hit at first, as he was seen to jump from his horse and take to the thick brush for cover, with the intention of making a slight detour and reaching his chief, who was ahead; he died fighting, for his body was found a short distance from the trail, his rifle clutched in a death grip and the attitude of the body showing that he was hit while taking aim. As soon as Smith was able to restrain his frightened animal, he dismounted and ran back to the shooting, his intention being to cut out of the bunch the mule carrying the money, which he succeeded in doing after exchanging shots with one of the robbers who came out to meet him somewhat above the trail. Having secured this mule and finding that none of his men appeared to aid him, he struck out with the mule and his horse, and, after proceeding a short distance, cut the pack from the mule, took out the money and started on a gallop for the town of Cocomorachic, which he reached in about three hours, faint and weak from loss of blood. Tracks near the trail show that one of the bandits must have followed him closely on foot until he was beyond reach, it probably being expected that he was so badly wounded that he would fall within a short distance. Closely following the bullion train, and endeavoring to reach it in order to travel more safely, came a widow *en route* to her ranch on the Rio Verde, with her six-year-old daughter, and a single *mozo* as escort. Her party reached the spot at the very moment when the firing began, and she jumped from her horse, caught up her child and ran for safety. Her *mozo* was shot through the hand while endeavoring to draw his revolver, and joined her in a cave in the ravine below, where they remained hidden all that afternoon and the following night, until they were found by the searchers. The convoy men who escaped having reached Santo Tomas, a posse was formed, telegrams sent to the authorities for aid, and a start made for the scene of the attack, which was reached at four o'clock in the morning. Here another posse was found, from Cocomorachic, which had set out on learning from Smith what had happened. Part of the men pushed on to Cocomorachic after daylight to find Smith, who was reported in a dying condition, and the remainder started to follow the trail of the robbers and gather up the freight dropped by the convoy. Smith was found to be resting comfortably, however, and was left at Cocomorachic until brought into Temosachic by a Green Gold-Silver coach, when he received proper medical attention. The posse returning from Cocomorachic was joined by a force of *rurales* and the next day the trail was taken up and followed until lost at Tejolocachi, on the Chihuahua & Pacific Railway. It was regained shortly after, however, and as the authorities displayed great energy and willingness, strong hopes are entertained that the bandits will be caught soon. This tragic occurrence and the awful explosion in the French collieries at Courrières, near Lille, on Saturday last, involving the loss of over a thousand lives, are reminders that the mining industry has its martyrs and heroes equally with religion and war.

BUTTE, MONT., March 27.

Heinze's La France Copper Co. has taken up the option on the Lexington group, at Walkerville, Butte district. The group consists of the Louise, Angelo, Lexington, Wild Pat, Wappelo, Atlantic and Allie Brown claims and the Allie Brown millsite. There are less than 23 acres in the group. In years gone-by these mines were heavy producers of silver, but when the silver ore was practically worked out the mines were shut down by the French owners, without further exploration and development. Two years ago F. A. Heinze, who had developed his Corra mine up to the end lines of the Lexington, demonstrated that there was a copper vein running through the Lexington at considerable depth below the old silver workings, and through an agent in New York secured an option on the properties at a comparatively small figure. He subsequently organized La France Co. to take over the Lexington and Basin Reduction Co., which has now been done. It is surmised that La France will eventually become an asset of the United Copper Co., which has been left without property since the sale to the Butte Coalition.

The biggest new mining enterprise in the Butte district, in point of holdings and prospects, is the Butte & Bacorn Copper Mining Co., organized by Butte and Pittsburg capitalists. The company is a close corporation and the public is not asked to participate in its chances. Fred W. Bacorn, a Butte mining man, and 40 Pittsburg capitalists, including bankers, steel men and coal and iron men of that city, are the company's backers. The Pittsburg men have put up $10,000 each as working capital, and the company has purchased mines and locations to the amount of 245 acres, and has options on 225 acres more lying just north of Walkerville, at the extreme northern limit of the old Butte district. The ground owned and under option is nearly half a mile in width and about two miles in length, east and west, along a copper lode 150 ft. wide. There has been practically no development on the lode, but mining men, including a number of Amalgamated engineers and officials, are favorably impressed with the indications and prospects. The Butte & Bacorn has just started three shafts at different points on the property and is placing hoisting plants, air compressors and other necessary and modern machinery. One shaft has reached a depth of 80 ft. and is in good copper showings. The two other shafts are down about 65 feet.

The Cable Consolidated Mining Co., another corporation organized by Mr. Bacorn and his Pittsburg associates, is a holding company for the Cable Lease Co. and Cable Mining Co. The last named was the owner of the Cable gold mines, 50 miles west of Butte, which produced $4,000,000 in gold from workings near the surface. The Cable Lease Co. has been working the mines for several years, taking out a large amount of gold. Last week it shipped one bar worth $35,000. The mill is running 16 hours daily on good ore, and the company has 600 tons of ore ready for hoisting.

The Butte & London Co., now controlled by the Venture Corporation of London, is making rapid progress in sinking a shaft on the Greendale, going down at the rate of five feet daily and having reached a total depth of 200 ft. The directors of the Butte & London held a meeting in Butte a few days ago and confirmed the action of the stockholders in selling control to the Venture Corporation. Three new directors were elected to represent the Venture. They are Frederick W. Baker, president of the Venture; John C. Montgomery, of New York, American representative of the Venture, and LeGrand Smith, a London banker. The Venture Corporation was authorized to appoint a register and transfer agent in New York. They have $50,000,000 invested in gold and silver properties in Colorado, Mexico, California and Australia. Its entry into the Butte field is its first investment in copper.

Some of the richest copper ore mined in the Butte district is coming from the mines of the East Butte

Copper Mining Co., which are worked by lessees. A vein of copper glance has been opened in the Simon and the same orebody was cut in the Lassan, east of the Simon. The ore hoisted runs from 60 to 70% copper. The vein averages in width from two to four feet. The Yankee Boy is also mining rich ore. The East Butte company is making good progress on its enlargement of the No. 1 shaft. When that shaft is completed the company will mine the ground below 300 ft. and the lessees will probably be permitted to continue operations on the upper levels. They are paying a royalty of 25%, which is more than the average net earnings of Butte mining companies. Only two companies in the district last year showed better earnings than 25% net. Copely Amory, of Boston, a director of the General Electric Co., has spent a week in Butte and familiarized himself with the East Butte properties. William A. Paine, one of the large stockholders of the company, will be here during the first week in April.

The Anaconda Co. is hoisting ore from the big vein recently opened at 2,400 ft. At that point the same vein that was cut on the 2,200, several months ago, has been opened, and drifting is in progress. Reports are that the vein on the 2,400 is not so large as on the 2,200, but richer. The drifting shows it to run from 8 to 20 ft. wide. A portion of it, from two to six feet wide, runs 40% copper, and the entire vein at the crosscut will average about 15%. The Anaconda is now hoisting between 1,100 and 1,200 tons of ore daily, of which 250 tons are first class, averaging better than 20%. The general average value of the ore of the Anaconda Co. is between four and five per cent.

The Raven Mining Co. is making regular shipments of 50 tons of ore daily running from 5 to 7% copper. The rich body of ore found in the south vein, opened by a crosscut from the north vein drift on the 1,200, is continuous throughout a drift 250 ft. long east and west. The orebody is from two to six feet wide. The same vein has been cut on the 1,500 level and drifts there are in ore, indications in the east drift being that the same body worked on the 1,200 level will be soon encountered. The company is not stoping at present, the ore taken out being that mined in drifting and blocking. The north vein on the 1,500 level will be reached by the crosscut within a week, and then the output will be increased without stoping. On the 1,200 a number of raises on the north vein are in good ore.

SALT LAKE CITY, March 27.

March will close on a dividend record for Utah mines to the amount of $286,500, to which the Silver King contributed $100,000; Daly-West, $108,000; Consolidated Mercur, $25,000; Beck Tunnel Consolidated, $15,000; Grand Central, $12,500; Victoria, $10,000; Swansea, $5,000; Uncle Sam Consolidated, $5,000; Sacramento, $5,000, and Utah (Fish Springs), $1,000. The United States Smelting, Refining & Mining Co. has posted a dividend of 87½c. for payment in April.

The ore shipments from Park City last week aggregated a total of 4,805,460 lb.; the Silver King sending out 2,000,460 lb.; Daly-West, 1,145,000 lb.; Daly-Judge, 880,000 lb.; ditto, zinc middling, 632,000 lb.; Kearns-Keith, 123,000 lb.; Jupiter, 25,000 pounds.

Ore is being received by the Garfield Smelting Co., which is constructing the new plant near the old Garfield Beach bathing resort. Bin capacity for 25,000 tons has been provided. These bins will be filled preparatory to blowing in the first unit, about June 1.

The past week has witnessed the completion of an important work at the Daly-Judge mine at Park City, when connection was made between the 1,400 and 1,500 levels in the western portion of the mine's workings, where the principal exploratory work has been conducted during the past two years. The primary purpose of this raise was ventilation, but ore was encountered the greater part of the distance, the width of the vein being several feet. On the 1,500 one shoot of high-grade ore was encountered which has been followed 170 ft. with its limits still undetermined. The width of the body has not been ascertained beyond the limits of the drift. A sampling of this orebody was undertaken by a Salt Lake engineer during the month; he reported the ore to run $40 to $45 per ton. The management expects to have the bonded indebtedness cleared up by July 1. The company, even at the present rate of production, will be in position to pay dividends long before the close of the present year.

There have been a number of damage suits filed against smelting companies operating in the Salt Lake valley. In the latest one Oscar J. and Abram J. Reese are plaintiffs who ask for $37,449, alleged damage to their farms and crops during the three past calendar years.

The Colorado Mining Co., with headquarters at Provo, has filed an amendment to its articles of incorporation, increasing the capital stock from $125,000 to $200,000.

Conditions continue to improve as the shaft at the Silver King Consolidated, at Park City, goes down. It is now at a depth of 1,100 ft.

The stormy weather of the past few weeks will delay the starting of the Century mill in Park Valley mining district. The management is unable, owing to bad roads, to get in a supply of fuel. The condition of the mine is reported as encouraging by the manager, P. W. Madsen, of Salt Lake City.

The annual report of the Horn Silver Mining Co. just issued for the year ending Dec. 31, 1905, shows that the Beaver county property of this company produced 3,464,007 lb. lead, 6,639 lb. copper, 6,035,553 lb. zinc, 104,231 oz. silver and 335 oz. gold. The total receipts from ore sales aggregated $173,267.51, the same coming from 4,733 tons of crude ore averaging $12.44 per ton, 8,445 tons of first-class zinc ore at $10.87 per ton, 1,349 tons lease ore at $13.97 per ton, 5 tons copper ore at $31.12 per ton and 258 tons concentrate at $13.88 per ton. The total cost of ore extraction was $62,745.31, or an average of $3.85 per ton. The concentration costs were $3,111.50, $2.13 per ton, and the basis of concentration was 5.2 tons into one. Dividends to the amount of $80,000 were paid and the year closed with $39,415.91 cash on hand, $10,000 in call loans and no liabilities.

The initial shipment of ore from the Little Bell mine, at Park City, will be marketed in a few days. Recent important developments have caused the stock to almost double in price in the local market, during the past week. The company is capitalized for 300,000 shares and the Daly-West Mining company owns one-fifth of it. The annual election of the shareholders resulted in the election of Solon Spiro, president; Sidney M. Bamberger, vice-president; Herman Bamberger, treasurer, and J. B. Bean, secretary, all of Salt Lake.

The shipments from the Tintic district last week amounted to only 178 carloads, owing to the bad condition of roads. The shippers and amount being: Bullion-Beck, 8 tons; Ajax, 4; Carisa, 4; Dragon Iron, 3; Eureka Hill, 12; Grand Central, 9; Brooklyn Con., 1; Beck Tunnel, 8; Centennial Eureka, 54; Eagle & Blue Bell, 9; Gemini, 17; Lower Mammoth, 4; Ridge & Valley, 5; South Swansea, 1; Uncle Sam, concentrate, 2; Uncle Sam, crude, 4; Victoria, 4; May Day, 5; Swansea, 4; Scranton, 2; Yankee Con., 3.

The annual meeting of shareholders of the Utah Consolidated Mining Company has been set for April 17, at the offices of the company in New York.

A shipment of lead ore from the Butler Liberal mine, of Bingham, marketed a few days ago, averaged 55 per cent lead.

A large body of copper ore has been cut in the Gold Hill property, in the Clifton district, Deep creek, in Tooele county, on the 100-ft. level. The assays are fair. A drift is being run from the 150-ft. level.

Negotiations are still pending between Peter Haack, of Los Angeles, and some of the larger shareholders of the Honerine, through which Mr. Haack hopes to get control of the mine. While it is not known positively whom he represents, the supposition is that the negotiations are in the interest of F. A. Heinze and associates. Mr. Haack has made overtures to the Black Diamond and New Stockton companies for a control of the mines owned at Stockton by those corporations.

The holders of the option on the City Rocks mine, at Alta, have made another payment on the purchase price, leaving still due, $100,000.

For a consideration of $2,250, the United States Ozokerite company has purchased 160 acres of ozokerite claims in Spanish Fork cañon, Utah county.

Power drills have been installed at the Montezuma property, at Bingham, and the working force has been increased. Peter Porter, of Salt Lake, is manager.

The total ore and bullion settlements reported at the close of last week by the banks of Salt Lake City aggregated $428,500.

The Michigan Copper Co., backed by Michigan capital, is operating in Beaver county. A shaft is down 200 ft. and will be continued to the 400 or 500-ft. level. Ore carrying low copper values has been encountered. J. M. Reynolds, of Salt Lake City, is manager.

DENVER, March 25.

For some time past an association of individuals has been acquiring property and preparing plans for the construction of a reservoir, to impound the waters of the St. Vrain. It is their intention to incorporate under the name of the Lake St. Vrain Co. Under the preliminary organization, considerable property has been acquired and plans have been matured, covering an undertaking of great magnitude. The reservoir site will cover the town of Lyons, Boulder county; the proposed dam is to be located about one mile east of the town, and if the present plans are carried out, the town, containing about 700 inhabitants, will have to be moved.

The plan and section maps of the dam show the following dimensions: The dam proper rests upon a foundation 200 ft. wide, extending 12 ft. below the ground-level, which level lies at an altitude of 5,300 ft. above sea level. The superstructure, commencing at the foundation, is 180 ft. wide and 250 ft. high at high-water mark, to which line it is battered to 20 ft. wide; above the high-water line there will be a parapet of 8 ft. base and 10 ft. high, making the total height of masonry 272 ft. or 260 ft. above the ground-level. The length on ground-level is 1,300 ft. and the extreme length at the top of the dam is a little more than 2,350 ft. The longitudinal sections shows a straight line with the ends of the dam carried 12 ft. into solid ground. The silicious red sandstone abounding in the vicinity will be used in the construction of the dam. The association has secured a large acreage of sandstone, including the Mathews red sandstone quarries at Noland, three miles distant from the dam and connected with it by railroad. A perfect block of sandstone from these quarries, 9 in. thick, 8 ft. wide and 25 ft. long, was laid in front of the main entrance of the Colorado building, at the Chicago World's Fair.

It is the intention of the company to establish a central power station at the dam and utilize the most approved machinery and methods in quarrying, transportation and construction. If the company meets with no hindrance to its plans, it will commence construction of the dam this summer. It is proposed to quarry and lay 1,000 cu. yd. of stone per day. The dam will cost between $2,000,000 and $3,000,000, and will require several years to complete. The storage capacity of the reservoir will be 8,000,000,000 cu. ft. of water, about double that of the new Croton reservoir of New York. Referring to page 44, 'Water Supply and Irrigation Paper No. 74,' Series 1, United States Geological Survey, 'Water Resources of Colorado,' A. L. Fellows, St. Vrain creek at Lyons, we find the data for 11 years—April to November of each year—giving the mean annual run of water at 10.7 in. from a drainage area of 209 square miles; equivalent to 1.18 second-feet per square mile. The St. Vrain, therefore, furnishes excess water, not used in irrigation, when stored for use, to cover about 400,000 acres with a sheet of water three inches deep, twice a year, which is sufficient justification for a project of even greater magnitude than that of the Lake St. Vrain Company.

Development work on the Maple Leaf mine, at Sillsville, Gunnison county, has been carried to a depth of 250 ft., and levels have been driven 80 ft. long from this depth, disclosing a lens of ore eight feet thick, said to carry 1½ oz. gold per ton. The mine has nearly 900 ft. of levels developing an ore-shoot 200 ft. long by 3 ft. wide, valued at from $6 to $12 gold per ton. The stamp-mill, of 35-ton capacity, is nearly completed and will commence to run on ore about May 1.

Mining Summary.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

ALASKA.

Authorities in Seattle have issued a statement claiming the gold output for the present year in Alaska and the Yukon will amount to $32,000,000 in round numbers. Of this amount it is estimated that the Tanana section will lead with $14,000,000.

The London Perseverance Mining Co. according to W. H. Hampton, is planning the development of its quartz properties in the vicinity of Juneau. This mineral zone is two miles long and 200 ft. wide, the ore running from three to four dollars per ton. At present it is developed to a depth of 900 ft. by a tunnel, 2,500 ft. in length, but the company is planning a tunnel 10,000 ft. long, which will run through the mountain and make it possible to deliver ore at tidewater. Five companies will combine to drive this tunnel.

ARIZONA.

(Special Correspondence).—A number of the large lead-producing claims in the Huallapi mountains, in Mojave county, are to be worked this spring and summer. Arrangements have been perfected by a number of claim owners to handle these ores. A small milling plant will be put in at the Enterprise mine for custom work on low-grade ores. The higher grades of lead ore will be shipped.

The vein in the Climax mine, in Union Basin, will within a few days be cut. The drift will drain the mine of water. In the bottom of the shaft, which is 170 ft., there is a body of ore which is said to average $100 per ton.

Three hundred men are now employed at the Helvetia mine, in Pinal county. The smelter, which has just blown in, is making a trial run. It has been found necessary to make extensive repairs to improvements at the mine, as the plant has run down during the five years it has been idle. The ore-bins are badly warped and will have to be replaced by new ones. Fine ore is being taken out from the 800 level.

The Cyrus Noble Co., at Searchlight, Nev, has purchased from the Quartette Mining Co. its entire electrical equipment, which includes a 40-h.p. engine and a 30-kw. dynamo. The plant, when installed, may furnish lights to the town. The work of enlarging, timbering and improving the shaft is still in progress. The mill will be in operation soon.

The new hoisting plant at the Weedin mine, at Pittsburg, is in operation and doing good work. The shaft, which is one of the best in Pima county, has attained a depth of 310 ft. The bottom is in silicious lime rock, slightly impregnated with iron and copper sulphides. Water, to the amount of 100 gal. in 24 hours, has been encountered.

Phœnix, March 26.

Cochise County.

At Paradise, it is reported that a rich strike has been made one-half mile north of that town. The ore is telluride of gold and chloride of silver running into the thousands. The lucky prospector was Fred Bernoudy. The vein is three feet wide, and at a depth of 40 ft. an assay gave returns of 42½ oz. gold, 2,680 oz. silver and 30% lead. Men have been put to work and shipping of ore begins at once.

Mohave County.

At Stockton Hill the contractors drifting in the Banner mine have opened up a body of rich ore 3½ ft. wide, showing wire and massive native silver. Quite a number of tons of this ore were taken out, but owing to the fact that there is no ore house at the mine in which to store it work was stopped on the drift. About 100 ft. from the breast a raise is being made and stopes opened. As soon as the mill is in readiness the mixed ore will be concentrated and shipped.

Thomas Brayil, part owner of the Lucky Boy mine at Chloride, is getting out a carload of rich silver ore for shipment to the local smelter. A new strike was made on the 300 level owing to a cave which uncovered an ore shoot running $700 in silver and an ounce in gold per ton.

Yavapai County.

Five miles west of Prescott, and near Thumb Butte, H. C. Malloy recently sunk a shaft 30 ft. on a claim he purchased from J. W. Mullican, and is sacking the ore taken out for shipment to the Humboldt smelter. When Mr. Malloy's attention was called to some ores that Mr. Mullican had found on the property, he had an assay made which gave good results. He purchased the claim and staked three other claims on the same vein and commenced to sink in a 10-ft. hole. At the bottom of his shaft there is a solid body of sulphide ore 2½ ft. in thickness, which averages $75 per ton in copper, gold and silver.

Work which was temporarily suspended on the Pine Mountain group in the Walker district, has been resumed with W. J. Casey as foreman. —— The installation of machinery on the Mark Twain, near McCabe, is completed, and the management expects to have a large force at work in a few days.

The American Girl group of ten claims and millsite have been sold by L. I. Fletcher to T. N. Barnsdall, of Pittsburg. The group is situated east of the Agua Fria river, and two miles from the Humboldt smelter, in the vicinity of the Baumann Copper Company camp, in a locality traversed by a number of large iron and schist dikes, along ore deposits that have been exposed by surface workings carrying copper and gold.

Wm. Thiesing has sold his property to the New England Copper Co. Mr. Thiesing had developed the ground himself and has over 500 tons of shipping ore on the dump and 2,800 tons blocked out in one of the claims, the average value of which is $18 per ton in gold. In addition to this, there are 900 tons of tailing at the mill, which carry $9.30 per ton, which can be treated by the cyanide process. The properties included in the trans-

fer are divided by Turkey creek into two groups. The one on the west side, consisting of five claims, includes the gold mine, upon which the greatest amount of development has been done. The group on the east side, 12 full claims, has not been developed, but has a good surface showing in copper and gold. The Golden Belt claim, one of the west-side group, is opened to a depth of 300 ft. by a number of incline shafts and by more than 2,000 ft. of drifts and crosscuts. The deepest shaft on the east side group has only been sunk to a depth of 60 ft. The sale includes the mill on the ground, all the camp equipments, houses and other improvements.

CALIFORNIA.

Amador County.

The Galena mine, near Volcano, is working 14 men eight-hour shifts, under the management of John McCuch. Machine drills are employed, and the work of sinking is being continued. The Volcano mine is another property three miles from West Point. Sinking is going on and it is to be worked more extensively. A body of ore has been struck in the tunnel, and the 10 stamps of the mill are running. The mine employs 25 men under the management of C. J. Newman. The total rainfall in the district has been greater than in any year since 1902—to the present date, 33 inches.

Calaveras County.

Work has been resumed at the Deep Gulch mine, owned by F. W. Suessdorf, near Rich gulch. They are running both day and night shifts and the outlook for the future is good. A tunnel is in 150 ft. and a winze is being sunk where the north and south veins meet, 75 ft. from the surface. The ore assays $37 gold per ton.

Near Mokelumne Hill, the Easzy Bird mine employs 12 men, and they keep 10 stamps dropping on ore that plates $3.60 per ton, besides yielding a ton of sulphurets per day, which nets $50 per ton. The mine is worked through tunnels, the vein averaging 10 ft. wide of milling ore.

At the Nelson ranch, two miles from West Point, two men are working a ledge. Also at the extension of the Blue Bell mine, on the South Fork, two men are extracting ore. On the Middle Fork, at Moreheads, work is being prosecuted with good results. Geo. Cougdon is working the Yellow Aster, and George Chick and James Thompson have a good showing on the Middle Fork. T. Carlton is running his 5-stamp mill on rock taken from his mine on the South Middle Fork of the Mokelumne river.

El Dorado County.

It is reported at Greenwood that a 10-stamp mill is to be built on the Vivian mine, near that town. A vein six inches wide at the surface has widened in 60 ft. to 4 ft. wide.——A nugget worth $600 was found by John Hipp near Georgetown a few days since in digging around the roots of a dead tree.

Kern County.

Charles Taylor, superintendent at the tungsten mines, near Randsburg, says they are working 22 men and taking out high-grade ore. The railroad company has put in a spur and they load cars at the mine. Shipping to the Barstow mill has proved a success and they concentrate five cars of ore into one. The first week in April they expect to ship two cars of high-grade ore direct from the mines to Liverpool or to Germany. They now call the new camp and station Atolia. A new Fairbanks & Morse gasoline hoist has been ordered for the mine and is now on the way.——George and Harry Swartout and B. B. Summers are taking rich ore from the Minnehaha, and expect to have a milling soon. The Minnehaha lies just west of the Yellow Aster mines, and some of the richest ore ever taken out in the camp came from this mine.——Everything is going smoothly at the Yellow Aster mines and mills, where they are crushing 500 tons of ore and working 175 men. The ore is at present running well.——In drilling for water near the wells in Goler wash much difficulty has been experienced in going through the boulders which compose all the drift after getting a little below the surface, and the work is slow. They have one well down over 400 ft. and struck the water 30 ft. before reaching that point. They expect to continue at least another 100 ft. The new deep well east of Johannesburg has never been thoroughly tested, as it is a difficult job to pump that depth, but the company has nearly completed arrangements to test its capacity, which will be done inside of two weeks.

Nevada County.

Forty-five students of the mining college of the State University at Berkeley will go to Grass Valley April 10 to visit the mines of that district for a week or so. They will be accompanied by Professor Lawson, and while there will go underground every day.

The Champion Mines Co., of Nevada City, will start up 20 stamps of its mill. The recent strike in the Nevada City mine will furnish most of the rock for crushing, some of it coming from the Champion. A long drift has been run to reach the ore-shoot in the Nevada City, which was reached a few days ago. When the ore-body has been developed sufficiently, it is thought the entire mill equipment can be kept in continuous operation. The ore is far from the territory now in dispute between the Champion and New Home companies. The mine is making considerable water, but not more than can easily be controlled.

Plumas County.

Work on the Antlers mine, situated on Craycroft ridge, five miles from Downieville, says the *Messenger*, is progressing. The tunnel, which will cut the vein at a depth of 300 ft., is in 200 ft. and near the vein. The ledge is eight feet in width and assays from $3.50 to $6 per ton, free milling. The pay shoot is several hundred feet long and it prospects the entire distance. The mine consists of four locations and is owned by T. Winrod and J. E. Deal. The work is being done by T. E. Hayden, who has a bond on the property. The camp is one of the neatest and most conveniently equipped in the county.

Sierra County.

(Special Correspondence).—John Spellenburg, Samuel Devine and Frank Cook, of Sierra City, have sold the Bullion mine to Los Angeles and San Francisco parties. The company has incorporated, under the name of the Royal Quartz Mining Co., and they have let a contract for running a tunnel and drawn plans for a mill. The ledge is from 3½ to 12 ft. wide and mills from $7 to $12 per ton.

The Mountain mine has closed down temporarily, on account of shortage of timbers.

The Empire company, in Gold valley, has its electric plant repaired and is running 20 stamps.

The Gold Point mine is going to continue the main tunnel on the course of the vein.

Work at the Sovereign is progressing steadily.

The Tightner has installed a gasoline hoist and will resume sinking while they are driving the tunnel.

The Telegraph has bought a large Cornish pump and will resume sinking as soon as it is installed.

The Antlers owners expect to strike the ledge very soon in their crosscut tunnel.

Spaulding & Peckwith are taking out rich gravel. This is a continuation of the White Bear channel.

Downieville, March 26.

Work will be resumed at the Kelston mine and mill early in April. The main tunnel is in a mile, and the incline is 400 ft. from the face to the bottom of the old shaft through which the mine was worked years ago.

The Mountain mine, owing to the lack of timber, has been compelled to shut down.

Tuolumne County.

Last week the dam at Phœnix lake, three miles east of Sonora, broke. The wagon bridge on the Tuolumne-Sonora road and the railroad bridge were both washed away. Several mines of the vicinity were dependent on power from the lake.

Sixty men are working at the Soulsby mine at Soulsbyville.——At the Black Oak 80 men are employed.——At the Confidence the company is increasing its working force.——Over $4,000 was taken out of Dull & Co.'s Jackass Hill mining properties, near Tuttletown, last week. —— The work of unwatering the Louisiana mine, near Carters, is progressing.——At the Paymaster, work on the tunnel, under T. Knowles, is being pushed forward and many other improvements are being made.

The Grizzly mill, near Carters, is running steadily on rock from that mine and the New Albany.——At the Paymaster in Hunter cañon, work is being confined to the 400-ft. tunnel, the contract for which is held by George Bartlett and partners.

A few men were put to work in the Harvard mine at Whiskey Hill, near Jamestown, last week. Thomas Russell is foreman.

At the Lady Washington, near Carters, the new boarding-house is almost completed. A small crew of underground men is at work and others will be added when working room is made. The 1,700-ft. tunnel has to be driven 250 ft. farther to connect with the Dead Horse shaft, when the two mines will be operated together.

COLORADO.

Chaffee County.

The test recently made on the Independence ore by the electro-magnetic separators was satisfactory, with the exception that gold was not saved and all the copper was not saved, and, as the principal values are in copper and the gold values small, it is demonstrated that the ore can be handled profitably. Further tests will be made with a view to saving the gold as well as the copper, which will add about 90c. per ton to the available result.

The Jasper lessees have opened a streak of smelting ore at the heading of the drift in the 200-ft. level. A stope has been started. The streak is seven inches wide and widening.

In the Telma work continues in the drift on the Holdrege vein. In driving the tunnel a cross-vein was encountered beyond the Holdrege vein, which carries milling values in the tunnel, and when it is reached a large quantity of milling ore will probably be opened.

Custer County.

R. W. Eames and James Ryan have taken a bond and lease on the Monitor lode. The claim is said to show a streak of ore 12 in. wide, which assays 38 oz. silver per ton.

J. T. Stroehlke has leased a block of ground lying on the Bismuth, lying between the main Bismuth workings and the King of the Carbonates, and has begun work. He has an 18-in. streak of ore, samples running 53 oz. silver per ton. Phillips & Skevington have taken a lease on a portion of the Bismuth.——H. Cocking now has a force employed in putting up buildings on his copper property.——Dr. Pretson, who is operating the Bismuth mine, sent another car of ore to the smelter at Salida. ——Work on the Little Bernice is progressing. The drift at the 380-ft. level is in 50 ft., and it is expected to cut the ore found in the upper levels.

Gilpin County.

The Eureka mine, of J. C. Jenkins, one of the oldest patented properties in the county, but which has been idle for a number of years, is again in operation. Fifteen men are at work, mostly lessees. Work is confined to the 300, 400 and 500-ft. levels, where good bodies of ore are opened. On the 300 level smelting ore is being taken out that nets $80 for first class and $60 for second class. In drifting west on the 500-ft. level, a body of smelting lead ore has been opened up.——Wettstein, Fontaine & Co. have completed the erection of a whim on the Fagan claim of the Grand Army or Gunnell vein in Prosser gulch. The collar of the shaft has been raised and track put in to the ore bins. An increased force of miners is being put on, a night shift being again employed.

Gunnison County.

After lying idle for 12 years, the Denver City copper mine at Iris has been bought by J. M. McDougal of Gunnison. The last ore shipped from the property carried 17% copper. The old workings consist of a 200-ft. inclined shaft and 500 ft. of levels and crosscuts. A new shaft 50 ft. deep will be put down to reach the old one, and a new shaft-house built. On one crosscut alone there are three veins of copper ore, which measure one, six and ten feet, respectively. In another crosscut is a 19-ft. vein of zinc ore.

Dr. Louis Weiss reports his intention to erect a mill at his Vulcan mine as soon as the process for treating Good Hope ores is thoroughly tested. The Good Hope, Vulcan and Mammoth Chimney ought, when properly developed, to become some of the greatest producers in Colorado. The immense dumps have hundreds of thousands of dollars of values obtainable under modern mill conditions.

Lake County.

The Boston-Arizona mill, at the head of California gulch, is ready for operation, and ore from the Fanny Rawlins will be treated, making a high-grade zinc product and a lead-iron concentrate carrying the gold and silver. The mill will treat 20 tons daily, and if the experiment is a success the capacity may be increased to 200 tons daily. The lessees who were driven out by the fire at Mahala have resumed work. Before work was suspended 60 tons of zinc ore were being shipped daily.

San Juan County.

A few men have been employed on the Congress group in Bridal Veil basin, at the head of Blue Lake, for several months past. Work was suspended a week ago on account of the deep snows. Reese Breckenridge brought down 100 lb. ore from the property last week, which will run $700 per ton. The pay streak from which this ore was taken is a foot wide. The vein is from three to six feet wide between walls, and highly mineralized in gold, silver and lead. Besides the Congress there are three other claims in the group. P. Hanson, J. W. Hanson, P. A. Lilley and E. M. Arthur are the owners.

Summit County.

(Special Correspondence).—New incorporations are of frequent occurrence in the Breckenridge district. Besides the New Holmberg Co., organized a few days ago, are now three additional companies formed to operate here. The first is the Coyne Gold Mining Co., organized to work a group of mines on Peak 1, in the Ten Mile range. The Emma J. forms part of this group and 25 years ago was a prominent producer of silver-gold ore. This property was bought outright, patented, and the owners have allowed it to remain unworked until this new company was formed.

The Bay State Mining Co. is the title of an Eastern organization formed to work a group on the upper Blue, on the west side of the Senator mine. The local management is in the hands of Arthur Howard.

The Mons Auri Mining & Milling Co. has been formed by Mark G. Evans, of Denver, to operate a large consolidation of claims on Farcomb hill, in which is included the Wire Patch. Farcomb hill is the locality from which beautiful crystallized gold specimens have come, which have taken the first prize in numerous exhibitions, where shown, including Chicago in 1893, St. Louis in 1904 and Portland in 1905.

The main shaft of the Little Sallie Barber is now down over 100 ft. The owners expect to strike the extension of the zinc orebodies found in the adjoining property at a greater depth, estimated at 60 feet.

The Baird brothers, who are working a lease on the Dunkin mine, on Nigger Hill, have just made a 12-ton shipment of high-grade gold-silver-lead ore. They are doing a great deal of development and making ventilation connections. They expect to ship large quantities of ore the coming spring and summer.

The Reliance Dredging Co., on French creek, has carpenters and mechanics at work on their large boat, putting it in shape and renewing the worn parts of the machinery, preparatory to an early start at digging, which they hope to begin by April 1.

At Frisco, the Mary Verna main tunnel is now in 630 ft., has passed through the hard diorite and got into the softer porphyry zone. Progress is more rapid and the face is in proximity to the Copper Queen vein.

The North American tunnel is in 929 ft. and still going ahead. About 30 ft. back from the face a ledge of iron sulphide in quartz was cut, which is being drifted on.

Breckenridge, March 20.

(Special Correspondence).—Breckenridge, if all goes along as it is mapped out, is to be connected with the Moffat road by railway via Dillon and Kremenling. This project has been set on foot by local capitalists who have large mining interests here, and who have not only secured the right of way, but are backed by the necessary cash required to carry the scheme to a successful issue. The prime movers are Mr. John G. Goodier, general manager of the Abundance Mining & Milling Co., of Breckenridge; Mr. Chas. E. Oehler, a local attorney; Mr. Wm. F. Forman, County Clerk of Summit county, and Mr. Wm. Off, a Kansas City capitalist.

This new connection will bring a fair freight rate on ores and concentrate which are now being shipped at excessive rates over the C. & S. (when cars can be procured), and will also enable the bringing in of coal from Routt county at reasonable prices. The coal question in Breckenridge and surrounding points is a serious one, and while one road has the monopoly the citizens must either pay the present exorbitant prices demanded by the railway or go without.

The road will open up Montezuma and the Lower Blue camps, which are now off from railroad communication and reached by long wagon hauls. This will make both sections large and permanent producers.

Montezuma is doing good work for this time of year. Charles H. Campbell and H. N. Finotte, who are working the Fisherman mine under lease, have just opened up a high-grade lead-zinc ore streak two feet wide for 50 ft. in length. Two carloads have already been taken out, while drifting and more shipments will follow.

The Sarsfield mine has a shipment of six or seven carloads of lead-zinc ore awaiting transportation.

The Juno mine, worked by Mr. Rosengardner, has developed a solid zinc streak over two feet wide. This ore assays over 50% zinc.

The Waterloo mine has been taken over by a new company under the title of the Calumet Mining, Milling & Smelting Company.

Breckenridge, March 24.

Teller County.

The total tonnage from Stratton's Independence for

March will aggregate 3,000 tons, produced by sixty or more sets of lessees.

Lessees on block 13 of the Ajax, Mulvaney and associates, have opened a new shoot in the vein developed at the 280-ft. level of the mine. The coarse rock broken is running between three and four ounces gold per ton and the screenings 11 oz. per ton. In all there are 20 sets of lessees operating on as many different blocks of the Ajax and a majority of them are in ore.

A rich shipment of 30 tons of ore carefully sorted in three grades was sent out from the Gent and Mumm lease on block 6 of the Work company's Morning Glory claim on Raven hill last week. The ore ran: First grade, coarse rock, better than 10 oz. gold per ton; second grade, screenings, 5 oz. per ton, and third grade, or 'middlings,' 2 oz. gold per ton. The bulk of the shipment will be of the coarse rock, carrying the highest values.

Among the last week's shipments were the following: Smith & Altman, lessees on the Elizabeth Copper on Raven hill of the Doctor-Jack Pot Co., 3 cars; Morgan & Williams' lease, Cobb shaft of Moon Anchor Co., 1 car; Bruington and associates, lease on Old Gold, Beacon hill, 1 car; J. O. A. Carper lease on the Pinto, Free Coinage Co., 1 car; lessees on the Lucky Gus of the Stratton estate; Monte Cristo on Beacon hill, Hobbs & Co. lease, 2 cars; Gilpin Leasing Co. on the Jerry Johnson, 2 cars; Western Investment Co. lease on the Orpha May of the Stratton estate, 2 cars; Tunnel Mining & Leasing Co. on the Abe Lincoln in Poverty gulch, Stratton estate, car each day; Forest Queen, lease of Walsh and others, 1 car: Henry Adney on Beacon hill, Burke and associates operators, 2 cars; dump lessees on Mary McKinney, 1 car.

A three years' lease with graded royalties of from 15% to 25% has been granted to W. P. Layton, of Elkton, and A. P. Whitmore, of Cripple Creek, dated April 1, by the Bonnie Nell Co. The parties named have been contracting on the property since last October. They have been crosscutting at a depth of 170 ft. and have opened up a basalt dike which assays from $6 to $8 per ton. It is the intention of the lessees to construct a cyanide plant for the treatment of this ore.

Omaha capitalists, who recently secured a three years' lease on the Lost Lillie claim, on Copper mountain, from the Copper Mountain Gold Mining Co., will commence the sinking of a vertical shaft on that claim by April 1. A contract will be let for the first 100 ft., after which machinery will be installed and operations will be conducted by the leasing company. They also contemplate the construction of a new concentrating plant or possibly a cyanide mill at or near the shaft. The ore contains gold, silver, lead and zinc. This property, on which gold values in paying quantity were first found on Copper mountain, was classed as a shipper years ago, but has lain idle for a long period.

The Trilby, on Bull hill, is shipping heavily and the output for March is estimated at between 500 and 600 tons. The ore is of good grade and the Trilby company, it is believed, is rapidly taking the purchase price out of the mine.

IDAHO.

Idaho County.

The large and expensive mill at the Sunnyside mine, in Thunder Mountain district, which was expected to make a record in bullion production, demonstrated, after a brief run, that the ore had been greatly overestimated and the results produced are reported not to have been sufficient to pay operating costs. The mill was shut down and a new manager carried a small force on development, which was increased until a crew of 40 men is employed at present on exploring and development, with a view of discovering and blocking out pay-ore. This work is in the hands of Captain Trewick. Recent reports say that ore has been found that runs from $3 to $50 per ton.

The Dewey mine, of the Thunder Mountain Gold & Silver Mining Co., continues to be the only gold producer in the district after four years of steady development. This property made a fine production during 1905, considering the fact that its mill was closed down several months undergoing repairs. The production for the past year aggregated $67,000, and the mine and mill continue in successful operation. Part of the year's run was made from a surface quarry which yielded $7 ore that was mined and milled at a total cost of $2.20 per ton.

Owyhee County.

A rich discovery is reported on Sinker creek, 13 miles from Murphy, on the Silver City stage road. In the early days thousands of dollars were placer mined from the little gulch extending a mile in a northwesterly direction from Paul's station. Many unsuccessful efforts were made to find the ledge or ledges supplying this gold until last fall, when E. T. Clark, noticing the gravel piles along the bottom of the gulch, began an investigation, with the result that he found a seam not thicker than one inch on the surface to be the source of the deposit. He has now opened the ledge on the pay shoot by numerous open cuts extending over 600 ft. in length. At each place he has attained a depth of seven to ten feet, and in each he has at the bottom 10 in. of ore running from $50 to $200 a ton in free gold, while the porphyry gangue has a width of about four feet. The ore is rich in galena, and yet the gold is free milling. A late assay shows the presence of bismuth in one place. The vein is a fissure, crossing the country rock. The granite below the foot-wall is white and barren, while that above the hanging wall is heavily mineralized. The ledge has a dip of 45°.

Shoshone County.

(Special Correspondence).—The Hecla Mining Co. at Burke has declared a monthly dividend for March of $70,000, bringing the total dividends to date to $600,000. Of this amount $240,000 were declared last year, and thus far $90,000 this year. The 2,000-ft. drift being driven on the 900-ft. level, the engineers say, is within 50 ft. of the ore shoot, which on the 600 level has been found to be rich, and from which dividends are being derived.

Spokane, March 24.

The Grizzly Bear fraction, Butte, Anaconda, Bearpaw, Silver Bow, Silver Tip, Independent, Washington, Wheeling and Salem mining claims have been transferred to the Bear Mountain Mining Co. The claims lie on Beartop, adjoining and directly east and north of the Beartop Mining Co.'s ground. The group reaches the summit of the Bitter Roots. It is to be explored by a long tunnel, work on which is to be commenced as soon as the incorporators get down to business. All the owners are residents of Missoula, except Mr. Manley.——Mr. Clark says he will run a tunnel, and that prospecting is only in its infancy in the Silver City district, and that a few years more will serve to discover many lodes as valuable as have ever been before found. ——The Monitor mine, south of Saltese seven miles, is the only property in that section of the Cœur d'Alene which has shipped largely the past year. Last fall about $20,000 worth of high-class copper gold ore was marketed, operations being ended by Cœur d'Alene parties taking a bond on the property for $200,000. Since that time a strike of seven feet of solid chalcopyrite carrying gold has been reported, but no attempt will be made to ship again until the snow goes off sufficiently to make the road passable for heavy hauling. In the meantime, the mine is being put into such shape that extensive and continuous operations in development and stoping may be possible. The shaft, now down 300 ft., is being enlarged to double compartment and newly timbered. Adjoining the Monitor, and on the same vein, is the Richmond, which has good chances of making a producer.——The Flynn Group Mining Co., at Black Bear on Cañon creek, is driving a crosscut tunnel to tap the extension of the Black Bear Fraction Mining Co.'s ground. The latter company owns a group of claims east of the Helena-Frisco mine, which covers the faulted sections of the Frisco vein, they being the Gem, Frisco, and west end of the Black Bear. The tunnel is large enough for double track. The vein on the surface is marked with boulders of iron oxide.

R. de B. Smith of Anaconda has bonded the Tamietti placer mines, near Dry creek, in the Cœur d'Alene district, to Eastern men for $150,000. The placers are among the most important in the State. Mr. Smith will be general manager. The company will take up the bond in three payments. After the second payment the company will be in complete charge of the property. At present the owners are working them while the new company is engaged in having roads constructed and otherwise improving the property.

Washington County.

The Idaho Placer Mining Co., Ltd., is to resume operations. The dredge and machinery is in good condition. The property of the company is situated at Old's Ferry, a few miles west of Weiser, on Snake river. If the trial run proves successful another and larger dredge will be built.

MONTANA.

Fergus County.

An accident at the Barnes-King mine, near Kendall, occurred last week when the gear wheel on the hoist broke in several pieces, while the engineer was hoisting ore. One piece struck the chair on the platform, shattering it. Another piece struck the wall above the head of the engineer, A. C. Dilly, and fell back, striking him on the shoulder and leg, and bruising him painfully. Mr. Dilly threw on the brake, and the skip hung up on the safety catches a little above the 100-ft. level. The hoist will probably be shut down until a new one can be shipped from Anaconda.

The Queen Mining Co., controlled by the Foleys, will put down the shaft on that property itself, instead of having the work done by contract. In addition to this, the company will do some diamond drill work on parts of the ground not previously explored.

Granite County.

Superintendent F. G. Wagner, of the Albion Copper Mining Co., of Princeton, reports resumption of work at the Tussle mine, near Royal. On March 1 work was suspended at the Tussle mine and Carl Bergstrand, representing the original owners, ordered everything shut down because the Tussle company had failed in its agreement to sink the shaft to a certain depth by that time.

The Senate group of mines, situated in the Moose lake country, has been bonded to a man named Silliman, who is in possession of the property. The Senate group was located 12 years ago and is owned by Thomas Leary and several other Anaconda parties. Considerable development has been done.

J. P. Dunn & Co. are shipping ore of high grade from the Lincoln group to Philipsburg, from where it is sent to the smelter. The wagon haul is about 30 miles. The same company is engaged in overhauling the Berrin quartz mill and in a few weeks it will be started up.

The Moose Lake Mining Co. has men running a tunnel and drifting on a vein at the present time, but in a few weeks a large force will be put at work. This property adjoins the Lincoln group and has a large vein of good milling ore.

Many Anaconda people are interested in the mines in that country and there is probability that a lot of development work will be done there during the coming summer.

Lewis and Clark County.

Eighteen miles north from Helena, on the copper lode known as the Helena Quartz Mining group, owned by C. H. McKinney and J. Hamlin, some months ago a lease and bond was given to D. Millner, of Helena. It is claimed that this property was at one time a shipper of gold-silver-copper ores to Freiberg; but as most of the result was absorbed by excessive charges, it was shut down and almost forgotten. There is a 50-ft. crosscut tunnel and nearly 400 ft. of drift on the lead. On taking over the property, Millner and a helper re-timbered the old works, and, when 78 ft. in, while setting a timber in the supposed foot-wall, it occurred to him that it was only a false wall. A crosscut was made, and in 18 in. Millner found a parallel lead, which Mr. McKinney says runs higher in gold alone than the combined former values in the three metals.

Missoula County.

W. K. Edwards, superintendent of the Iron Mountain Tunnel Co., has secured men and machinery to operate the properties. He will work 35 men during the summer. Mr. Edwards says the tunnel will be run 5,000 ft. and will tap the old shaft at a depth of 1,750 ft. It will require from 15 to 18 months to complete the tunnel. At this point a station will be cut and a hoisting plant installed underground to sink a shaft, where, it is said, there is a shoot of ore 4 ft. wide and 550 ft. long. The proposed work will cost $75,000.

NEVADA.

Virgil G. Bogue, vice-president and chief engineer of the Western Pacific railroad, will ask for bids on the construction of 109 miles of roadbed in Nevada, embracing practically all the heavy work not already under contract between San Francisco and Salt Lake. The 109 miles extend from the Nevada-Utah boundary to Deeth, on the Humboldt river. The contract to be let will call for 25 miles or more of heavy rock work and all of the tunnel work embraced in the engineering plans in the eastern end of Nevada. Plans have been approved for a tunnel 12,000 ft. in length, through what is known as the Gosiute range. The prosecution of the tunnel work will be so regulated that it will be completed as early as the remainder of the line. It would be possible, if necessary, to work from four different shafts, but it is probable that not more than two shafts will be sunk, thus permitting the excavation of the tunnel to proceed on six headings at the same time. The construction work between Deeth and the Nevada-California boundary is all of comparatively light character, and for this reason it will not be placed under contract right away. Work is to be pushed on the construction of the line east of Deeth, and it is expected that large construction forces will be working in Nevada this summer. Construction work in California has been progressing, but is retarded by continued wet weather. From 7,000 to 8,000 men will be at work with the Western Pacific construction forces during the coming summer.

Churchill County.

The people of Fairfield are reported to be picking up the boulders on the hills surrounding their camp as well as on the streets of the town, sacking them and shipping them to the smelters for the gold they contain, some of the black, grayish looking rocks giving $300 per ton. For years people passed over the country from which these boulders were gathered. It is float and until a few months ago was looked upon as worthless. Lots on the main street of the new townsite of Hazen are selling for $1,500 each and are hard to get at that price. The mining boom in the southern end of Churchill county and increased mining activity north of Hazen have caused the rise in price.

Esmeralda County.

At the Mason Valley, near Youngstown, a strike was made in the mine recently. The company has been driving a tunnel on the Dewey claim to tap the ledge seen on the surface. This ledge has been encountered in the face of the tunnel, which so far shows 18 ft. of ore, which will assay from 5 to 7% copper. The management has started a lower tunnel, which will be 1,000 ft. in length, giving a depth of over 400 feet.

Humboldt County.

A discovery of gold is reported 35 miles west of Lovelock, near what is known as Seven Troughs, in the Marzen range. The ore is in veins said to be 12 to 20 ft. wide. The country is accessible to transportation; the survey of the Western Pacific passes directly through part of the district. The existence of gold quartz in the desert country bordering the eastern slope of the Black Rock desert has long been known. Wash gravel carrying gold has been found from Rattlesnake Springs to Rabbit Hole. Borland, the Lovelock rancher, is reported to be the principal locator. Lovelock is the nearest point from the railroad, but there are good roads from other points along the Southern Pacific track, especially from Winnemucca.

Lincoln County.

(Special Correspondence).—Official statements of A. G. Wells, of the Santa Fe, and Dr. Homer A. Hansen, of the Searchlight Northern Railway, both give assurance of the construction of their railroads in the immediate future. The engineers have completed their surveys and the work of construction is assured, grading having already commenced on the Santa Fe. Searchlight and the surrounding districts are consequently feeling a wave of prosperity. Reports from the Boulder show that crosscutting is meeting with success. A large body of medium grade ore has been encountered and the company will continue this work until the Quartette lead, which is believed to traverse the ground, is reached. Copper-stained ore has been found in the workings of the Searchlight Treasurer Co.'s property, the formation being similar to that of the Duplex and Quartette, its nearest neighbors.

The Nevada Consolidated Mines, Ltd., the latest corporation to invade Searchlight district, has commenced work on their holdings, formerly known as the McGhan & McLaughlin group of 20 claims. Men are now building quarters and preparing ground for the installation of machinery. The Searchlight Parallel is prospecting the 400-ft. level to catch the ore shoot being worked on the 300-ft. level.

The Cyrus Noble is sinking for the 1,000-ft. level. The entire bottom of the shaft is in excellent ore. The new electric plant is installed and everything moving with regularity. It is unofficially announced that a dividend will be declared during April.

The Quartette has found free gold ore running $600 per ton in crosscutting on the 900-ft. level. The ledge was found where it was calculated to be, and the crosscut, in 15 ft., has not yet cut the opposite wall.

The Cyrus Noble Extension is trenching on the Nonpareil claim to find the location of the lead, which it is believed traverses this claim.

The Duplex Mining Co. is installing two new hoists and a cyanide plant to handle the accumulated 18,000

tons of tailings. This company contemplates adding 40 stamps, making it one of the largest stamp-mills in Nevada.

Le Roy Mining Co. is meeting with good results on the 200-ft. level, a body of $12 free milling ore having been encountered. The width of this body has not yet been ascertained. When the new pump arrives sinking will be continued.

In El Dorado district several new companies are starting up and meeting with encouraging results. The Black Hawk Co. is working three shifts on the main shaft. When the new 10-stamp mill is complete this company will be a steady producer. The Venus continues in ore found in the upper workings.

The bond of $50,000 on the Mountain group was taken up by Messrs. Gresh & Roberts. The new owners propose to develop the property.

The Purnell group, in Sunrise district, was bonded to an Eastern syndicate for $15,000. Good ore has been struck on the Turner group while digging an assessment hole. The ledge averages $20 in gold and silver per ton. This ledge can be traced for 3,500 ft. along the surface.

Searchlight, March 25.

The Johnnie Consolidated Gold Mining Co.'s property consists of 12 patented claims, of which the Johnnie is developed to a depth of 700 ft. Over 4,000 ft. of work has been done, opening up levels 100 ft. apart to the 700-ft. level, and exposing a large tonnage of free milling ore which assays from $6 to $20 per ton. Work is now being pushed on the 700-ft. level, where a crosscut is being run to the orebody. Each level from the 600 up to the surface has been opened north and south on the orebody, showing ore on every level to that depth. Work has also been done on the south end of the property, where shaft No. 3 has been sunk to a depth of 100 ft., with a crosscut at this level, in ore. The Minnie Mae shaft is 50 ft. deep, with a drift 45 ft. in ore. Numerous open cuts and trenches have been made on the surface on the south end of the property. The company has decided to adopt the leasing system on the south portion of the property, where the surface gives indications of sufficient value to yield shipping ore, and with the completion of the Salt Lake Railroad from Las Vegas to Tonopah, leases can be had on terms that will undoubtedly make leasing an object. The property is well situated as to water, having two springs, from which an abundance of water for milling and camp purposes flows by gravity to the mine through a two-inch pipe

The Starlight, located near the Mayflower, eight miles north of Beatty, on which a strike was made a short time ago, has been taken under option by Curtis Mann, of Rhyolite, and J. B. Campbell, of Goldfield. The owners of the property are N. S. Marks, C. E. Hancock, J. L. Gaut and W. H. Bond, of Beatty.

Lyon County.

In the Dewey tunnel on the Dyer, being operated by the Mason Valley Copper Co., the ledge shows a width of 30 ft. and has not yet been crosscut to the wall. In the last few days a foot of high-grade ore was cut in this ledge—black oxide, which carries 40% copper.

Nye County.

A strike of 18 in. of shipping ore on the Transvaal property, a half mile south of the Eastern Contact, 15 miles northeast of Beatty, is reported by E. S. Chafey. At a depth of three feet the ore was 18 in. wide and panned over $100 to the ton. It was traced for a distance of 1,000 ft. on the surface and runs direct into the Eastern Contact ground. The Transvaal was formerly owned by E. S. Chafey and George Probasco, but an interest was sold for a good cash sum to R. W. Gorrill and J. C. McCormack. The strike was made by H. Gorrill. The formation is similar to that of Goldfield.

NEW MEXICO.

Colfax County.

It is reported that the iron deposits of Iron mountain, on the western slope of Old Baldy, near Elizabethtown, are to be worked on a large scale. The ore will be shipped out of Elizabethtown over the St. Louis, Rocky Mountain & Pacific Railway in the early part of its development, but gradually plants for its reduction and manufacture will be established near the mines and in the vicinity of Raton.

Santa Fe County

Mines at Cerrillos and Golden are changing hands. Colorado men have recently been buying up zinc mines around Cerrillos. Formerly the mines carrying zinc were unprofitable, but with the improvement in mining machinery and the high price of zinc this has changed and zinc is in demand. The Keystone mill for the handling of lead-zinc ores is to start up soon. The ores in the Cerrillos district are mostly heavy sulphides of lead and zinc carrying silver, gold and copper. At Golden the Gold Bullion placer plant is being installed, and the Racine Mining Co. are preparing to work the ground. The Ora Quay Co. has bought the Perry group and intend to install machinery. J. L. Lopez, of Santa Fe, is working the San Miguel claim. The Yankee Boy is being worked by Geo. S. Morrison. The San Pedro copper mine and smelter remain idle. G. Alexander leased the Las Vegas mine from the Argo Mining Co., and Geo. Morrison and Geo. Adriana have leased a third interest in the Gold Coin claim in San Lazarus gulch to S. Brown and R. J. Brenk, of Milwaukee. At the Hagan coal mines Superintendent Sullivan says he has the mines in shape to ship 25 cars daily when the railroad comes in.

OREGON.

Grant County.

A. Glenn and W. A. Peet have a prospect on Rabbit creek, five miles from Red Boy, known as the Baby Don group of six claims. There is also a water right on Rabbit creek that belongs with the property. In developing the property 10 ledges have been exposed, all of which pan gold. On the Baby Don ledge, 200 ft. of crosscuts and drifts have been run.

UTAH.

Summit County.

Little Bell is reported to show an improving condition. Since the first strike in the mine was made several weeks ago, the orebodies have continued to open up strong, and the ore-bins contain 800 tons of high-grade ore. Workmen are shoveling the snow from the road between the Bell and the Daly-West, and shipping has commenced. The ore will net the company approximately $50 per ton.

At the Silver King Consolidated the report has gone out that gold-bearing ore, running $22 per ton, has been encountered in the shaft. The ore was found in the last one of several fissures which have been cut in the shaft since leaving the 900-ft. level. The shaft is now approaching the 1,100-ft. level, where a station will be cut and a crosscut run to tap them.

Work at the Ontario drain tunnel is going steadily ahead. The new drift, after being run 100 ft. at an angle from the main tunnel, will continue parallel with it until the cave-in has been passed.

Beaver County.

The Horn Silver Mining Co. had a surplus of $55,770 at the close of its past fiscal year, against $70,726 at the end of the previous year, being a decrease of $14,956. The manager reports that work was delayed during the entire year, owing to inability to get miners.

WASHINGTON.

Ferry County.

(Special Correspondence.)—The exhibit at the annual stockholders' meeting of the Pearl Consolidated Mining Co., operating in Republic, which was held March 20, shows that the mine is being well managed and the indebtedness steadily reduced. Considerable development was done during the past year, and the mine is looking well today. Arrangements are in progress to increase shipments of ore. A winze is being sunk on the pay shoot from the adit, and a raise is being driven from the 190-ft. level to meet it. Stoping will begin as soon as the connection is made.

Following the reports of success in concentrating at the Mountain Lion mill, the mine has again been closed down, and both miners and mill hands have filed liens for wages long past due. Lack of cheap treatment for the ore has always been a detriment to the camp, the mines being dependent in a great measure on smelters for disposal of the ore. The Mountain Lion Gold Mining Co., December 1, 1903, gave a mortgage on the mine and mill for $60,000, in favor of Albert MacLaren, who, April 17, 1905, commenced suit to foreclose and determine the lien. The present management, it is understood, has offered Mr. MacLaren a proposition to continue work in the mine, provided he will extend the time for payment of the mortgage another year. Since that, it is reported that an engineer's report has shown that in place of 200,000 tons of $10 ore previously reported as above the 600 level, there is only 10,000 tons, which would net $29,000. The company is resisting payment of the mortgage. The entire indebtedness of the company has reached $90,000.

The Ben Hur is shipping ore, as usual. The Quilp is increasing shipments to 35 and 40 tons daily. The Belcher company is reported to be pushing a raise on the Belcher vein from the No. 2 to the No. 3 tunnel. This appears to be the first step taken toward stoping since the crosscut was finished on No. 3 level.

Republic, March 25.

Okanogan County.

(Special Correspondence.)—The official report, not yet published, of the Copper World Extension Co., operating on Palmer mountain, verifies recent favorable statements concerning that property. The first ore struck on the 200-ft. level was in the south crosscut, 125 ft. from the shaft, and consisted of three feet of solid sulphide ore, carrying copper, gold and silver, and a large excess of iron; then 20 ft. of interstratified dolomite and slate, with streaks of concentrating ore. The drills broke into a solid body of iron sulphide 145 ft. from the shaft, which continued solid across 23 ft. Samples from different parts of that body assayed from 3.5 to 27.2% copper and a little gold. The first section of 10 ft. averaged 7.9% copper, and 5.84% was the average copper content of the whole 23 ft. Following that, the crosscut was driven 33 ft. in bluish white dolomite, which had been regarded as quartzite. A drill hole in the roof and another through a slip on one side of the drift, 200 ft. from the shaft, disclosed solid ore in both places. At 245 ft. the crosscut ran into ore of a different character, and had penetrated it 20 ft. at the date of the report. In this body the copper occurs in the form of chalcopyrite, carrying gold. This ore does not carry as large an excess of iron as the 23-ft. body, the chalcopyrite occurring in streaks through the gangue, and the whole mass, it is thought, can be handled by concentration. The crosscut is now in 275 ft., but no wall has been found.

A report has reached Republic of rich ore in a recent strike on the Stemwinder, at Sheridan, and ore from an 18-in. streak has been exhibited. This prospect shows four feet of shipping ore in a vein six feet wide, exposed in an open cut 30 ft. deep at the face. The vein parallels the Phil Sheridan, and the showing is 75 ft. from the north end-line of the Kismet Fraction, one of the claims of the Phil Sheridan company's group.

Molybdenite, in bunches, in a vein from 1 to 50 ft. wide, is reported to have been encountered in the Mineral Hill Mining company's property, by E. P. Wheeler, superintendent, at Conconully. A Philadelphia firm offers $100 a ton for the ore and $600 a ton for the concentrates. Three veins have been cut in a tunnel 850 ft. long, which carry gold, silver, lead, copper, and zinc, paralleling the molybdenite deposits.

Republic, March 24.

Stevens County.

(Special Correspondence).—Indiana people have taken the Orient mine, on Toulon mountain, and, after two years, work has been resumed. The property was equipped with an air compressor and a boiler. The main vein is about 100 ft. wide and carries gold, copper, and a little silver in quartz gangue. Some of the ore assayed from three to four per cent nickel. Some shallow holes, one of them 30 ft. deep, have been cut along the surface. A tunnel was driven 800 ft., intersected three or four blind veins and ran into broken ground. It will be driven to tap the main vein. A winze was sunk from the tunnel, on one of the veins, to a depth of 30 ft., and the ore ran $18 per ton, mostly gold.

The Abe Lincoln, near Rock Cut, has a vein of gold-bearing quartz 2½ ft. wide, opened by two shafts, 32 and 61 ft. deep, respectively. It has been idle for a long time, but the company contemplates re-opening it.

Colville, March 25.

Metalline camp, on the Pend d'Oreille river, is again attracting attention to its low-grade lead properties. L. P. Larson says his plans are not completed, but he expects to build a 500-ton concentrator on the river, near the big falls. The problem of getting in the plant and taking out the concentrate is not difficult. He has been negotiating for leases on various properties and there should be no difficulty in getting 500 tons a day.

WYOMING.

Carbon County.

It is reported that the Penn-Wyoming Copper Co. will resume operations on the Ferris-Haggarty. J. Manson, former underground foreman, will take charge of the work. Work will be commenced with a small force, which will be increased as spring opens. Development will keep them busy until ore can be taken to Encampment over the tramway.

Frank O. McCormick has opened up a property on North Fork and is showing specimens of gray copper taken from a depth of 10 ft. in his claim.

There has been a lot of work done on the Charter Oak, near Saratoga, since last September. Manager Hassett has built a shaft-house 28 by 40 ft., also a headframe, installed two 50-h.p. boilers; a 20 h.p. hoist, and an air compressor, besides having sunk 45 ft. on shaft No. 2 and 300 ft. on No. 3. At the latter ore was struck in less than a foot from the surface. The shaft is now down 300 ft. on the vein.

A few days ago Mr. Hassett put men on the Iroquois, the northeastern extension of the Charter Oak, and in two days they opened up a vein of copper ore nine feet in thickness and had not reached the opposite wall. This is where the vein is cut by Calf creek. Men were also put to work on the southeastern extension on what is known as the Puzzler. A drift was run 50 ft. along the side of the mountain, exposing a body of ore. Thus the Charter Oak vein has been opened in places for two miles.

FOREIGN.

CANADA.

BRITISH COLUMBIA.

Yale District.

The Granby Consolidated Co. will increase its smelter capacity to handle 3,500 tons a day, instead of 2,000 tons, which is its present capacity. That will give an increase of about 75%. The Granby is producing copper at 8c. per pound, though some months the cost runs slightly above that figure, but it never touched 9c. per pound.

Owing to one of the Granby smelter's furnaces being out of commission a few days for repairs the past week, the output of Boundary mines ending March 24 was less than usual. Figures for the week follow: Granby mines to Granby smelter, 14,556 tons; Mother Lode to B. C. Copper smelter, 3,232 tons; Brooklyn Stemwinder to Dominion smelter, 240 tons; Sunset to Dominion smelter, 900 tons; Emma to Nelson and B. C. Copper smelter, 198 tons; Oro Denoro to Granby smelter, 396 tons; total shipments for the week, 22,790 tons; total for the year to date, 287,649 tons.

Smelter treatment for the week was: Granby works, 15,480 tons; B. C. Copper works, 4,380 tons; Dominion works, 4,408 tons; total for week, 24,628 tons; total for year to date, 299,949 tons.

It is announced that more improvements will be made at the Granby smelter this spring, the most important being the replacing of all woodwork in the plant by steel. The framework will also be replaced by steel, and the roof, where needed, will be shingled with steel shingles. It is estimated that the cost of this re-building with steel will total about $50,000.

The feature of the mines continues to be the strike in Le Roi east of the Josie dike. Nothing is known officially concerning the strike, but it is reported that the orebody has been drifted on 100 ft. on the 800-ft. level, west of the dike, and it is known that the values are good. The orebody has not yet been crosscut.

Ore shipments for the week were: Centre Star, 3,150 tons; Le Roi, 2,760 tons; Le Roi No. 2, 280 tons; total for the week, 6,390 tons, and for the year, 72,745 tons.

George Crearer, of the Dominion Copper Co., Julius Ehrlich, of Greenwood, and Karl Holman, manager of the Mother Lode mine, have bonded the O. K. mine, nine miles from Grand Forks. It is reported the price is $30,000, extending in payments over 18 months. The O. K. is up the North Fork and joins the Humming Bird. Work is to start April 1.

NOVA SCOTIA.

The Mic Mac mine, in the Leipsigate gold district, near Bridgewater, has been sold to New York people, who have incorporated under the title of the Mic Mac Gold Mining Co., with a capital of $1,500,000, divided into 300,000 shares of $5 each. The corporation is organized under the laws of the State of Maine.

MEXICO.

Oaxaca.

The Marseilles Mining Co., whose property is situated five miles southeast of Ejutla, has at the 100-ft. level uncovered a 15-ft. body of smelting silver and copper ore. ——The San Martin, bought last year by F. A. Heinze, is in good shape, and it is said this property alone could supply the new Oaxaca smelter with more copper ore than they expect to handle at the start.

Personal.

OLIVER P. POSEY is at Tonopah, Nevada.

WALTER P. JENNEY is at Manhattan, Nevada.

W. D. THORNTON, of Butte, is now in New York.

ARTHUR L. WALKER has returned to New York.

G. W. GRAY has returned to London from Borneo.

POPE YEATMAN, of New York, is in San Francisco.

H. C. BACON left Butte for New York on March 23.

EDGAR RICKARD is on his way back from New York.

ERNEST A. WILTSEE has arrived in San Francisco from Mexico.

LEO VON ROSENBERG, of New York, returned recently from Mexico.

H. H. DYER is now superintendent of the Shannon mine, at Clifton, Arizona.

JOHN B. FARISH has postponed his departure in order to see some California mines.

COURTENAY DE KALB has returned from Sinaloa, Mexico, to Mojave, California.

VICTOR G. HILLS, of Cripple Creek, is on his way to examine mines in New Mexico.

J. C. DALY, JR., of Boston, is now with the Selby Smelting & Refining Company.

CHARLES H. HOFFMAN, M. E., of Valardeña, Mexico, was at Salt Lake City recently.

JAMAIE CONNOR, of Colorado Springs, is expected in San Francisco from New York.

FRED G. FARISH is on his way to Sinaloa, after a visit to mines in Guerrero, Mexico.

W. E. DEFTY, of Phœnix, Ariz., will be making examinations in Oregon during April.

W. H. BREVOORT is in San Francisco on a visit to the mines in which he holds an interest.

THEODORE S. HOOVER'S address is care of the United States Banking Co , City of Mexico.

FREDERICK H. MINARD, of Denver, visited San Francisco on his way to Mazatlan, Mexico.

H. C. TREADGOLD has left San Francisco and is now at the Auditorium Hotel, at Chicago.

R. B. LAMB, manager of the Daly Reduction Co., at Hedley, B. C., has gone to New York.

D'ARCY WEATHERBE is engaged in investigating dredging methods at Oroville, California.

J. F. HALLORAN is now at New Orleans. He will proceed shortly to Europe on a year's holiday.

D. O. DARNELL, JR., lessee on the Little May, Cripple Creek, was in Denver several days last week.

W. HUTTON-WILLIAMS is on his way to Korea, to be assistant engineer to the Korean Syndicate.

L. W. MAYER, connected with the Guggenheim staff of engineers, was at Salt Lake City last week.

CHAS. H. ABBOTT sailed from New Orleans on his way to El Rancho, in Guatemala, Central America.

R. C. TURNER has been appointed superintendent of the Tonopah Mining Co., at Tonopah, Nevada.

CHAS. W. GOODALE and H. V. WINCHELL, of the Amalgamated Copper Company, are both in New York.

W. H. KRITZER is convalescing at San Francisco from an operation performed on the bones of his ankle.

HENRY E. WOOD and J. W. BENSON of Denver are in San Francisco, on their way to Yreka, in Siskiyou county.

H. PARK, of Salt Lake City, has been making an examination of the Sunset mine, at Deadwood, British Columbia.

JUAN FELIX BRANDES was in San Francisco on his return from Mexico, but he left almost at once for Denver, on his way to London.

JOHN HAYS HAMMOND, having got the best of a threatened attack of pneumonia, has gone to Los Angeles to recuperate.

DAVID COLE, superintendent of the concentrators at Cananea, has been investigating the concentrating practice at Bingham, Utah.

WILLIAM J. COX, general manager of the Camp Bird mine, has arrived in San Francisco to consult with Mr. JOHN HAYS HAMMOND.

LAFAYETTE HANCHETT, manager for the Newhouse mining interests, with headquarters at Salt Lake City, is at Los Angeles on a holiday.

A. F. HOLDEN, managing director of the United States Smelting, Refining & Mining Co., is inspecting the Utah properties of that corporation.

DONALD WOODRUM, manager of the Red Mountain Consolidated Gold Mining Co., has returned from the East and is at the mine in Plumas county.

F. L. UNDERWOOD, president, with W. H. THOMAS, engineer, and J. E. MCALLISTER, manager, are at the mines of the British Columbia Copper Co.

HEWITT, CARSTARPHEN & CO., mining engineers of Denver, have recently been doing professional work at Kokomo, Georgetown and Colorado Springs.

GEORGE M. SNOW, general manager of the Trapper's Flat Mining & Milling Co., Thunderbolt, Idaho, has returned to Nampa after a two weeks' trip to New York.

L. A. COPELAND, manager of the Taylor & Brunton samplers at Salt Lake, and president of the Nevada Gold Butte Mines Co., is inspecting the property of the latter in Lincoln county, Nevada.

METALS

SILVER.—Per oz., Troy: New York, (by wire), bar silver, 64¼c. per fine ounce; San Francisco, 64¼c.; London, 30d. (standard ounce, 925 fine); Mexican dollars, 50@51c., San Francisco; 50c., New York.

COPPER.—New York (by wire, average for week ending March 29), Lake, 18.62@18.75c; Electrolytic, 18.25@18.50 Casting, 18.00@18.25c. per pound. Mill copper plates, $21; bars, 21@24c. London: £81 15s. spot per ton.

LEAD.—New York (by wire, average for week ending March 29), $5.35 per 100 lb; San Francisco, pig, 5.70@6.60c. per lb.; pipe 7¼c.; sheet, 8¼@9¼c.; London: £15 17s. 6d. ₱ long ton.

SPELTER.—New York (by wire, average for week ending March 29), $6.15@6.20 ₱ 100 lb.: London, £24 15s. ₱ ton; San Francisco, ton lots, 7c.; 100-lb lots, 7¼c.

TIN.—New York, pig, $37.25@37.50; bar tin, ₱ lb., 42½c.; pig, 39c. London, £168 5s. 0d.

PLATINUM.—San Francisco, crude, $18.50 ₱ oz.; New York, ingot, nominal, $23@25 ₱ Troy oz. Platinum ware, 75@$1.00 ₱ gram.

QUICKSILVER.—New York, $40.00@$41.50, large lots; London, £7 7s 6d.; San Francisco, local, $39.00 ₱ flask of 75 lbs.

NICKEL.—New York, 48@60c ₱ lb.; ton lots, 40@47c.

ZINC.—Metallic, chemically pure, ₱ lb., 50c.; dust, ₱ lb., 10c.; sulphate, ₱ lb., 4c.

BABBITT METAL.—San Francisco, No. 1, 10½c.; No. 2, 8c.; No. 3, 7½c.; extra, 17½c.; genuine, 32½c.; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 23.50c; San Francisco, Plumbers', 100-lb. lots 19.75c.

ALUMINUM.—No. 1, 99%, small lots, 35@38c. ₱ lb.; 100 lbs., 35c.; 1000 lbs., 34c.; ton lots and over, 33c., Pittsburg. No. 2, 90%, small lots, 34c.; ton lots and over, 31c, Pittsburg.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $18.35; gray forge, $17.85; San Francisco, bar, 3½c. ₱ lb., 3¾c. in small quantities.

STEEL.—Bessemer billets, Pittsburg, $27.00 open hearth billets, $28.00; San Francisco, bar, 7c to 13c ₱ lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 8½c.; less than 500 lb., per lb., 8¾c.; in 25-lb. tin pails, ¼c. ₱ lb. above keg price; in 1 and 5-lb. tin cans, 100 lb. per case, ½c. per lb. above keg price. Dry Lead.—In bbl., 1 ton and over, 8c.; do. in kegs, 8¼c.

LIME.—Santa Cruz, $1.35 country, $1.25 city ₱ bbl.

CEMENT.—Imported, $3.00@4.00 ₱ bbl.; California, carload lots, $1.80 f. o. b. at works; small lots, $2.10 ₱ bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

LUMBER.—(Retail): Pine, ordinary sizes, $24.00@25.00; extra sizes higher; redwood, $28.00@30.00; lath, 4 feet, $4.50@5.00; pickets, $21.00;shingles, $2.50 for No. 1, and $2.25 for No. 2; shakes, $13.50 for split and $15.00 for sawed; rustic, $28.00@35.00.

NAILS.—This week the basic prices are: Wire, $1.85; Cut, $1.75. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d, Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4d and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

GENERAL SUPPLIES.

ANTIMONY.—New York, per quality, 17@18c; San Francisco, 1000-lb. lots, 16c; 300@500-lbs. 12c, 100-lb. lbs. 12c; 100-lbs lots, 13c.

BONE ASH.—Extra No. 1, 6c ₱ lb; No. 1, 5c½.

BORAX.—Concentrated, 9½c ₱ lb; powdered, 10c; fused, 25c; crystal, refined, 8c.

CANDLES.—Standard Oil Co.—Electric light, 16 oz., 11c; 14 oz., 9¾c; 12 oz., 8½c; 14 oz., 7¾c; Hotel, 12 oz., 9c; Granite (mining), 16 oz., 11½@11½c; 14 oz., 10@10½c; 12 oz., 9½@9½c; 10 oz., 8½c; Paraffines, White, 1s, 2s, 4s, 6s, 10½c; 12s, 11c; colored, 1c higher; Radiant Paraffines, 4s, 6s, 14 oz., 9½@9¾c; 10 oz., 7¾c.

CAPS.—3x, $5.50@6 per 1000; 4x, $6.50@7; 5x, $8@8.50; Lion, $9@9.50, in lots not less than 1000.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1**, 50%, carload lots, 11¾c; less than one ton, 13¾c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2**, 30%, carload lots, 9c; less than one ton. 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 23@24c ₱ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ₱ 100 lbs.; hyposulphite of soda, 3@3½c ₱ lb.; caustic soda, in drums, 3@3½c ₱ lb.; Cal. s. soda, bbls., $1.10@1.20 ₱ 100 lbs.; sks., 90c@$1.00: chlorate of potash, 12@13c; nitrate of potash, 6¾@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2½@2¾c; flour sulphur, French, 2¾@—c; alum, $2.00@2.25; California refined, 1¾@2c; sulphide of iron, 8c ₱ lb.; copper sulphate, 6½@7c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66° B, 1¾@2c ₱ lb.; nitric acid, carboys, 8c ₱ lb.

COAL.—San Francisco, coast, yard prices to dealers: Wellington, $7.50; Seattle, $6.50; Coos Bay, $5.50; Cargo lot, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, bd., $14.00; Scotch, $8.00; Cumberland, $14.00; Cannel, $8.50; Rock Springs, $8.50, long ton; Colorado Anthracite, $14.00. Coke, $11.50 per ton in bulk, $13.00 in sacks; Sunnyside, $8.50, long ton.

FIRE BRICK.—Domestic, carloads ₱ 1000, f. o. b., factory square, $25.00; soap and split, $22.50; arch and wedge, $27.50; skewback, $30.00; circle, $32.00.

Books Received.

'Electric Power Plants,' by Norman H. Schneider, is a book which will find a ready sale among those desiring a general and comprehensive knowledge of electricity and its application. It contains chapters on standard wiring; direct and alternating-current generators, motors and motor starters; testing and measuring instruments; the storage battery; the incandescent lamp, and general engineering notes; 290 pages, 203 illustrations. This book will be sent on application by the MINING AND SCIENTIFIC PRESS on receipt of the price, $1.50, in cloth: Skan & Chamberlain, publishers, 123 Liberty street, New York.

'The Structural and Industrial Materials of California' is the title of Bulletin No. 38 of the State Mining Bureau of California. The volume is profusely illustrated and covers about everything in the way of mineral that has structural value in the State, but necessarily a treatise dealing in so wide a range of materials must be somewhat superficial in its character. This bulletin will be of value to those engaged in the production of the various classes of building material, and of general interest to others. It may be had by application to the State Mining Bureau at San Francisco. Price 75c., postage 20c. additional.

Trade Treatises.

The Colorado Iron Works Co., of Denver, has issued its fourth quarterly bulletin, which contains interesting contributions by various authors, the most important being 'Modern Cyanide Plants,' by John E. Rothwell.

The H. D. Crippen Manufacturing Co., of 25 Broad street, New York, has issued Catalogue No. 10, descriptive of the box electric drill, in which is described and illustrated the box electric drill working under varied conditions, by which prospective buyers may determine the size and style best suited to their wants.

Commercial Paragraphs.

KAUL & HALL LUMBER CO. has placed an order for one 65-ton Shay locomotive, and George Cousin, Louisiana, has placed an order for one 20-ton Shay locomotive.

IN order to better handle their increasing business from the Rocky Mountain district, the Power & Mining Machinery Co., Milwaukee, Wis., have opened an office at 312 17th street, Denver. This new office is in charge of Henry F. Jurs as district manager.

THE Bertha Mineral Co. has bought a 25-ft. Hancock jig and four No. 3 Overstrom tables from the Allis-Chalmers Co. of Milwaukee. The Butte & London Copper Co. of Butte recently purchased from the Allis-Chalmers Co. four 150-h.p. boilers, with feed pumps and mine pumps, for new properties recently acquired.

MR. CHARLES C. KNAUSS, who has been manager of the Allentown Foundry & Machine Works at Allentown, Pa., since the spring of 1900, has resigned in order to accept a similar position with the Traylor Mfg. & Construction Co., whose new works for the production of mining, milling, concentrating, reducing and crushing machinery at Allentown are just being completed.

Obituary.

N. A. ARNOLD, an aged Tuolumne county, Cal., miner, was found dead at his mine on Yankee Hill, near Columbia, on the 27th inst. It is supposed he died from exposure.

C. H. ELLIOTT, of the firm of Patrick, Elliott & Camp, died at Goldfield, Nev., on the 14th inst. He was one of the prominent men in southern Nevada. MR. ELLIOTT was born in Indianapolis, Ind., in 1864. He went to Tonopah in its early days and did much in the upbuilding of that camp.

CAPT. JOHN PENGILLY, well known in the Lake Superior region as a mine manager, died in Arizona last week at the age of 53 years. He had been engaged, just prior to his death, in introducing the caving system of mining in the mines at Cananea, as practiced in the Lake Superior iron region.

Standard Books

—ON—

Mining, Metallurgy, Geology, Chemistry, Surveying, Engineering, Etc., of Technical Value to Practical Men.

Any of these books will be mailed postpaid on receipt of price to any address. Remit by draft, check or money order to

MINING AND SCIENTIFIC PRESS,

330 Market Street, San Francisco, Cal.
606 Mack Building, Denver, Colorado.
1164 Monadnock Block, Chicago.
221-24 Park Row Building, New York City.
27 School Street, Boston, Mass.

☞ If you don't see the name of book you want in this advertisement send the name of it to any one of the above addresses and we can doubtless procure it for you.

Detailed description of the following works is not deemed necessary. They are standard and the best on their respective subjects.

EDITORIAL.

OUR columns are honored with a contribution by Dr. R. W. Raymond, who writes on a matter concerning which he is particularly authoritative. As the author of a metrical version of the Book of Job, and a veteran Bible scholar on the one hand; as former U. S. Commissioner of Mines and the present Secretary of the American Institute of Mining Engineers, on the other hand, his interpretation of the many references to mining appearing in that well-known writing, entitled the Book of Job, will be read with peculiar interest.

IT is well to be told the good features of a new stamp-mill or any other mining equipment, but it is even more useful to be informed of the weak points when they are developed in the course of daily work. The splendid mill recently erected by the North Star Mines, at Grass Valley, will not lose in the estimation of engineers by reason of Mr. Arthur D. Foote's statement of certain features that have proved undesirable. Professional men will appreciate the description of the mill as given by the distinguished manager of the North Star Mines Company. We have considered the photographs so excellent as to warrant the printing of them on special paper.

PITTSBURG has become a lively mining center, of late, the sale of stocks on the curb aggregating an average of 50,000 shares daily. This does not include the regular business in mining stocks on the Exchange, where, for example, as many as 522,247 shares of Ohio-Tonopah were dealt in during January and February. The success of Pittsburg speculators in mines at Tonopah and at Bisbee has stimulated widespread interest, for many fortunes have been made out of Tonopah Extension and Calumet & Arizona. The consolidation of steel companies made millionaires vulgarly plentiful at the great coal center and has furnished the sinews of business to a large number of restless men.

DATA concerning the flow of pulp through pipe are lacking, therefore the following facts will prove useful: At the Bustos mill, at Guanajuato, Mexico, the pulp to the cyanide annex flows through a line more than a mile long, of eight-inch cast-iron water-pipe, of the bell and spigot type, with a gradient of 3.5 per cent for the first 800 ft. and 2.25 per cent for the remainder of its length. By accident, a couple of tons of almost dry 20-mesh sand was suddenly injected at the head of the pipe-line, but it was not choked; notwithstanding this severe test, it cleared itself completely in two minutes. Some of our readers may be able to quote other experiences bearing upon this subject, which is important to those in engineering practice.

MINE LA MOTTE in Missouri is an example of the profitable application of re-grinding. The dump is supposed to contain one million tons; it took 27 years in the making. The ore used to go through jaw-breakers before being crushed to eight-mesh by the old-fashioned friction rolls, without subsequent sizing and return treatment. In the mill recently erected, the dump material is re-ground with modern geared rolls, the product passing, after sizing, to Standard concentrating tables. Out of an assay-value of 72 cents per ton, there is a profit of 50 cents. The cost includes 15 cents for milling and 7 cents for smelting and refining of the galena concentrate. The mill treats 500 tons per day and it is to be doubled in capacity. Beside the lead, payment is now made for the cobalt and nickel, which formerly were disregarded in the smelter settlements.

JOPLIN, in Missouri, like Broken Hill, in New South Wales, is likely to have a dump re-treatment problem, as the existing mines become exhausted. In spite of the higher price for 'jack' or zinc-blende, which has nearly doubled in market value since 1901, there has been a decrease in the output; and though this has been slight, as yet, it is significant in itself as suggesting the approaching exhaustion of the large rich surface deposits of zinc ore. Notwithstanding the stimulus of a better metal market, the camp has fallen off in tonnage simply because the great superficial deposits, with their pockets of 5 to 20 per cent stuff, are largely worked out and the deeper mining in the sheet ground, with its three to four per cent ore, entails much higher costs of operation. The mining and milling is done for about one dollar per ton, which is good enough, but the extraction is only 60 to 70 per cent, so that big dumps have been accumulated such as will invite re-treatment. There are many hundred thousand tons of dump material that carry three per cent zinc sulphide. This is due in part to carelessness in handling rich stuff and in part to the crude milling process. The ore is crushed by jaw-breakers to ½ or ¾ inch before passing through rolls and into jigs. Tables are rarely used for re-treating slime. Facts such as these will warn those about to exploit the Broken Hill dumps with new processes, that there are other localities also which stand ready to swamp the market with their production of zinc.

Pyrite Smelting.

All practicing metallurgists will feel indebted to Mr. Lewis T. Wright for his clear treatment of the fundamental problems pertaining to pyrite smelting in its true form, that is, without adding to the furnace burden in carbonaceous fuel. While several writers have given valuable information regarding the cost of pyrite smelting, especially in a recent discussion on this subject, no individual metallurgist has contributed results based upon such laborious research, and developing scientific information of such immediate practical use. Pyrite smelting will always have its limitations, as Mr. Wright points out in his statements concerning the sulphur and iron percentage, and their ratio. The data covering the amount of oxygen required for the oxidation of pyrite to SO_2 and FeO is worthy of special notice, since it is only by a practical experiment that this point can be determined, although the quantity of air used and found necessary per square foot of hearth-area has never been brought so vividly to the notice of the average, practical smelterman as is done in the article mentioned. That hot blast is a decided advantage is emphasized by the fact that it increases the temperature of the furnace at the tuyeres, thereby quickening the chemical reactions that are taking place between the sulphur, the iron and the silica, giving greater speed to the furnace. Mr. Wright recognizes that speed is essential in pyrite smelting; and he, in common with most metallurgists, complains only of the mechanical imperfections of his application of the process.

We hope that other metallurgists will follow the lead of Mr. Wright and give similar information based on each man's particular experience, to the advancement of the science of modern smelting and the benefit of the mining industry. Such articles as this of Mr. Wright and that recently donated by Mr. E. P. Mathewson are of benefit not only to the metallurgist but also to the mining investor, for they give the information that may make for success in operations, the financial importance of which comes home even to people who have no interest in the relation of FeO to SO_2.

Re-Grinding.

It is likely that the tube-mill and the Chilean mill will be close rivals as devices for re-grinding the product of the stamp-mill. At Johannesburg, for instance, among other installations of tube-mills, two 18-ft. tubes have just been erected at the Ferreira mill; one of these was started running on January 11. This mill is re-grinding the spitzluten discharge from a 120-stamp mill that is crushing through a 22-mesh light screen and giving a duty of about six tons per stamp per 24 hours. About 250 tons of product per day is passing through the tube-mill. After leaving the tube-mill, the pulp passes over four shaking amalgamated plates, where about 60 ounces of amalgam per day are caught from the daily scrapes and from black sand caught on the plates. Before starting the tube-mill, the custom was to collect from the spitzkasten about 10 per cent of concentrate averaging 14 dwt. per ton. This was given a three weeks' treatment with cyanide, which brought the gold in the residue down to about 2.5 dwt. Now only two products are being made: Sand, representing 70 per cent of the mill-tonnage, and slime representing 30 per cent. The total residue from the company's works before starting tube-mills averaged 1.06 dwt., now they have come down to 0.6 dwt., and the manager expects to do better. The following figures in the use of shaking amalgamated plates in this mill during 1905 will be of interest: There are 24 of these plates running below the ordinary fixed plates at the batteries; during the year there was collected from these plates 16,028 ounces of amalgam; 78 per cent

of this total was recovered from dressing the plates and 22 per cent from steaming them; the total fine gold obtained was 4,808 ounces, valued at $97,941, less cost of running and maintenance of plates, namely, $5,683; that is, $92,258 represents additional profit to the mill.

In Mexico, a Chilean mill fed with a product that had passed a 2½-inch grizzly, reduced 18 tons per day at one operation, so that 20 per cent was between 100-mesh and 200-mesh fineness, while over 77 per cent passed 200-mesh. With a 10 to 1 dilution and a consumption of 12 horsepower, this mill ran for 18 months without stopping for repairs. It cost $4,000 at Pachuca and did the work described for 23 cents per ton. Chilean mills have long been in use at Pachuca, for they are legitimate descendants of the *arrastre;* nevertheless, even the Spanish engineers at that ancient mining center are using Abbé tube-mills, so that it is evident that we should soon be in possession of valuable data, secured by making trustworthy tests between the various machines employed for re-grinding.

The Coal Strike.

As we go to press, the trouble in the bituminous regions appears likely to be adjusted peaceably, but the conditions in the anthracite region of Pennsylvania are less hopeful. One reason is the plain lack of truth. There is a lot of insincerity in the arguments of both sides and the intelligent portion of the public, who is to suffer for it, is entitled to protest. For instance, Mr. David Willcox, of the Delaware & Hudson Company, and chief spokesman lately for the coal operators, denies the existence of a combination among them, which, while it may be technically true, is a manifest evasion of fact. This same representative of the operators publishes figures to show that, since 1902, the cost of mining and preparing anthracite has increased 66.68 cents per ton, or 53.6 per cent; the receipts have increased 54.42 cents per ton, or 17.5 per cent, while the balance of profit is only 12.26 cents, or 5.7 per cent more. Such statements are misleading — intentionally, of course. Mr. Willcox is silent in regard to the cost of transportation, the fact being that the profit appears on the balance sheets of the railroad companies that control the coal mines; as is reflected vividly by the stock market, for since the formation of the coal trust the shares of the Reading railway have risen from $19.50 in 1899 and $24.50 in 1901, to a maximum of $164 this year, and Lackawanna has soared from $157 and $188.25, in the years quoted, to $474.75 in 1906. The operators come before the public with a straight face and say that the price of coal at $4.87 at tidewater only yields them a narrow margin of profit, but the coal-carrying railroads, which they also control, are making money hand over fist. The railroads own or control 96 per cent of the anthracite deposits, 91 per cent being actually owned by the transportation companies. Moreover, anthracite is a natural monopoly, for outside of Pennsylvania the only known deposits of economic value are in Colorado and New Mexico, and these are of little importance, save locally. The entire source of supply is confined to nine counties in the State of Pennsylvania, the area occupied being 496 square miles. Of the nine counties, five produce 96 per cent of the entire output. The anthracite coal trust is a fact.

As an example of evasion, it is to be noted that Mr. Willcox makes no mention of small coal, which increased from 10 per cent of the output in 1890 to over 35 per cent in 1905. In 1890 a large proportion of this small coal, and in earlier years all of it, was discarded as waste; whatever is now sold is clear gain to the production; it is this small stuff that competes with bituminous coal and brings the price of anthracite down to an average that apparently shows no great increase. But the figures of tonnage tell the story. In 1890 the production of anthracite was 36,615,459 tons; in 1905 it was 75,501,503 tons.

Nor, on the other side, is Mr. John Mitchell any more reliable than the spokesman for the 'coal barons'; he is not even as representative as he claims to be. The majority of the members of the United Mine Workers are employed in bituminous coal mining; the membership is composed of employees in competing industries and engaged in more than thirty different trades and occupations; the local unions are numerically controlled by the votes of young boys, who constitute 20 per cent of the membership in the anthracite region. The big strike of 1902 was settled by the vote of a small majority of delegates; out of 811, there were 461 in favor of a strike, that is, 57 per cent only. In 1900, with a membership of five per cent of the anthracite miners, the United Mine Workers forced a disastrous strike. They now demand a uniform rate of wages, for every kind of workman, hiding the fact that this would mean a revolution; the engineer who runs a winch is to receive the same pay as the man who has a giant Corliss in his charge; it means an increase of 150 per cent in the wages of some men, and a general increase for outside men of nearly 30 per cent. Mitchell asks the anthracite operators to collect dues for his organization—for men, the majority of whom are engaged in mining bituminous coal, which is sold in competition with anthracite. He talks about a lack of contentment among men who receive unequal wages. Well, most everyone of us receives rewards and wages different in kind and amount to those that his neighbor gets, and we do not propose to turn the world upside down for that reason; a proper amount of discontent is a great spur to honorable effort. Diverse work has won different pay since the world began. Finally, as to the eight-hour day, he knows well enough that the owners of mines are willing to pay for eight hours' actual work; the Strike Commission found that under the ten-hour rule the men worked from six to nine hours, averaging about eight hours; and everybody knows that the quality and difficulty of work are factors that this time element ignores. When he comes to the demand for a recognition of his Union, he has some justice on his side; the operators are combined; they act as one. Why not the workers? The main argument that the operators can bring against the Union is that it is not completely representative and it covers the operations of a rival industry; but if the anthracite miners as a body will form an organization of their own, leaving out the bituminous districts, and if, without using threats or force, they can make their Union really representative, then the operators will have no such argument, for they have a combination which is thoroughly representative and which acts as a unit in all trade disputes. The public cannot object to such organization on either side, so long as each is held responsible for its acts, and these acts do not transgress the laws, or the intent of them.

The cry against the 'closed shop' comes with cynical humor from the mouths of the coal operators, who themselves maintain a tightly closed shop. Not only do they control the coal roads and the coal mines, but they regulate the output of anthracite to a nicety, the production being such as to enable them to get the uttermost penny out of the consumer. The public has a right to resent their championship of the 'open shop' when the operators themselves are among the worst exemplars of this form of tyranny. Certainly the dwellers in the large cities of the Atlantic seaboard know by this time how they are victimized by the coal monopoly. A pretence is made that the price paid for anthracite to the mine operators is moderate and that it is the retail dealers who rob the people. The operators are not responsible for the doings of the dealers, so they say. This is theatrically speaking. There is a retail coal-dealers' association, every member of which makes such local prices as are dictated by the association, in turn dominated by the trust; a limited membership is maintained so as to keep the business nicely adjusted. Hence the householder pays from six to seven dollars per ton when the operators are talking about anthracite being delivered at New York tidewater for $4.87. The 'open shop' is a fine phrase, but it becomes ridiculous when used by Mr. Baer, Mr. Willcox, and their associates.

It comes to this, the public is to suffer by these contests between the operators and the miners; whichever wins, the loss will be made good out of the pockets of the people and in any event the country suffers irremediable injury. Both parties have prospered during recent years; neither side merits any sympathy. The preliminary skirmishes have indicated a desire to fool the public and a hope of saddling the other side with the blame of a strike. There is no need for one. The questions at issue are largely those of fact such as can be settled by impartial investigation.

By the Way.

In a recent issue of the *Popular Science Monthly*, Mr. Alfred H. Brooks, of the United States Geological Survey, gave an interesting summary of the work done by himself and his colleagues. He says:

A decade ago the United States Geological Survey began its work in Alaska by sending a party of only three men to the Territory, whereas in the past summer 12 parties, with an aggregate membership of 50 odd men, were there engaged in geologic surveys. Even this rapid expansion is hardly commensurate with the size of the Territory and the importance of the mineral resources, the development of which the geologic investigations aim to aid. Alaska's 600,000 square miles are much spread out, stretching to a width of 2,400 miles and to the north and south length of 1,100 miles. Were this vast area, which is equal to two and a half times that of Texas, the cold, barren waste so often pictured it would be of small practical import as to when it should be surveyed. But Alaska has large and constantly growing mining interests, and it is the demand of these which has influenced Congress to increase the appropriation for geologic surveys from $5,000 in 1895 to $80,000 in 1905.

Even the present appropriation is less than 1% of the annual gold production, which has increased from $1,866,645 in 1895 to $9,300,000 in 1904, and is far from having reached its maximum. Nor does the gold production tell the whole story; the value of the copper and silver annually mined now exceeds half a million dollars, and the output of the former is rapidly increasing. There is in Alaska also some coal mining, though this industry has not yet attained its rightful importance. The Territory contains some very valuable bituminous coal fields. Prospective mineral wealth also lies in Alaska's tin ores, oil fields and gypsum beds, which have all been sufficiently exploited to indicate their probable commercial importance. The time will come when iron and zinc ores are mined in Alaska, and its immense granite areas will yield building stone to the Pacific coast.

Applied geology touches the activities of mankind at many places, but primarily, of course, in the vocation of mining. It is on the basis of geologic knowledge that soils must be classified, and this, in turn, together with the topography, determines the distribution of animal and vegetable life. In the Alaskan work of the Geological Survey, practically only the needs of the miner have to be considered. The agricultural and allied interests of the Territory are being investigated by other governmental bureaus.

The attitude of the public toward the science of applied geology has so materially changed during the last decade that its practical value is now generally recognized, though a few still remain skeptical as to the commercial importance of the results. This attitude exists partly because geology (not being an exact science) has often been brought into disrepute by dilettantism, if not downright charlatanism. Among technicians, however, it has become generally accepted that with the increase of geologic knowledge of a given region comes a decrease of the element of chance in the discovery of orebodies.

The intelligent prospector has learned that even at best his chance of success is small; but is much increased by a knowledge of the geology of a region he intends to explore. With a better understanding of the laws which govern the occurrence, origin and distribution of mineral deposits the old-fashioned, picturesque haphazard prospector, to whom it must be admitted we owe the discovery of most of our mineral wealth, will disappear, and the technician will take his place. This is probably the last field where the specialist will crowd out the man of purely practical training; but it is a substitution bound to take place in time.

A geologic survey has two objects: first, the increase of scientific knowledge, and, second, the application of this knowledge to the mining industry. The purely scientific investigations include many subdivisions and ramifications that cannot here be considered, but it will be evident, even to the layman, that, while any part of the earth's surface remains geologically unmapped, there will be a hiatus in our knowledge, which may prevent broad generalizations.

In Alaska special attention has been given to the second field of activity, namely, the application of geology to the needs of the miner. This is in part the influence of the growth of economic work in both State and Federal surveys during the last decade, but more specially because the appropriation is specifically made for the investigation of the mineral resources of Alaska. With this end in view, a score of publications dealing with the occurrence and distribution of the mineral deposits of the Territory have been issued. It has been the policy to make public the results attained while yet the investigation is in progress, in the belief that even an incomplete knowledge of the geology would be of value to the miner. With this end in view, bulletins treating of the occurrence of coal, petroleum, tin and copper have been issued, as well as many which are devoted to the gold deposits. These preliminary reports have found favor with the mining public because of their timely appearance, and have forestalled criticism of delay in issuing the more elaborate treatises.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and to give information dealing with the practice of mining, milling and smelting.

A BARREL of crude petroleum usually means a barrel of 42 gallons. One of refined oil, kerosene, means a barrel of 50 gallons.

MOST wire gauges are inaccurate owing to the high cost of accurate gauges, the price of which makes them almost unsalable.

A CARLOAD of ore is indefinite. It may mean, on the railroad, from 1 to 40 tons. Ordinarily, however, 20 tons is considered a carload.

THE specific gravity of steel is slightly higher than that of iron, being 7.854 for steel and 7.7 for iron—about 2% more for steel than for iron.

TAILING which runs upon the land of another may be claimed by the owner of the land, or he may recover damages if injured by the presence of it.

FROM 15 to 20 tons of broken rock is a fair shift's work for a mucker underground. Some, though few, may do more. It depends whether it is day's pay or contract.

AMMONIA is an antidote for many poisons, such as snake virus, etc., and also to some extent for cyanide poisoning if taken promptly. For the latter, hydrogen peroxide is better.

STAMPS weighing 1,000 lb. or more should be provided with correspondingly heavy mortars, and solid foundations superior to those which are considered sufficient for lighter stamps.

IN SPEAKING of units when referred to the occurrence of copper, lead, zinc, etc., it means 1% or 20 lb. in each ton of ore. Thus a unit of copper is worth at present New York price, about $3.75.

MINE WORKINGS can be ventilated by means of compressed air, but it is more expensive than to install proper ventilating pipes of liberal dimensions and good-sized rotary ventilating fans.

THE yellow mineral carnotite is quoted in New York at $8 to $10 per unit of uranium oxide, it containing 3 % or more. High lime content, or copper in the ore, is penalized. The presence of vanadium is an advantage.

AN AIR COMPRESSOR theoretically works up to its full capacity at sea level. There is a loss in efficiency, however, with increase in altitude. At 10,000 ft. above sea level there is a loss of 30% and at 15,000 ft. of 42 per cent.

THE Homestake Company of Lead, South Dakota, is working 1,000 stamps, each weighing 850 lb. or more. These stamps are distributed in six mills. The largest number of stamps in any of these mills is 240, the least number is 100.

ZIRKEL describes felsitic groundmass as amorphous, in thin section showing no independent contours. Its true nature is variable and not easily described. Felsite is generally considered as an intimate mixture of quartz and orthoclase.

MINING claims located prior to May 10, 1872, did not require parallel end lines to secure the extra-lateral right, but in all claims located since that date parallel end lines were necessary to the enjoyment of the extra-lateral-right privilege.

MANY engineers prefer inverting to erecting telescopes on their surveying instruments, as the former generally afford more light and a clearer, more distinct image of the object. The power of telescopes is determined by the number of diameters it will magnify.

MANY common minerals are the result of alteration, by metamorphism or otherwise, of other minerals. One of the most common minerals resulting from metamorphism is garnet. It occurs in various colors—green, pink, brown, violet, purple and black.

AS FAR as known to 'Concentrates,' there is no book published on pocket-hunting alone. Most of the prospector's field-books, etc., contain a great deal of miscellaneous information which is useful to the prospector, but few or none of them make a specialty of any subject

HOLES may be drilled by hand by means of the jumper or churn-drill to a depth of 20 ft. or more, depending on the weight of the steel. A 1½-in. pipe with drill bits welded onto the ends makes a good churn drill, being sufficiently strong and much lighter than a bar of solid inch steel.

BEFORE constructing a windlass, determine how deep the shaft is to be sunk with the outfit and then build accordingly, aiming to so manage the winding drum that the rope will not wind back upon itself, and also, see to it that the bucket can be raised above the platform without interference. Nothing is so secure on a windlass as some form of safety hook, that must be unlatched each time in order to detach the bucket from the rope.

MANY well-regulated mines where cages are used in the shaft have steel plates on the floor of station in place of the rails, cars from the drifts and crosscuts centering at the station being run upon the plate from the tracks. Near the shaft are flaring guide-rails to direct the car onto the cage.

MONAZITE is probably of more wide-spread occurrence than is generally supposed, but is not recognized by miners. It is a grayish mineral of resinous luster, and high specific gravity, hanging back in the pan like sulphides, gold and other heavy minerals. It occurs in granitic rocks and in areas of schists.

THE cost of transporting ore by wire-rope may, like all other kinds of transportation, depend upon conditions—whether power is required or not, the distance between terminals, etc. The longest aerial tramway in the United States is that of the Penn-Wyoming Copper Co. at Encampment, Wyoming, 16 miles long.

IT is impossible to pre-estimate the amount of water which may be developed in a mine. The first 100 ft. of shaft, or the first 500 ft., do not form a safe index of what may be found at greater depth. The amount of water encountered in a neighboring mine is a better and safer index, though even this is not always reliable.

POTASSIUM CHLORIDE, like sodium chloride, occurs in nature but is much less abundant. It is found at the salt mines of Strassfurt, Germany, overlying a great bed of rock salt, which it resembles. This natural potassium chloride is called carnallite. It is very deliquescent, and readily soluble in water, though insoluble in alcohol.

IN making a test run in a custom mill it is bad practice to clean up after a run of rich rock with rubbers, and immediately after clean-up a run of low-grade ore with steel chisels. The results, particularly of the latter, are likely to prove deceptive. Steel chisels are bad for mill plates at all times, but more certainly so on low-grade ore.

A VERNIER SCALE is a small movable auxiliary scale attached to a fixed scale and which is divided into a number of equal parts, either one more or one less than an equal distance on the fixed scale. The position of one end between two scale marks is indicated by the coincidence of one of its scale marks with the mark of the fixed scale.

WATER boils at sea level at 212° F. With increasing altitude the boiling point becomes lower, until at a sufficiently high altitude the hand can be immersed in boiling water without injury. This fact is sometimes employed in determining altitude, but like the barometer, many corrections have to be made to arrive at the correct result.

THE owner of a mining ditch is responsible for damage resulting from washouts. It is his business to see to it that his ditch and flume are in good condition. An 'act of God,' such as a washout due to a storm, does not render the ditch owner free from responsibility for damages sustained by another from the overflow of his ditch at such a time.

GYPSUM is a non-conductor of heat, which property is frequently made use of in the manufacture of articles which are likely to be exposed to high heat, with a view to prevent damage therefrom. Gypsum is used as a lining in fireproof safes. It is said to be almost impossible to boil water in a kettle, the bottom of which is covered with gypsum.

AN INSTANCE has been recorded of a cyanide vat which had been in use constantly for four years, and which by assay of auger borings from the bottom of the tank returned $13 per ton of wood, an amount scarcely worth consideration when contemplating the difference between assay of ore treated and the results actually obtained by the cyanide process.

PLACER GOLD becomes higher in grade with distance from its source. This is a fact demonstrable in many gold camps. The gold in placers is almost invariably of greater fineness than that in the veins from which it came. In the veins the gold is usually alloyed with silver, but the proportion of silver appears to decrease as distance from the source increases.

A SINGLE one of several co-owners of an unpatented mine on which assessment work remains unformed, can not re-locate the claim in his own name to the exclusion of his partners. He must himself perform or cause to be performed the assessment work, and then 'advertise his delinquent partners out,' as required by law. The statute is very clear on this subject.

ONE fully acquainted with the matte produced by a certain smelter may be able to tell, within a few per cent, what the copper content of the matte is. To do this he should know whether or not the matte contains any lead. A stranger would find difficulty, perhaps, in doing this, but could acquire the ability to do so when he became familiar with that particular matte.

MINERS sometimes mistake clay for talc. White earthy minerals are often difficult of determination. It is often hard to distinguish between talc and serpentine when the latter is schistose, particularly in the field. Serpentine is distinguished from pyrophyllite and talc by its complete decomposition in sulphuric acid, pyrophyllite being only partly decomposed and talc not at all.

THE analysis of a good molding sand will give results within the following limits: Total silica, 75 to 85%; alumina, 7 to 10%; lime, below 2%; alkalies, below 0.5%; oxide of iron, below 6%. The total percentage of iron oxide, lime and alkalies or the total fluxing agencies should not ordinarily exceed 7% in one sample. In a high-grade molding sand used for heavy work they should not exceed 5 to 6 per cent.

A GASH VEIN is one having no great downward continuity. They are probably the result of torsion of the rocks in which they occur, being filled possibly from the walls, or more probably from below by solutions passing along very small fissures—mere cracks. Gash veins occasionally carry high-grade ores, but are not reliable. Several rich veins of this type occurred in the Vanderbilt district of San Bernardino Co., and in the Piñon Mountain district in Riverside Co., California.

PURE calcium chloride may be obtained by dissolving pure calcium carbonate (Iceland spar) in hydrochloric acid, and evaporating the solution. Ordinary chloride of lime (bleaching powder) is made by passing chlorine gas into boxes of stone or lead on the bottoms of which a quantity of moist slaked lime is spread out. The temperature is not permitted to rise above 77° F., by introducing air with the chlorine. The lime absorbs nearly half its weight of chlorine and forms a white powder, which has a peculiar pungent odor, though somewhat different from the chlorine.

THE number of rods of ditch a man can dig in a day depends wholly upon the situation and character of material to be handled. He will, for instance, make better headway on a hillside ditch than he would make in digging a trench of the same cross-section area in a flat, where only earth and loam are to be removed. If trees, brush and roots interfere, even though they be cut away from the surface by the axmen, progress will be slow. The frequent occurrence of large burred rocks also makes considerable difference in what may be accomplished in a day's work.

MILL SCREENS of too great thickness retard the discharge of pulp, those too thin break easily, causing annoyance and loss. The millman should seek a material which will give him the desired firmness, and at the same time lasting qualities and reasonable capacity. It is cheaper to employ a screen giving as large capacity as possible while at the same time doing good work in amalgamating. Too coarse crushing usually leaves too much gold in the tailing, while too fine crushing creates slime which may render subsequent treatment difficult, but on the whole there is an increasing tendency toward finer crushing.

SULPHIDE GOLD ORES cannot be treated by chlorination without roasting for the reason that the chlorine gas does not attack the gold in the sulphide with sufficient rapidity to make the process commercially successful. Some gold-bearing pyrite has been treated raw by cyanidation but for some unknown reason all pyrite is not equally amenable to treatment by this process. When raw sulphide is treated the material must be finely ground—200 mesh at least, and agitation practiced. As high as 97% extraction has been claimed for certain ores treated in this manner. It is customary to roast sulphides prior to cyanide treatment.

IF the Cameron pump was working successfully with compressed air it would give an efficiency of from 12½ to 17% depending upon the condition of the pump and the ratio of the cylinders. If the pump was successfully working with steam under the same conditions, it would probably give 50 % efficiency. Inasmuch as the proportion of the mixture of air and steam is unknown, it would be impossible to give the exact efficiency of this pump, but it will lie somewhere between 12½ and 50 %. If simply enough steam was injected to keep the temperature up to 300° the efficiency would probably be about 25 %, and the efficiency would increase above this point in proportion to the increase of the steam mixture over the air.

FOLLOWING are the charges made by the Government land-offices for mineral surveys, as per paragraph 3 of the General Land Office circular of the United States mining laws: For lode claim, $30; for placer claim, $35; for millsite, $30; for millsite, included in one survey with a lode claim, $20; for each lode claim within and included in the survey of a placer claim, $20; for several lode locations included in one survey, the first location named, $30; all other locations included, each, $25; for several placer locations included in one survey, the first location named, $35; all other locations included, each, $30; for affidavit of $500 expenditure of improvements, after approval of survey, $5. Should an amended order issue, an additional deposit will be required.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

THE BEST SHAPE FOR A SHAFT.

The Editor:

Sir—The discussion on this subject, begun in your issue of February 24, has proved very interesting, but so much has already been published upon the subject that there seems but little more to be said, except in a general way.

The consensus of opinion favors the rectangular shaft of three or more compartments, and with this opinion I heartily agree, that is, where a large tonnage is expected to be hoisted daily, and a large amount of water is to be handled. For such work, I strongly favor the three-compartment shaft with the hoist-ways 4½ by 4½ ft. within timbers and the pump and ladder-way compartment 4½ by 5 ft. As is well known, a great deal of money has been spent and frequently wasted in trying to utilize old shafts, and old machinery, when they are not of the shape and power required for the work to be done. Take the case cited by Mr. R. H. Burrows: Considering the work expected to be done through the shaft, that is, 1,000 tons per day, it would, in my opinion, be far more preferable to abandon a portion of the 10 by 10-ft. shaft and stope up the third compartment, making the excavation for the shaft outside of the timbers 6½ by 19 ft., which would leave a portion of the 10 by 10-ft. shaft, 3½ by 10 ft., that would not be utilized. As the wall-rock is so firm, all that would be necessary to make the timbering strong and secure would be a brace 3½ ft. long from the center brace of one compartment to the wall of the old shaft, or, if the wall-rock should be shattered, this space could be filled with the ground broken in stoping up the third compartment. The excavation of 6½ by 19 ft. would permit the use of 10-in. by 10 in. timbers for wall-plates and center-braces, and while it is claimed that the rock is sufficiently firm to dispense with the use of wall-plates, still, considering the difficulty in placing the center-braces, or dividers, so that everything would be in perfect alignment, it is probable that the extra labor employed in doing this would just about offset the cost of timber. In the sinking of a shaft to a depth of 2,300 ft., unless it is a well proved district, it is impossible to tell what ground would be passed through, or in other words, heavy ground might be encountered at any time, which would compel the use of heavier timbers. For this reason, I would advise the using of filling, or distance-pieces, between the center-braces and the guides. These distance-pieces should be at least two inches thick and the full depth of the center-brace, with the guides lag-screwed through these filling pieces into the center-braces. This answers two purposes: First, it gives four inches leeway to keep the shaft in alignment, and secondly, if heavier ground should be encountered, it will permit the use of heavier center-braces, or dividers, to withstand the pressure of the ground. Of course, in heavier ground, more room can always be made for the wall-plates and end-timbers should it be necessary to use heavier timbers.

This plan would entirely cut out the 'jog' in the shaft, which would certainly be a "thorn in the flesh" to the management, as it would at times cause more or less trouble or delay in the regular hoisting and pumping work; and where such a large tonnage is to be handled, the saving of time that would naturally be lost owing to the jog, would more than pay for the work outlined to cut out the third compartment in the old shaft. This plan would also save a great deal of wear and tear on the tempers of the management and employees.

With such a shaft equipped with skips that will carry five tons of ore, and with large ore pockets, provided with chutes, at the several stations of the mine, the hoisting of 1,000 tons per day would be a comparatively easy matter, for the capacity of such a shaft is practically limited only by the power of the hoisting engines.

For the handling of timbers and men, a 16-ft. steel cage could be hung under the ore-skip. For handling timbers, this cage would take a 16-ft. stick if necessary, which could be readily handled at the stations, and when it came to handling men, a 'false' steel deck could be put into the middle of the cage, making a double-decked cage of it, and with the men that could be placed in and on top of the skip, it would be easy to carry 30 men at a trip, which would consume but little time in the handling of the crew.

In the third compartment would be the ventilating air-pipe, compressed-air pipe, pump-column and electrical wiring, also a ladder-way with platforms at every third set. This compartment would permit of the use of a service cage, run by a separate hoist, for the handling of pipes, pumps and pumpmen, should it be necessary, and as it would not be in use all of the time, the additional cost would be slight.

Fig. 2.

It would also be well to have two large bailing-tanks from 1,200 to 1,500 gal. each, which could be swung into the hoisting-compartment and hung under the skip in case of an accident to the pumps, or if there were a heavy flow of water to be cared for, the mine could be kept dry by combined pumping and bailing.

The cost of such a shaft varies so much in different regions, that but little can be said under this head, as it is entirely governed by local conditions as to price of labor, timber and supplies, but in average hard rock, such as metamorphic greenstone tuffs, the excavation 6½ by 19 ft. could be easily made with an average of 18 holes to the round, six holes for the cut in the center of the shaft, and six holes on each end of the cut. We have broken such ground in an excavation 8 ft. by 20 ft. with the same average number of holes to the round, that is, 18, and where the timbers cost $7.52 per foot of shaft, and the cost was brought down as low as $40 per foot, with the use of machine-drills; but this is less than the average cost of sinking a vertical shaft along the Mother Lode of California.

While economy in every part of the mining business has been reduced almost to a science in this part of California, a fact chargeable largely to the low grade of ore to be handled, it is generally conceded that the first cost of a large shaft and the proper equipment of it should not be considered so much as the benefit and economy in operation that would be obtained from having the best shaft and equipment possible, for where such a large tonnage is to be handled, the saving of a few cents per ton will very soon pay for a great deal of equipment.

JOHN ROSS, JR.

Sutter Creek, California, March 20, 1906.

Fig. 1.

BUILT-UP TIMBERS.

The Editor:

Sir—In 'Concentrates' for the issue of February 17, I note the statement that "Where large square timbers are not available for constructive purposes, timbers may be built up by spiking boards or planks together." It is well added that such a timber is no stronger than a solid timber.

Prof. Edgar Kidwell, in a series of tests recorded in Vol. XXVII, *Trans.* A. I. M. E., showed that built-up beams, when extremely well constructed, had an efficiency of but 60 to 80% that of the solid beam, and these were all keyed or bolted together. I am not a mechanical engineer, but from examples seen in a mill I once had occasion to visit, I doubt if the spiked built-up beam can be depended upon for even 50% efficiency where rigidity is an object, as for example in carrying a line of shafting. Photograph No. 1 shows at the top a built-up 10 by 10-in. timber (A), composed of five planks placed side by side and spiked together, the broken joints between each line of plank coming about three feet apart. This line of timbers was used to carry a small line of shafting, not over 1 15/16 in., I think, transmitting possibly 10 h.p., and as the supports were only 16 ft. apart, with braces to help out three feet on each side of this, it is evident that a solid timber would have given little deflection, if of this size. The result, with this timber, has been a deflection of several inches, and an opening, the shape of an inverted V, has formed at each joint of the 2 by 10, giving a series of points sticking down below the line of the timber. These do not show in the photograph, but a good idea of the amount of the deflection may be had by placing the side of a sheet of paper, or other straight-edge, along the line of the timber in the picture. Undoubtedly the timber should have been built up by placing the plank, one on top of another, in place of side by side, but most substitutes are made wrong at first. What use the longitudinal timber (B) is intended to serve is a question. It is simply bolted to the line of transverse timbers, probably on the principle that "In union there is strength," though it only adds so much more weight. The idea of the truss, presuming the shaft could not have been carried otherwise, was evidently not considered.

Photograph No. 2 shows a post similarly built up which has failed to do the duty expected of it. However, these things serve a purpose in leading to the successes which are "attained through manifold struggles and defeats." No. 1, in the black oil spots on the floor below, and on the timbers, which make the shaft indistinguishable, shows the efforts to keep the bearings cool. It hardly needed the statement of the foreman that the shaft broke often to convince me that this built-up timber had not been a success.

Along the line of failures leading to success may be noticed the housing of the two elevators in No. 2, which was built of green lumber, with the result that after the elevators had been used for a few months for dry, hot material, the slime was all over the mill in the form of dust. The next housing of tongued and grooved material will do better.

GEORGE A. PACKARD.

Boston, March 1, 1906.

THE FIRST WRITER UPON MINES.

The Editor:

Sir—I was interested in the good things in an article appearing in your issue of March 10, 1906, under the above caption; but I shall have to take issue with the idea that Job was "the earliest known writer upon mines." The Creator, in making the home of our first parents, was aware that it would never be a paradise for man without a gold mine. So we are told by the author of Genesis (see Chap. 2: v. 11 and 12) that on one of the forks that watered the Garden of Eden "there is gold. And the gold of that land is good." In other words, it was gold of good quality, over 900 fine. According to the accepted biblical chronology, this mention is 2,500 years before Job. While there are many references in sacred history which go to show that the precious metals, gem stones and shells were valued and used from the earliest dates to which we may trace back,

there is little reference to the mines themselves and to mining operations. We read that "Abram was very rich in cattle, in silver and in gold." We have the best of reasons for believing that gold and silver were used as mediums of exchange, by weight, at the time of Abraham, 1,800 years before Christ.

In profane history, the excavations and interpretations of ancient records in Egypt tell us that "the quartz veins of the granite mountains along the Red Sea were rich in gold." We learn of extensive mining operations in Nubia and that large numbers of miners were employed at Sinai at the accession of Menes to the throne of Egypt, 3,400 B. C. (See 'A History of Egypt,' by Breasted.) A recent article in *Harper's Monthly* (February, 1906), has a picture of a "part of a tablet of a mining record, with names of 100 miners, 2,500 B. C."; and the writer, W. M. Flinders-Petrie, says, in speaking of discovered tablets at Sinai: "Each king who ordered an expedition had his name and the account of his work carved over his mine. Thus are found Sanekht and Leser of the third dynasty and many others down to the eighteenth dynasty, showing that the mines were worked from about 4,500 to 1,500 B. C." This would indicate that "the earliest known writer upon mines" was an Egyptian, antedating Job by 3,000 years.

MATT. W. ALDERSON.

Helena, Montana, March 13, 1906.

THE BEST SHAPE FOR A SHAFT.

The Editor:

Sir—So far as this discussion goes, the old Mexican shaft is an embarrassment, as very frequently indeed old shafts prove themselves to be; without it, or with the whole surface eroded down to the 320-ft. horizon, we could fairly take up the broad question of the best shape for a shaft, and thresh it out until opinions were harmonized, or proved hopelessly divergent. As it is, however, and to make the best of a bad case, the question shorn of all parasitic attachments is, how the Mexican shaft can best be adapted for the permanent works and what shape can best be adopted for the lower portion. This combination, it can be noted in passing, of adaptation and adoption affords an excellent illustration of the sort of problem constantly cropping up in every-day practice—the modification of the ideal to suit the needs of the particular case.

Considering, in the first place, the present shaft, there is no escape, to my mind, from the use of the whole of the old excavation or none of it, and so far as the latter alternative goes we must admit that the $10,000 to $20,000 it represents must not be lightly thrown away. For the assumed needs of the mine three compartments are necessary, and any other shape, involving the lengthening of one end of the 10-ft. square, so as to get the three in line, could not but be dangerous. If this were attempted, an angle of rock would be left between the new third compartment and the unused portion of the old shaft; this would be always an element of weakness, and, no matter how well the old shaft has stood, there would be constant menace of part of this sloughing off on some bedding or joint plane. At best this would throw unequal pressure on the timbers, resulting in trouble with alignment, guides, and pump-column; and at the worst, it would be a constant source of expense and delay for repairs. Nor could it be told to a certainty at the start, by the most painstaking inspection, whether this was likely to be the case, for the shattering during the course of the proposed endwise enlargement would alter the conditions. As to this point, I cannot think there would be any doubt, particularly when it is remembered that this angle of rock would be 320 ft. high and unsupported except by light timbers. In continuing this discussion, I accept Mr. Burrows' statement that no wall-plates are needed, though of course there must be dividing and end-pieces for the support of guides, etc.

It seems needless to discuss here whether two compartments can be constructed in an opening 10 ft. long, capable of raising 1,000 tons daily from a depth of 2,300 ft., for if 10 ft. will not suffice for two compartments, 12 ft. will, and the 10 by 10 shaft can be easily enlarged to a 10 by 12, by methods that bear about the same relation to sinking that stoping does to drifting. Accordingly, we simplify matters by assuming that a 10 by 5-ft. shaft will suffice for the needs of hoisting. I believe then that the square Mexican shaft can be adapted to the needs of the case for its 320 ft. of depth, and best on the lines suggested by Mr. Burrows, giving two hoisting-compartments five feet wide, with the center piece five feet from the ends. As above explained, this can easily and relatively cheaply be increased, should the needs of hoisting demand it. There are two alternatives in the methods of timbering to be used in this square shaft: the first would be 10-ft. end and dividing pieces, connected by posts; and for the second, sprags would be added between the center and the two ends, and gained into all three. These would be placed on the boundary line between the hoisting-compartments and the large pump and ladder-way. If the walls are really as sound as supposed, it is not likely these will be demanded, but the posts will be essential for a first-class job, as they bind the sets—so called by courtesy—together and distribute to a number of timbers any strains, such as might be caused by a cage sticking on the guides or dropping on to the safety catches. Beside this, being all cut to gauge, they insure regular spacing of the cross-pieces and prevent any single timber, that may have become loosened, falling away from its place. I would say here, in passing, that I am far from favoring timbering a deep shaft other than by full-framed sets, because of this very point: if a block rots away or a wedge falls out, the full-framed shaft timber is merely loose; it is still held in place by post and girt, whereas, in the other case, it becomes an unsecured stull and falls or not, just as fortune favors.

Turning to the lower portion of the shaft, we are all familiar with the oblong shape, and probably the vote in its favor by any group of mining men would be overwhelming. Still it is always in order to go over the points and revise one's judgment, if necessary. The 10 by 10-ft. shaft will demand 25% more excavation than the 5 by 16-ft. shaft, a point that goes to the debit of the square shaft at the start, but possibly the lower shaft could be sunk 8 by 10 ft., or of the same area as the oblong shaft. If no sprags were used to separate the pump-compartment from the others, this would give a 3 by 10-ft. compartment for pump and ladder-way. This would certainly be ample, and enables us to compare the two proportions more surely. In a recent paper of the Institution of Mining & Metallurgy there is given a table from Mr. R M. Catlin's work in South Africa. Summarizing from this, we have in percentages of total time: drilling, 38%; winding rock, 41% (this must be taken as the equivalent of 'mucking'); winding men and tools, 15%; and blasting, 6%. These probably safe figures cut no ice so far as yardage goes, so that the whole question comes down to one of speed. In this, I think, the oblong shaft has the decided advantage. It is a common practice to sink in three-compartment shafts with two bars, two drills and two sets of drill-men. This results: in an immediate gain in speed, in placing the center-cut holes to better advantage and in making possible mucking-out one end of the shaft, setting-up one machine and then mucking-out the other end while drilling is in progress. In a 10-ft. shaft, I have not found this method possible; it results in too much crowding for good work. This argument seems to me paramount in favor of the 16 ft. shaft. If drilling and winding can be made to overlap, the 41% occupied in the latter, as per Mr. Catlin's figures, becomes far less formidable.

The joining of the pumping-compartment in the two portions of the shaft should be done by a gradual slide or spiral, the roof of which should be well timbered and blocked, to obviate any incipient motion. But this will be simple cap-and-post work, and far from difficult.

It cannot be claimed that the arrangement of shaft as favored would be ideal, but there is no question of its answering all calls upon it. In any case, in a modern shaft, pipe-columns would be handled through the hoist-way by the main engine, so that there would be no inconvenience entailed by the 'jog' design.

In closing, it will not be amiss to take up in order the points given by Mr. Burrows, as embodying the directors' view:

(1) As already stated, it would probably cost 25% more to sink the square shaft.

(2) The deeper cut could be made in the oblong shaft, and not the square as claimed, and the holes be placed at a more obtuse angle, therefore getting a better lifting effect.

(3) Shattering of the sides must be nearly proportional to the surface exposed; in the shafts these stand in the ratio of 42:40. This 5% increase of surface would be fully offset by the short ends and the ease of support of the sides in the long shaft.

(4) It is bad economy to have waste space, and a pump-compartment 5 by 10 ft. is much too large for ordinary needs.

(5) For hoisting above the capabilities of a three-compartment shaft, the problem becomes too complex for this off-hand discussion. The 10 by 16-ft shaft would be awkward in the extreme from the surface works to the underground stations and chutes; while the alternative of five compartments in line is open to the same objection I earlier raised as against altering the square shaft to three compartments in line. The only escape from this dilemma is on to the horns of a third, abandoning the Mexican shaft altogether. Any settlement of this involves other than mere engineering considerations.

R. GILMAN BROWN.

San Francisco, March 20, 1906.

CONCRETE piles of an unusual form have recently been tested in New York. They are made by spreading a layer of concrete on wire fabric to which longitudinal rods are attached at intervals. The fabric is immediately rolled up in a special machine of simple construction and the pile then laid aside to harden. It thus contains in addition to the fabric any desired number of vertical rods. In a cross section of the pile the fabric lies spirally from the inside to the exterior of the concrete. If so desired any one of the rods may be made a hollow tube, thus allowing for the use of the water jet process for sinking the pile.—*Iron Age.*

Job on Mining.

Written for the MINING AND SCIENTIFIC PRESS by R. W. RAYMOND.

The article entitled 'The First Writer on Mines,' published in the MINING AND SCIENTIFIC PRESS of March 10, is so highly ingenious and interesting as to warrant, perhaps, the suggestion of a somewhat different view, at which I arrived many years ago, as a result of a careful study of the text with the aid of the leading Hebrew scholar of this country—himself a member of the international committee which made the 'revised version' of the Old Testament.

The Book of Job, though dramatic in form, presents almost no action; and its artificial dialogue, in which each speaker takes his turn, is largely used as a thread upon which separate poems are strung. This is a well-known fashion in Oriental literature. The 'Arabian Nights' is one of numerous examples.

In Job these poems are often competitive—that is, Job produces a poem surpassing in sublimity those which have been recited by his interlocutors. The twenty-eighth chapter is such a competitive poem, the subject being 'Wisdom.' There is no good reason for the notion that the passages in this chapter, which refer to mining, are fragments of a longer document. The author is not undertaking to give a complete account of mining. He is simply illustrating the difficulty of discovering wisdom through mere search for it, by reference to the laborious search of the miner for gold and silver. Incidentally, he sketches for this purpose the two principal branches of mining, operated respectively on the surface and underground—his moral being that, while men take so much pains to discover and win valuable metals, 'Wisdom' cannot be found in that way. Additional particulars about mining were not necessary for that purpose; and their absence is evidence of the poet's artistic self-restraint, rather than of the fragmentary nature of the text as we have it. Indeed, the structure of the text almost precludes the hypothesis that it is incomplete.

In my present statement, the theological and philosophical bearings of Job's argument are intentionally ignored, and this poem on Wisdom is considered simply with regard to its direct descriptions or implications concerning the mining of the period when the work was written.

Correctly translated, and paraphrased in modern prose, the chapter reads as follows:

1. *Underground mining* (Described in the first eight verses).—Silver, gold needing to be refined (as distinguished from 'fine gold' or placer gold, which needed no subsequent treatment), iron-ores and brass-ores, are won underground. The miner presses to the very boundary of the darkness, and searches, to that limit, the rocks as dark as death. Down and away from human abodes he sinks his shaft, in which, forgotten by the feet that pass overhead, he swings suspended. Above him, the earth produces food; but underground, ploughed by fire, it has gems for grain, and gold for clods in the soil. His trail is invisible even to the keen-eyed birds of prey; nor has it ever been traveled by prowling beasts—even the bold lion, who goes fearlessly everywhere.

2. *Surface mining* (Described in the following three verses).—Again, the miner attacks the hard rock, overturning even the mountains by the roots, and cutting new channels, to lay bare the river-beds, in which his eye discovers every precious particle. He prevents the streams from leaking, and he brings forth the hidden treasure.

The rest of the poem declares that Wisdom can neither be won, as wealth is won by mining, nor even purchased with the products of human enterprise. The list of such things as cannot buy wisdom comprises: Gold; silver; gold of Ophir (apparently placer-gold of very high grade, possessing a special value); precious onyx and sapphire; gold wrought into cups; cups of crystal, ornamented with gold or coral; pearls; and Ethiopian topaz. Finally, it is declared that the price of wisdom cannot be "weighed with" (or valued with) pure gold; that is, it has no legal-tender standard of value.

The particular gems, especially the ruby, named in the King James version, must be accepted with some hesitation. The revisers suggest, instead of 'ruby,' either 'red coral' or 'pearls' Corals and pearls are quite appropriate to the poet's purpose, since they may be considered as the products of a sort of mining in the sea. Sapphires may also have been found in alluvial deposits then, as they have been found in the Montana placers. And it is not impossible that they might have been discovered in veins underground, as in the Jenks corundum mine of North Carolina. But it is highly improbable that this was then an important source of supply for them.

The foregoing paraphrase is justified in the main by either the text or the margin of the 'revised version.' Where it differs from both, it is based upon good authority. The chief defect of the King James version which it corrects is the absurd rendering of verse 4: "The flood breaketh out from the inhabitant; *even the waters* forgotten of the foot; they are dried up; they are gone away from men." This totally destroys the meaning and continuity of the poet's description, which the revised version measur-

ably restores. But both versions miss the magnificent contrast between the farmer's crops above and the agriculture of the miner below.

From the translation given above it appears:

1. That the author recognized the difference between underground and surface-mining.

2. That gold, silver, iron and 'brass' were obtained in his day by mining, followed by metallurgical treatment—doubtless a simple reduction by fusion with carbon.

3. That the relatively superior fineness of placer-gold was well known, and, consequently, that no 'refining' of gold, as it occurs in nature alloyed with silver, was practiced. The 'refining' of other gold was probably only a crude fusion of minerals containing free gold.

4. That underground mining was done by sinking shafts, in which the miners were suspended by ropes, and by running drifts "to the boundary of the darkness."

5. That the fracture and enrichment of the rocks underground were ascribed to volcanic causes, with the action of which, on the surface, all men were familiar. This, however, is not a scientific perception, deduction or prevision. It is simply a natural superstition.

6. That surface-mining had gone so far as to involve the diversion of streams into artificial channels, for the purpose of 'bar-mining.' Possibly verse 11 may indicate the employment of coffer-dams, to lay bare single auriferous bars, without diverting the whole stream. The whole description indicates the well-known capacity of the ancients for bestowing immense labor upon the execution of crude methods.

7. That coral, pearls, and sundry gems not to be positively identified, were recognized as objects of industry and commerce, and that their market value, as well as that of gold itself, was increased by the artistic work of lapidaries and jewelers.

8. That the commerce in such products was intercontinental, so that Ophir and Ethiopia were already trade-marks, indicating special quality and price.

9. That rock-crystal (not, in my judgment, glass, though this rendering is preferred by the revisers) was used in artistic jewellers' work, being carved and then adorned with coral, gold, etc. This is not evidence of an advanced state of the metallurgical art. Whatever could be done by simple patience and manual skill has been repeatedly done by primitive tribes, ignorant of the principles of the mechanical arts; and many achievements of such barbaric artificers have been simply the lucky outcome of experiments, involving a vast amount of unlucky and, therefore, rejected, results. Numerous instances of ancient art, offered as proof that the early peoples knew in some respects as much, and in other respects more, than we do, break down under this test. The modern art involves a knowledge of conditions and means, and consequent ability, to accomplish with certainty the end desired. In other words, its perfection is measured, in inverse proportion, by the number of 'rejections' which it incurs in practice. Thus estimated, I am convinced that the 'lost arts' of antiquity, concerning which so much has been rhetorically said, are not worth finding.

Further than I have gone in the above deductions, I do not think it safe to go. But another highly important question remains. Whatever may be fairly shown as to the existing state of mining and other arts by the twenty-eighth chapter of the Book of Job, what is the historic period thus illustrated?

Unquestionably, this book depicts a very ancient, patriarchal age. Yet it is almost equally certain that its theme, argument, and literary art, belong to a much later age. Without discussing the problem in detail, I may here observe that the most reasonable solution appears to leading scholars and critics to be that the drama was written at least as late as 750 B. C., though it describes the social conditions of a much earlier period. Its high literary art and structure favor this hypothesis, which is, *per se*, by no means unreasonable. Historians and poets habitually describe scenes and characters of ages long before their own. Nobody dreams that Homer was a contemporary of Achilles or Ulysses, or that the Bible story of Abraham was written in Abraham's time. There is, therefore, no inherent improbability in the notion that the author of Job clothed his relatively modern didactic message in the drapery of a patriarchal age, long past.

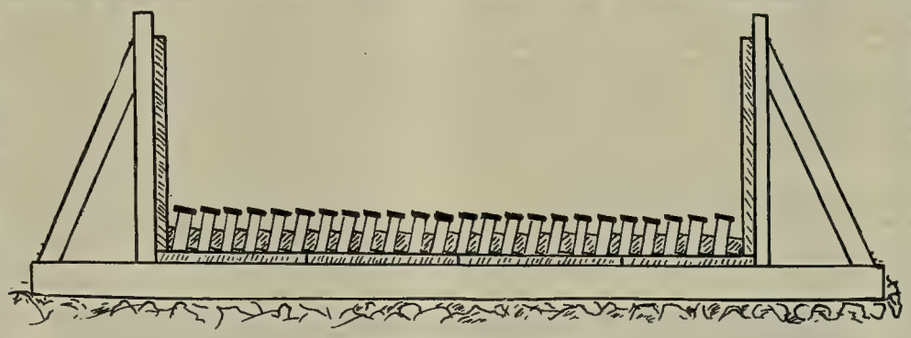
Such a literary artifice, however, cannot possess first-hand archæological authority. We do not adduce 'The Idyls of the King' as direct evidence of the customs of the period of the Round Table. We can only accept such works as second-hand authorities, valuable in proportion to the learning and care exhibited by their authors. The best of them are not wholly free from anachronisms. Even Thackeray's 'Esmond' is said to contain one word not used at the time of which it gives an otherwise perfect picture.

This test, applied to the Book of Job, reveals very few possible anachronisms—and most of these are doubtful. Its chief anachronism is international—namely, it places in the setting of a patriarchal age the discussion of problems which did not trouble the patriarchs; and it includes in this discussion conceptions and suggestions which belong to a much later and more complex state of society. But, aside from this pervading feature, it presents a wonderfully consistent and probable picture, in which, with our present critical apparatus, we can find almost no flaws.

Among these possible errors of the historical imagination, however, we must recognize the picture of mining, metallurgy, arts and commerce, given in the twenty-eighth chapter. In most other respects, the age of Job seems to be conceived as older, even, than the age of Abraham; and, since we now know, through the code of Hammurabi, that in the time of Abraham (say 2,500 B. C.) there was a settled and complex system of industry and law, we cannot positively declare that the poet's age of Job might not fairly present the features under consideration.

Nevertheless (for reasons which cannot be fully stated here), these features must be regarded as inconsistent, to some extent, with the extremely simple, nomadic civilization otherwise set forth, in great fullness of detail, by the Book of Job. At all events, we cannot, with positive certainty, regard this book as authority for any period earlier than, say, 750 B. C. For that period, it simply adds some picturesque details to what we know already about the arts and commerce of the time of Solomon, 250 years earlier. Whether the author of 'Job' was, or was not, correct in putting these descriptions into his poetic reconstruction of a distant antiquity, he cannot be fairly regarded as the "first writer" on mining.

TUNGSTEN.—The output of tungsten ores in Queensland, Australia, which in 1901 and 1902 was only 72 and 55 tons, increased in 1904 to 1,538 tons, while for 1905 the production up to September 30 amounted to 1,029 tons, when the price reached $225 per ton. The price has fluctuated greatly, having been down to a $90 average for 1900 and 1901. It increased still more during the close of last year, going up to $.80 per ton. Such remunerative prices are greatly stimulating the industry and will make some important mining centers. There is great need in Queensland for a cheap and effective machine to save the finer and more flaky portions of molybdenite. In dressing the ore the larger lumps of molybdenite are broken off from the attached quartz by hammer, washed, and put aside for bagging. The finer stuff is screened and that remaining on the screen roughly jigged in water. The heavier lumps collect at the bottom, but the more flaky material, owing to its buoyancy in water, cannot be separated from lighter quartz. A great deal of it is wasted, as there is no sale for anything but clean mineral. The amount of this class of ore, however, does not warrant the use of expensive machinery.—*Consular Report.*



A Riffle for Saving Platinum Sand.

COPPER CONSUMPTION.—According to L. Vogelstein & Co., of New York, the German consumption of foreign copper during January, 1906, as compared with the same period in 1905, was:

	TONS	
	1906.	1905.
Imports	10,333	7,500
Exports	1,099	926
Consumption	9,234	6,574

Out of the above, 7,586 tons were imported from the United States.

THE Barrientos tunnel, 11 miles from the City of Mexico, which is owned and operated jointly by the Mexican National and Mexican Central railroads, it is said, is unique in four respects. It was driven at the fastest rate ever attained in railway tunnel work in Mexico; its cost per unit of excavation was lower than that of any other similar work in the Republic; it is the only double-track tunnel in Mexico, and it was constructed without the loss of a single life. It is 735 ft. long, 37 ft. wide and 28 ft. high, and is lined with concrete blocks.—*Iron Age.*

The Best Riffle for Platinum.

Written for the MINING AND SCIENTIFIC PRESS by DENNIS H. STOVALL.

There appeared recently an article in the MINING AND SCIENTIFIC PRESS, describing the simple panning method of saving platinum sand, as devised by Mr. Wimer, manager of the Deep Gravel mines in Waldo district, southern Oregon, and which is now being used by many placer miners in both California and Oregon. Mr. Wimer is also encouraging his brother surface miners in the work of installing riffles of a design and pattern that will save both the flour gold and the platinum sand. Experience has taught that the best possible riffle for the tailing-flume is steel-strapped scantlings. The next best is blocks, four inches high. For a large flume these scantlings can be 10 or 12 ft. long, and they may be as short as six ft. Those employed at the Deep Gravel mines are 10 ft. long. They are regular 2 by 4-in. scantlings, with ⅝-in. steel straps bolted on the upper edge. The straps are 2½ in. wide, thus projecting over a quarter of an inch on each side. Blocks 1½ in. wide are nailed between the strapped scantlings at each end and in the middle, as spreaders. This leaves a space of three-quarters inch between the straps and of one and one-quarter between the poles beneath. This space beneath the straps and between the poles will of course fill up with small rocks. But that is one of the features of the riffle as a gold-saver. The narrower space between the straps makes it impossible for the rocks to 'boil out,' and they serve the double purpose of holding the platinum sand and disintegrating the clay.

The lower edge of the scantlings to which the steel straps are bolted should be beveled one-quarter inch, so that they lean to one side when fastened down. Every scantling in each section of flume should lean the same way, of course, but to prevent the water from running too heavily to one side, the poles should be reversed in each alternate section. The purpose of leaning the riffle-poles is to switch the platinum sand and light flour gold downward; otherwise they would travel over the smooth steel surface without diving into the riffles below.

Cross-riffles of any kind will not do, because they agitate the water of the flume or sluice; a 'boiling' riffle will cast out fully six-sevenths of the platinum. For the same reason, a reservoir head, self-shooter or any avalanche method of mining, while efficient in washing out and uncovering heavy gold, is destructive to good saving. As a matter of fact, a great flow of water is not needed in a sluice. No more water should be used than is absolutely necessary to move the material over the riffles, to prevent clogging and choking, for the deeper the water the greater its lifting power, and it is the lifting power that prevents the settling of the lighter particles. No riffle should ever be employed that 'lifts' from the bottom of the box. For this reason, the old-time pole riffle—the one made from two to four-inch fir and pine poles laid side by side on the sluice floor—such as is used on many placer mines, is a poor device.

The four-inch block riffles are quite efficient if properly placed, and if care is used in handling them at clean-up time. In order to save the platinum that has lodged between them, the blocks should not all be removed at one time. Only every alternate section should be lifted, leaving the lower section intact. In this way, the sand that is disturbed, in the removal of the entire mass for panning over a tub or vat, is caught and held by the riffles yet in place. As an illustration of this method, suppose the sections of sluice are numbered 1, 2, 3 and 4 from head to tail. The water should all be turned off, with the exception of just a slight flow with which to wash the blocks. Lift the blocks in sections 1 and 2 first, leaving a set in place every 24 ft., provided the sections are of standard size—12 ft. long. When the blocks are out, turn on enough water to wash the clay and top material clean, if enough is not already flowing. Then go into the flume with a shovel and scrape everything loose from the bottom of the flume. It is not a good plan, in shoveling, to scoop up the detritus in big cakes, or to turn it over in huge chunks; simply break it up, stir and loosen it, and when of proper consistency, dip out and pan. This can only be acquired by practice; but as every placer miner is an adept with the pan, it only remains for him to have the necessary patience. But even the best panners can only reduce the residue just so far. There is a certain proportion of the platinum that is too fine to be saved by panning. For this reason it is a good plan to take that portion of the black sand which cannot be saved in any other way and dry it out, after which it can be put in a blow-pan for blowing and thumbing over till the last particle is saved.

Pyrite Smelting Without Coke.—II.

Written for the MINING AND SCIENTIFIC PRESS by LEWIS T. WRIGHT.

It has been shown in a previous article* how successive increments in the proportion of pyrite to the total smelting burden of a blast furnace were attended by a corresponding decrease in the quantity of coke required as accessory fuel in the smelting process and at the same time in the grade of matte produced.

The grade of matte obtained in the smelting of calcined pyritous ores depends chiefly upon the amount of oxidized iron in the charge or, conversely, upon the proportion of iron sulphide, that is, it is determined by the amount of 'solid' oxygen in the charge or by the proportion of 'solid' oxygen to sulphide. It depends also upon the amount of gaseous oxygen left over after the carbon of the coke has been satisfied and, to some extent, upon the grade of ore; but in the case now under discussion the influence last mentioned may be neglected, because on an average it remained constant, and we are not dealing with abnormal results.

It will be interesting to consider for a moment what the oxidation by 'solid' oxygen means in practice. To burn an equivalent of FeS_2 to FeO and $2SO_3$ with the solid oxygen of Fe_2O_3, as in the old smelting and roasting processes, it is necessary to have five equivalents of Fe_2O_3 to one of FeS_2, or 10 of oxidized iron to one of sulphide iron. It was impossible to arrive at this degree of oxidation in a single heap-roasting, or in any economic reverberatory roasting of lump or fine ore in one stage; it could only be achieved in the slow oxidation of the burners at sulphuric acid works which use the purer forms of pyrite. On account of this difficulty in oxidizing so large a proportion of the iron of pyritous ores, the old processes employed so many successive roastings and smeltings.

It is only very lately that the blast furnace has been used as an oxidizing furnace in its fullest sense, and I cannot doubt that if metallurgists will deliberately set themselves the task of pushing the use of the blast furnace to its limits as an oxidizing method, they will attain results very different from those to which they have been accustomed; then pyrite smelting in one stage, before converting to blister copper, will become a general practice.

Results given in my previous article show the relation between the grade of matte and the coke consumption. Grade of matte in such a case represents in a general way both classes of oxidation, namely, by solid oxygen as Fe_2O_3 or gaseous in the air-blast.

The following table shows the relation of coke consumption and grade of matte in the case of cold blast. Monthly averages over a long period were arranged in groups according to the grade of matte produced from the same ore and with the same general working conditions:

COLD BLAST.

Percentage of copper in matte.	Percentage of coke to total burden.	Number of months in average.
22 7	7.6	9
28.5	8 2	12
33.0	8.65	11
37.7	8.7	8
41.9	9.2	17
58 0	10.2	8
65.2	15.1	3

It is important also to consider the relation between the sulphur in the charge and the grade of matte produced and the coke consumption; this can be seen in the following table of results, each being the average of one month's furnace work:

COLD BLAST.

Percentage of sulphur in charge.	Percentage of copper in matte.	Percentage of coke of total burden.
24 5	20 1	6.8
22.8	19.3	7.1
19.5	24.6	8.5
17.0	26.4	7.7
13.6	41.4	10 2
7.7	60.9	16.3
6.8	69.4	15.7

When hot blast was first tried at Keswick it was quickly realized that the coke consumption could be cut down with increase of furnace capacity and, though there were some defects in the design of the hot-blast stove that caused the speedy destruction of the front iron pipes, a better design entirely remedied this trouble.

A six months' comparison of hot and cold blast brought out the following results:

	Percentage of coke to burden.	Percentage of copper in matte.	Tons smelted per sq. ft. per 24 hours.
Hot blast	6.83	49.2	6.91
Cold blast	9.10	40.3	5.87

But to render the comparison complete the consumption of coke with cold blast must be corrected to the same grade of matte made by the hot blast. The coke consumption so corrected is 9.9%. The actual saving with hot blast is therefore 3.07% of coke with 18% increased furnace capacity.

The hot blast brings with it an increased activity; that is one of its merits. There is still another and even more important advantage; with cold blast it was only on rare occasions that unroasted ore could be carried on the charge to make 42% matte, while with hot blast over 50% of the charge could consist of unroasted ore to make the same grade. The attitude of metallurgists in this country toward the use of hot blast in copper smelting is not on the whole cordial, because there have been some failures, perhaps due to the defects in the design of the hot-blast stove, and in other cases the saving of the coke may be unimportant; but the advantages under Keswick conditions were too apparent on its first trial to allow of its aid being rejected.

It will be useful in this discussion to consider for a moment the case of hot blast in iron smelting. Though in the latter case a much greater economy can be shown than in copper smelting, yet the cases are not chemically parallel. When Neilson conceived the idea of hot blast he must have been guided by an instinctive feeling that higher temperature would mean increased furnace activity, but he could not have foreseen all that happened. It is well known that chemical reactions are promoted enormously by increased temperature. Combustion proceeds so much more rapidly as the temperature rises, up to a certain degree of course, which we do not reach in practice, when the counter effects of dissociation are felt. Any practical man would know this. When we come to analyze the results obtained, we find that the most remarkable economy of hot blast in iron smelting was not only that which was the natural result of working at a greater speed due to a higher temperature, but was traceable to another cause that had been unsuspected.

In a case cited by Lowthian Bell† the raising of the blast temperature from 25° C. to 485° C. resulted in the furnace running 2½ times as fast, and this increased activity, which in itself is most important, was accompanied by a reduction of coke from 62.6 to 44.5 cwt. per ton of pig produced.

The cold blast required 111.18 and the hot blast 104.34 Calories‡ per unit weight of pig. This difference of 6.84 Calories is not large and would in itself not have been remarkable had that been the whole story. The faster running due to the higher temperature brought about an economy of only 2.77 Cal., due to the lesser effect of losses by radiation, cooling water, etc., when running fast; and that is about all the heat economy an examination of the analyzed heat balance-sheet will show as the physical result of the increased activity of the furnace due to hot blast. It was discovered, however, that one unit weight of coke instead of producing 2.73 Cal. as it did if burned with cold blast, produced 3.66 Cal. with the hot blast. Here was an enormous economy. The coke was required not only for its physical effect in maintaining a working temperature, but to produce CO to react with the ferric oxide to reduce it to metallic iron, and under the conditions of cold blast the carbon was oxidized in the proportion of 6 12 units of CO to one unit of CO_2. With heated blast, the ratio fell to 3.74 units of carbon as CO to one unit as CO_2. It is this much smaller ratio of CO to CO_2 (since much improved) that accounts for the production of 34% more Cal. per unit weight of the coke used in the case cited above, of hot blast in iron smelting.

In our case the carbon, instead of playing a necessary rôle, is counter-active to pyrite smelting and must be kept out of the furnace as much as possible. It is an expensive middleman, and for the work it does in promoting production of temperature, exacts too high a commission in the shape of the oxygen of the blast.

More recently, Gaylor, working with iron furnaces, has demonstrated, by large scale practice over long periods, that by drying the blast an extraordinary economy is attained, namely, nearly 20% of the coke consumption. One-third of this economy is explained by Prof. J. W. Richards to be due to the more economical ratio of carbon monoxide to carbon dioxide, that is, 1.24 with dry blast in place of 1.91 with moist blast. The immediate effects of a lower ratio between carbon monoxide and the dioxide are an increase in heat production with the same amount of coke, and a decrease in the amount of oxygen and blast required, and the losses that the moisture in this and the heating of the diluting nitrogen entails.

In the future smelting of cupriferous pyrite, carbon will play a subservient part.

I will now review what was finally done at Keswick by keeping coke off a pyrite charge and pre-heating the blast. All the ore, both fine and coarse, was smelted direct in the blast furnace instead of four-fifths undergoing a preliminary outside roasting. For the production of 34% matte the coke was reduced from 8.7 to 0.1% and the furnace capacity was largely increased.

It would have appeared paradoxical in the days before hot blast was applied to iron smelting, to state that hot blast would result in an economy of 30% of the fuel, because it was not then known that the carbon ratio would be so favorable. In our case, we knew beforehand that taking off carbon from the charge would promote the oxidation of the pyrite by gaseous oxygen, and it was quite reasonable to believe that carbon burned outside the furnace to heat the blast would, by reason of the introduction of its heat directly into the smelting zone with the blast, be productive of a more economical and active result than by its introduction at the top of the furnace, where some portion of it is consumed before reaching the actual seat of operations. It is for that reason we found in our work, with partly calcined charges, that one unit weight of carbon burned outside the smelting furnace to heat the blast would replace three parts burned inside the furnace. In the future, by suitable design, the heated gases issuing from the top of the furnace will be made to heat the blast, and then by forcing the oxidation a matte of high enough tenor for converting will be produced in one operation without coke. In order to carry on this operation without coke it is evident that there must be a certain amount of oxidation of the pyrite, and it will be my object now to show in practical terms what is the import of this necessary and minimum oxidation.

From practical results, I find that when the furnaces are running without coke, the charge contains so much sulphur and so much iron as sulphide, and of this sulphur about 77.5 to 90% is eliminated as SO_2. The furnace also must run at a certain speed, say, at the rate of 8 to 11 tons of total burden per square foot of hearth-area per 24 hours.

In the self-smelting of pyrite there are two governing factors, namely, amount of iron and sulphur oxidized per unit weight of charge and the number of unit weights of charge smelted per unit of time. I propose to examine these factors and to give them a simple practical expression.

When pyrite is introduced into a smelting furnace, one-half of the sulphur might be eliminated by the heat alone, and this sulphur might rise to the top of the furnace and there burn to SO_2 with air drawn in below the hood. In practice, only a trifling amount of sulphur escapes combustion there. Thus we could convert the FeS_2 to FeS by the elimination of 50% of its sulphur, and but a trifling amount of useful work would have been done toward the concentrating of the ore into matte. It is only after 50% of the sulphur has been eliminated and the iron, as well as the sulphur, is burning, that the really useful work of concentration commences. Let us assume a sulphur elimination of 90%. That would mean an oxidation of 80% of the iron combined with the sulphur in the form of pyrite. It is found in practice that a charge containing 30 to 33% of its weight as sulphur, which sulphur is practically combined with iron as sulphide, will run without coke under proper conditions of air-supply, etc.

The sulphur elimination will vary, of course, within certain not very wide limits. If, with a charge containing 32% of sulphur as sulphide, 90% be oxidized, then 0 288 of a unit weight of the furnace charge will be eliminated as SO_2, and there should be a corresponding oxidation of 0.224 of iron which goes into the slag as FeO. We can neglect the small amounts of magnetic oxide of iron in the matte and metallic iron in the slag. It is a difficult and complicated matter to get a chemical control of the iron of the charge, part of it being oxidized iron in the converter-slag and flue-dust, and there will also be errors in the sampling of the several components of furnace-charge and products. To obtain an absolutely correct balance sheet of the elements of the charge through all the operations is certainly not a simple task.

In the case of an actual charge containing 31.62% sulphur that was running satisfactorily without coke, it was found that 27 8% was lost to the solid products, and presumably in the furnace gases, as SO_2. The iron was 33.25% of the charge, but 5.86 of this amount was calculated from the analyses to be already oxidized, leaving 27.39 as the sulphide iron principally as FeS_2. The slag, allowing for the 5.86 of iron already oxidized, accounts for an oxidation of 21 8 of the iron per 100 of charge.

In almost every case examined there has been a fair agreement between the sulphur and the iron oxidized, allowing for the residuum of FeS that is left on the combustion of the FeS_2, which combustion, of course, is not entirely completed in the blast furnace.

In the self-smelting of pyrite it is found that from 0.23 to 0.27 sulphur per unit of charge must be eliminated as SO_2 in the furnace gases and that from 0.19 to 0.25 iron must be oxidized in the furnace. In a case of partial pyrite smelting the respective amounts of sulphur in the charge and oxidized were 0.23 and 0.17; this was not sufficient for self-smelting and 4% coke was used as an auxiliary fuel.

In the discussion of such technical processes, especially during their early development, when complete scientific investigations are wanting, we require some general practical expression of requirements and efficiencies; it is something to the practical man to have these; to know, in short, that there is a working requirement of sulphur and iron as sulphide on a charge, and that of this a certain percentage must combine with the oxygen of the blast to furnish the heat for the process. I shall state the necessary sulphur component of the charge as 30 to 33% or that one-third of the charge must consist of sulphur with its corresponding amount of iron, which latter for pyrite is about 28% of the charge.

It is necessary for self-smelting that of this necessary minimum of sulphur, which naturally will vary within narrow limits under different circumstances, about 80 to 90% should be oxidized. For every pound of charge one-quarter pound of sulphur must be burned to SO_2 and one-third of a pound of sulphur as metallic sulphides should be put on the charge.

There are two other features of this smelting pro-

*This journal, February 24, 1906.

†*Journal* of Society of Chemical Industry Vol. IX, p. 691.

‡The Calories used in this and previous article are the big Calories usually spelled with a big C.; that is, 1,000 grams water raised 1° C.

cess that require attention and reflection: One, into which the element of time enters, is the speed of smelting. This determines the total heat production, which must be sufficient after all the losses have taken place, and these will not all vary in proportion with the speed of the furnace running, to discharge the matte and slag from the furnace spout at a temperature, say, about 1,250° C. so as to allow of their being handled in settlers, launders, ladles, etc. The speed or rate of running of a furnace can be expressed by tons of charge smelted per 24 hr. per sq. ft. of hearth-area. In my experience in the self-smelting of pyrite from about 8 to 9 tons, running up to 11 tons on occasions, and not falling below 6.5 tons, are required. A practical expression of necessary furnace speed is therefore about 8 to 9 tons. This is much higher than the usual practice with coke-aided smelting; nine tons per 24 hr. per sq. ft. is close to 12.5 lb. per minute.

In one instance the respective amounts of iron and sulphur oxidized per unit of charge were found to be 0.22 and 0.28; therefore the weight of iron and sulphur respectively being oxidized per square foot of hearth-area per minute were:

12.5 multiplied by 0.22 equals 2 75 lb. iron.
12.5 " 0.28 " 3.50 " sulphur.

The oxygen required for these quantities is:

2.75 multiplied by $\frac{3}{4}$ equals 0.78 lb. oxygen.
3.50 " 1 " 3.50 " "

Total.....4.28 " oxygen.

The furnace results, and I am citing from an actual case, show that 4.28 lb. oxygen were being taken to convert the sulphur to SO_2 and the sulphide iron to FeO per minute per square foot of hearth area.

It is now time to consider how much air is required to furnish this amount of oxygen, and it must be remembered that its efficiency in burning sulphides is not 100%. If pyrite burned according to the equation $2FeS_2$ plus 11O equals Fe_2O_3 plus $4SO_2$, it should give a gas containing 16% SO_2 or, if the iron burned to FeO, a gas containing 17.5% SO_2, making no allowance for the trifling amounts of SO_3 formed. I have repeatedly inevstigated this matter with burners in acid works, with roasting and smelting furnaces and converters, and in the laboratory; and I doubt very much whether any such gas can be obtained.

When the SO_2 reaches 12% of the furnace gases the combustion of the sulphide ceases. As a result of these investigations and from practical experience I believe that 70% is about the outside efficiency of air in roasting or smelting pyrite, and I will adopt this factor of efficiency for the present and calculate the amount of air required for the 2.75 lb. iron and 3.50 lb. sulphur oxidized per min. per sq. ft. of hearth-area. One pound of oxygen is contained in 55 cu. ft. air at 72° F. At an efficiency of 70% there was required

for the above amounts of iron and sulphur: $\frac{4\ 28 \times 55}{0.7}$

equal to 336.3 cu. ft. air. Call this 350 cu. ft. of air per square foot of hearth. A furnace of 44 sq. ft., in pyrite smelting, will, under the conditions of the example cited, require 44×350 or 15,400 cu. ft. air per minute.

It has been shown in this article that for the self-smelting of pyrite, a certain quantity of iron and sulphur must be smelted per unit of time per unit of hearth area, and that because all the iron sulphide* on the charge will not be oxidized a certain excess, over and above the quantity required for the heat production, must be contained in the charge, and it is hoped that enough details and explanation have been given to make it clear why the man who starts out to smelt pyrite without providing a certain amount of air cannot expect to succeed in dispensing with coke or in attaining an economical degree of concentration.

COMPOSITION OF MOLDING SAND.—Molding sand is made up of two distinct and necessary components: First, silica in the free state, and, second, silicate of alumina. The free silica gives grain, refractoriness, porosity and low shrinkage to the sand, while the silicate of alumina furnishes bond. Free silica would be useless without the silicate of alumina, as it would not hold together. Silicate of alumina would be worthless without free silica, as it would not have sufficient porosity and would have too great a shrinkage. A confusion exists in the use of the word 'silica' in respect to sand, which I shall endeavor to avoid by designating the silica existing in the free state—quartz silica. There are several other substances present in all sand. These impurities are not at all desirable and are present from necessity rather than from choice. Quartz silica and clay in correct proportions can constitute a good molding sand without the presence of any other substance.—*Iron Age.*

*This term is used to include both FeS_2 and the residuum of FeS left by the partial oxidation of the former.

Making a Whip-Hoist.

Written for the MINING AND SCIENTIFIC PRESS by MATT. W. ALDERSON.

The prospector hoists the rock broken in sinking his shaft with a windlass. If he does any development work when the shaft is down, windlassing becomes arduous. He now needs a whip-hoist. For distances under 120 ft. this hoist is expeditious and economical. There are several ways of making a whip-hoist, the simplest, in my experience, requiring but four poles of four to six-inch diameter, 16 ft. long, two sheaves, four bolts, and a wire rope. The sheaves are placed between two poles, one sheave near the top, over which the rope will pass, and one near the bottom, under which it passes. These two poles then form one of the uprights of a tripod.

A good size for the sheaves is about one foot. Bolts should be of such size as to go through the holes in the sheaves, not less than three-quarter inch, and two of them will need to be 12 to 14 in. long, the other two about eight inches. The lower sheave should be set so that the rope will be about one foot above the track on which the horse walks. The poles should be set so that the upper sheave will be squarely over the center of the skid-way; in hoisting the bucket will be lifted from the skid-way a few feet below the mouth of the shaft. The drive-way for the horse may be at any one of the four sides of the shaft.

Two buckets are needed to work to advantage, one being filled below while the other is being emptied on top. An iron bucket of such size as may be deemed desirable can be bought at any store dealing in miner's hardware, and such a bucket is better and cheaper than one made at the mine. Occasionally, a prospector is unable to provide himself with this appliance and he must make a bucket for himself. In such case a very good bucket may be made from a 30-gal. vinegar or whiskey barrel, from the top of which about four inches have been cut off. Three hoops, stronger than those usually on the barrel, will be needed to strengthen it. The barrel should have an iron strip from the top down the sides and under the bottom; to this the bail should be attached. There should be a ring in the bottom of the bucket for the operator to hold on to when discharging contents.

Fig. 1.

Fig. 2.

Fig. 3.

The poles for the skid-way of a whip-hoist should stand in a straight line from the top of the shaft to the bottom, and for a bucket of the size described they should be 14 in. apart, center to center. Some miners may think the bucket would ride high on such a skid-way, but it really rides easier when a little high. The skid-way poles should be laid from the top of the shaft down and the ends should be beveled, the lower poles lapping on those above, to prevent any chance of the loaded bucket catching on a joint. See Fig. 1. There should be a safety-clutch on the rope, with which one may easily hook and unhook the buckets. The accompanying illustrations give clear ideas of such a hoist as has been described.

A whip-hoist is a most useful and economical arrangement. The raising of buckets filled with ore or waste is a straight pull on a horse and the loads are brought out of the mine as fast as a horse can walk. Two men and a horse will bring out several tons per day. In hoisting from a shaft 100 ft. deep, 12 buckets per hour is a good average for the first 50 ft away from the bottom of the shaft, and 10 buckets per hour for the second 50 ft., when the buckets are loaded with a shovel.

THE excavation of iron ore by electric and compressed-air shovels instead of steam shovels is to be experimented with on the Mesaba range in Minnesota, and an electric shovel is now being built by the Bucyrus Company. The purpose is to economize in power production by generating power at one large central plant instead of by a boiler and engine on each of the numerous machines. The electric power would be generated at the new Duluth water-power plant. Experiments are also being made with a cableway of about 1,000-ft. span, handling grab buckets, the cableway traveling over the ore bed as the work progresses.—*Engineering News.*

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

The rock from Austin, Nev., marked Y. Z., is diorite.

The metallic mineral from Greenback, Ore., is platinum.

The brown, glassy mineral from Tonopah, Nev., marked L. E. S., is a variety of garnet (grossularite).

The rocks from Searchlight, Nev., are: No. 1, quartz-porphyry; No. 2, syenite; No. 3, also syenite.

Sample No. 1 from Oroville, Cal., marked Selkirk, is volcanic ash; No. 2, marked Orovillo, is olivine diabase.

Sample No. 1 from Princeton, B. C., marked D, is felsite. No. 2 is serpentine, in which occurs a little finely disseminated iron and copper sulphide.

Sample No. 1 from Los Angeles, Cal., marked F. G., is a coarse, semi-schistose granite. The prominent minerals are quartz, orthoclase and biotite mica. No. 2 is a sandy mica schist.

The lead-gray mineral from Seattle, Wash., over the determination of which there has been some question, this department having classified it as stibnite, has been submitted to several expert mineralogists, and careful tests made by them has resulted in confirming the original determination as given in the 'Prospector.' The mineral is stibnite, and contains no molybdenum, lead or other mineral than antimony and sulphur.

Sample No. 1 from Goldfield, Nev., marked M. H. D., is mostly quartz stained brown by limonite (iron oxide). The greenish-yellow mineral is halloysite, a product of the decomposition of feldspar. No. 2 is mostly grossularite (garnet). No. 3 is also garnet, with tremolite.

The rocks from Hailey, Idaho, marked J. J. P., are: No. 1, much decayed—probably greenstone; No. 2, aplite, containing some pyrite, possibly gold-bearing; No. 3 is a dolomitic rock, containing free calcium carbonate and some iron oxide. It has the appearance of having come from a vein.

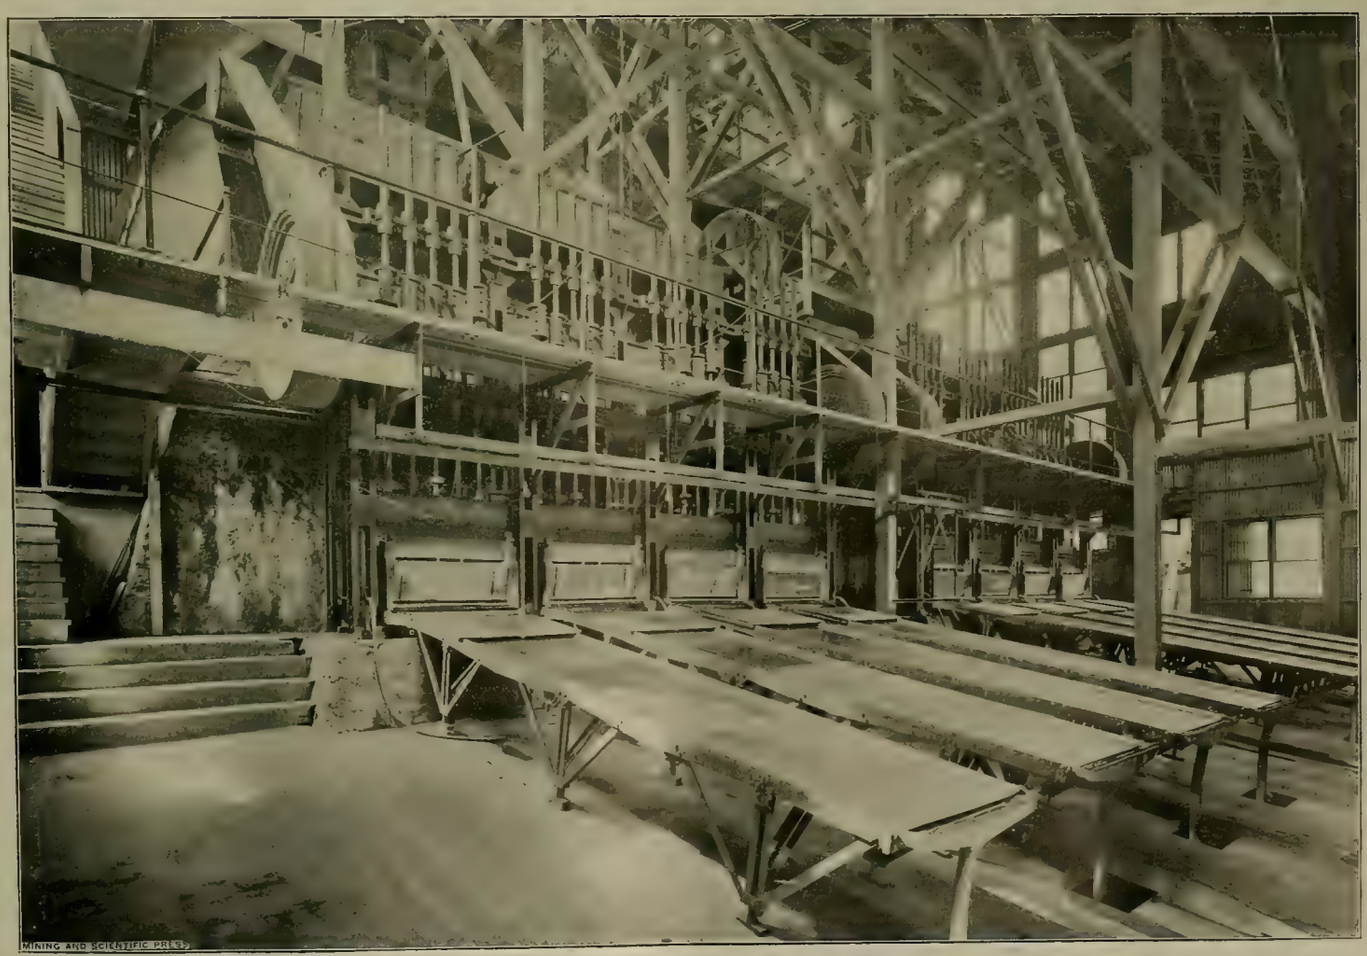
The mineral sample from Bozeman, Mont., is sandstone saturated with asphaltum, and is similar to the California deposits, the material of which is used in street pavements, but is of somewhat lower grade in asphaltum. Prospecting in the neighborhood of this occurrence may be rewarded by the discovery of petroleum.

Samples from Tres Piedras, New Mex., marked R, are: No. 1, rhyolite; No. 2 is a coarse aggregate of quartz grains and feldspar; No. 3 is amphibolite schist carrying iron sulphide; No. 4 is semi-schistose diorite; another, bearing the same number, is quartz schist; No. 5 is an aggregate of both rounded and crystal fragments of quartz, some biotite and earthy cementing mineral; it is a nondescript of some sort, and No. 2 of this lot belongs to the same category; No. 6 is obsidian.

Occasionally senders of rocks and minerals for identification fail to see in 'The Prospector' column the description of their samples. Some of these rocks, etc., are not easy of determination, and it is not always possible to give answers as promptly as expected. The aim is to make these determinations fairly and as accurately as the means at hand and time will permit. No infallibility is claimed in making identifications, but they are, on the whole, correct or approximately so.

The samples from El Paso, Texas, marked W. E. K., may be described as follows: The group of hexagonal hollow crystals is pyromorphite (phosphate of lead), imbedded in cerusite (lead carbonate); No. 2, granite; No. 3, diabase; No. 4, diabase; No. 5, diabase; No. 6 shows numerous rounded grains, and is evidently a fragmental rock, probably made up of volcanic materials, including plagioclase; No. 7 and 8, basaltic rocks; No. 9, a dark colored quartz porphyry; No. 10, quartz porphyry; No. 11, quartz porphyry; No. 12, basalt; No. 13, feldspar porphyry; No. 14, quartz porphyry; No. 15, pink orthoclase and some quartz—essentially granite—but the mica or hornblende occurs very sparingly; No. 16, the same as No. 14; No. 17, granite, same as No. 15; No. 18, similar to No. 14 and 16; No. 19, granite; No. 20, granite; No. 21, granulite; No. 23, sandstone; No. 24, pegmatite.

NORTH STAR MILL, UNDER CONSTRUCTION.



INTERIOR OF MILL, IN OPERATION.

The Central Mill of the North Star Mines Company.

Written for the MINING AND SCIENTIFIC PRESS by A. D. FOOTE.

It is a little over a year since a new 40-stamp gold mill was built near the central shaft of the North Star mine, making 80 stamps now in operation. Although a small mill, it has some peculiarities of design and construction which, after the test of experience has proved their value, may be of interest.

The main foundations are situated about 500 ft. from the shaft on an outcrop of rock at the edge of the waste dump. Extensive excavation on the lower side of this outcrop was necessary to get the required fall of 90 ft. from the top floor to the concentrator-floor of the mill, adding $18,000 to its cost. The foundations and walls, including the ore-bins, are all made of rough cement masonry and the floors are of concrete. The stone was taken from the waste dump adjoining and was so absolutely shapeless that it was deemed advisable to build the outsides or faces with the best of the stone in the usual way with trowel and mortar, then filling in between with all sizes of stone in layers of 6 to 10 in. and then pouring in very wet grout containing five parts of sand to one of cement, the grout being wet enough to keep the work under water as it was filled up. Sand was obtained by washing the tailing of the North Star mill. The cement cost about $5 per barrel, but the sand and stone were so cheap, as also the laying, that the masonry cost rather less than $4 per yard. The battery-foundations were built in the same manner, but the cement ingredient was increased to a proportion of three to one, and near the top it was as two to one. The upper photograph on the preceding page shows the foundations and walls except the upper bins which were built on the slope of the waste-dump after it was filled out to the proper grade, allowance being made for settling. One of the smaller photographs (Fig. 1) shows how the battery-foundations were put in. The anchor-bolts and anchors were placed in position by being hung from a wooden frame and then grouted-in solid all the way up, the top smoothed off with nearly pure cement and, after slight setting, scraped true to a steel straight-edge. (Fig. 2.) When the main walls and the piers for the foundations of the electric motor and rock-breakers were built, the dump was filled out to grade; the lower bins were filled with waste to near the grade-line; the bin-floors were then laid with stone and mortar, and smoothed over. After the walls of the upper bins were built on the dump, as stated, the floors were finished as in the lower bins.

The water supply for the mill is taken from the main water system under about 600-ft. head and is first used on a Pelton wheel, set on a level with the top floor, which drives the rock-breakers; thence it is led to a masonry tank built in the waste dump, back of the mill, from which pipes lead it down through the mill.

The mortars and battery-frames were placed on their foundations with a sheet of pure rubber, one thirty-second of an inch thick, between to act as a paint and keep out water. The anchor bolts are two inches in diameter and the nuts were set up with a hammer, wrench and sledge, working round and round a little at a time until they would move no more. There has been absolutely no movement or vibration of the mortars or bases of the battery-frames as yet.

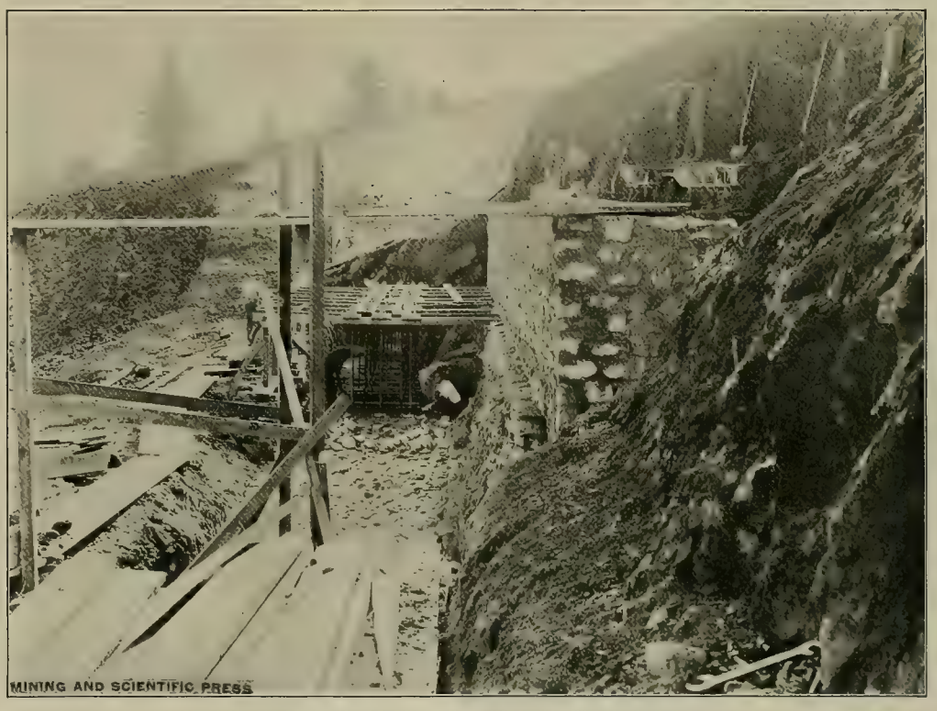


Fig. 1. Construction of Battery-Foundations.

The battery-frames of steel-channels, arranged as shown in the lower photograph, have proved too light and have an intense vibration, of slight amplitude, near the cam-shaft. Two pieces have cracked and been replaced with heavier ones, but the heaviest standard shapes of channels within reasonable dimensions are altogether too light for this work. They should have been I-beams, which are made much heavier for the same dimensions, though they may not be as convenient for connections. The stamps average 1,050 lb each; the drop is eight inches 96 times per minute. There are chock-blocks and inside plates, with a discharge eight inches above the die. The screens are somewhat original, each one is a very thin sheet of steel, 10 by 50 in., punched with 400 round holes to the square inch, one-fortieth inch diameter. A space of solid metal is left around each square inch, which effectually prevents breaking. They last about three times the ordinary screen, or until the holes begin to show enlargement from wear. The sheet of steel is so thin that no appreciable clogging occurs. (See photographic print direct from the screen, as reproduced in Fig 4).

The stem guides are also somewhat original, as shown in the photograph, being very long and carefully turned out to one thirty-second larger than the stems. They have given no trouble and it is thought that this close fitting accounts for the stems wearing so well; only two having broken since the mill started.

It was anticipated that rivets would not stand well in the battery-frames and Columbian lock-nuts were largely used in their stead. It was soon found that the few rivets used were loosening and lock-nuts were substituted everywhere. For a few months more or less tightening of nuts was necessary, but they soon got their seat and remained perfectly tight.

The plate-tables are of cast iron, planed true on top, 18 ft. long and 44 in. wide. The copper plates are 48 in. wide, turned up two inches at the sides, with a curve instead of a corner; the curve allowing expansion in the plate without bulging. The upper edges were bent over flat onto the iron sides of the holders and fastened with brass machine-screws tapped in. The quicksilver traps are built in the concrete floor from which iron pipes, laid in the floor, lead to the concentrators. In the place of the pipes shown in the photograph, at the lower end of the tables leading into the traps, we now use small spitzkasten which serve to size the pulp sufficiently for the concentrators. Across the lower end of the battery-floor is a sunken gutter which carries all washings to concrete settling-tanks on the lower floor.

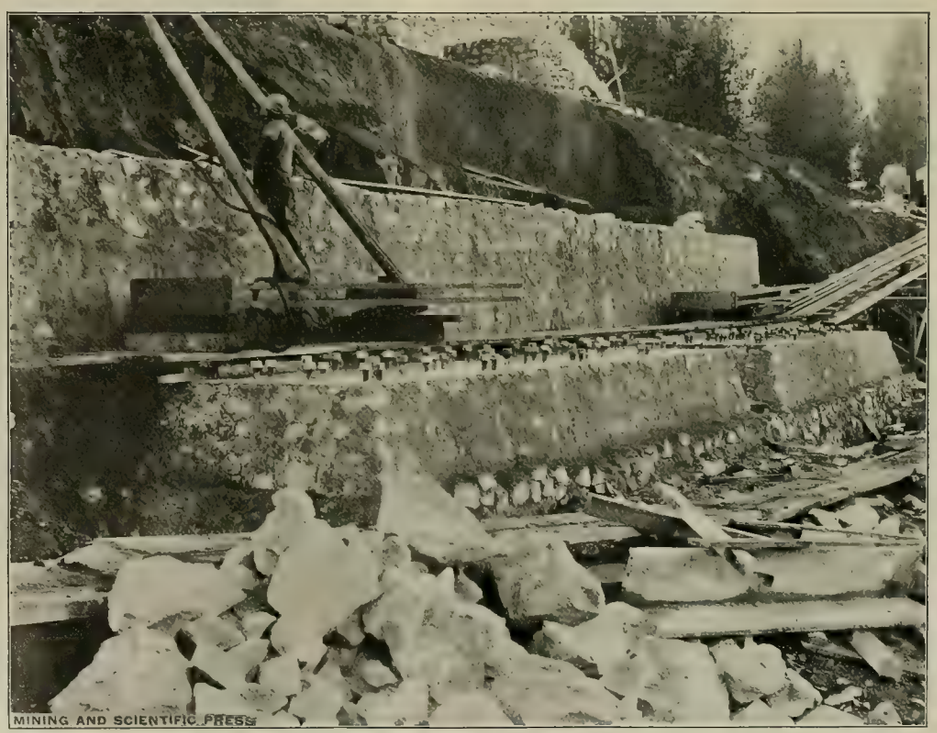

Fig. 2. Battery-Foundations Completed.

The batteries are driven by an induction motor placed on a stone pier that is level with the rock-breaker floor. This arrangement of the power, above and behind the batteries, brings the small pulleys high up, so that they carry the weight of the belts, and it also brings the tight belt on the under side, allowing the use of comparatively loose belts and making a saving of nearly 10% in power.

The clean-up room has the stone foundations carried up five feet high all around. The floor and panning-tanks are of concrete, and the tank-overflow and floor-washings are led in pipes to a concrete settling-tank on the lower floor. An inclined circular ball-grinder for the amalgam and hot and cold water, complete the equipment of the battery-floor.

On the lower, or concentrator-floor, are nine Dodd concentrators, the middling from the first eight going to the ninth. These machines may be described as a circular Wilfley table set on a wagon-wheel, through which is a vertical axle. It will be seen (in Fig. 3) that this arrangement admits of rigid construction, with no appreciable wearing parts. When once set correctly, little attention is needed and their work is fully equal to, or better than, the straight

tables. The ore is run onto the top floor by an electric trolly with fourteen 2½ ton cars which dump onto the grizzlies. It requires nearly two hours each day to furnish the mill with ore from the shaft-bins This trolly also takes out the waste, hauls ore to the old North Star mill and the concentrate from both mills to the cyanide plant.

The mill cost, including the $18,000 expended on excavation, $74,600.

Yukon Mining Laws.

By J. B. Tyrrell.

A mining code should encourage men to find valuable mineral, should provide for the easy acquisition of ground after mineral has been discovered on it, should protect the owners in the employment of any rational mining methods which they care to adopt, and should encourage them to become permanent residents of the country, and to use the riches extracted from the ground as far as possible for the country's development and for the furtherance of the growth of such other industries as it may be able to support.

Miner's License — According to the regulations now in force in the Yukon Territory, every man having any interest in mining property must hold a miner's license, and no location is valid unless the locator is at the time in possession of such a license.

As a quick and easy method of raising a revenue from a throng of enthusiasts rushing to some new strike, this tax has no equal. Seven or eight years ago every man in the Territory hoped to be a mine-owner, and so every man took out a license, and the amount of the revenue thus contributed to the Government was very large. In the year ending June 30, 1899, the amount collected from this source alone was $227,354. Now the number of those who buy licenses is small, being limited to those who actually own mining property, and men who deliberately go prospecting

If this tax is necessary it should be levied on every man, whether in the towns or at the mines, with the exception of the prospector, for mining is the one productive industry of the region and all the people are supported by it either directly or indirectly. If the miner is taxed, the storekeeper also should be taxed, and if the one cannot hold his property without a license, the other should not be able to hold his account against the miner without a license. At present it is a special tax on the vital industry of the country.

In case the tax continues to be levied, the prospector should be excepted. He certainly should be free from impositions of any kind; he should receive the greatest possible encouragement to prospect. People travel about the Territory for many reasons and on many errands, and often find themselves favorably situated for doing a little prospecting; but as a rule such travelers have no license, and so, as they cannot stake claims if they do make discoveries of ore, they will not prospect. It is quite usual to hear the remark from hunters and travelers that they have seen promising surface showings, but that they dared not do any development work because they were not in possession of licenses, for if they should find anything, some one else with a license might come along and stake a discovery over their heads. One may sneer at the possibility of such men finding rich ore, but many of the great mineral discoveries on this continent have been stumbled upon by just such wanderers, and it is the height of folly to say to such men, "We will not allow you to prospect." One rich strike by such men would be worth more to the country than all the license fees that have been collected in the Yukon Territory from the time when gold was first discovered to the present.

Again, a man goes into the wilderness with the deliberate purpose of prospecting for precious metals. Everyone recognizes that his success would mean much to the country; but outfit and provisions are expensive and he has the greatest difficulty in getting together sufficient to last for even a few months in the back country. At such time any expenditure of money, however small, is a serious consideration, and it is discouraging to be told that he may not go out to prospect or attempt to develop the country until he has first paid out for a miner's license part of the money saved or collected for a grub-stake.

In Alaska no license is necessary, and the whole country is free and open to the prospector.

Claims —Since September 30, 1905, any new claims staked are 500 ft. long, presumably in the direction of the pay-streak, and from 1,000 to 2,000 ft. wide. but for several years previous to that time they could be staked only 250 ft. long.

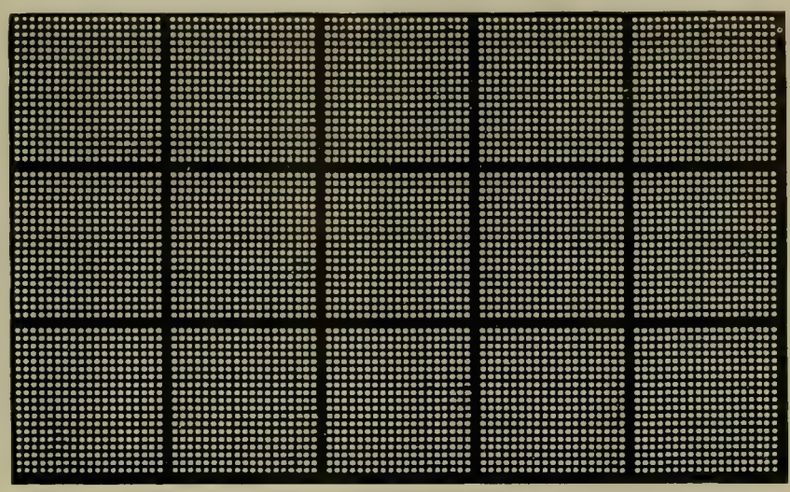

Fig. 4. Piece of Screen. Natural Size.

All claims should be of the same size, and should be as nearly as possible square This is the principle generally adopted in regard to quartz claims, and there is no valid reason why it should not be adopted for placer claims as well, especially such placer claims as are found in the Yukon, where the gold-bearing material is just as completely covered and obscured as in many quartz claims. A square of 1,000 ft. would be a reasonable size for placer claims. In Alaska, which is but a few miles distant across an invisible boundary line, the locators are given 1,320 ft. in the direction of the paystreak and 660 ft. in a transverse direction, and it is unreasonable to expect that prospectors will explore a country where they can obtain claims only 250 or 500 ft. long, when they are but a few miles distant from a similar country where they can obtain claims 1,320 ft. long.

These claims should be located by two stakes, No. 1 stake at one end of the claim and No. 2 stake 1,000 ft. up or down the valley from it. No. 1 stake should govern the middle line of the claim, which would extend 500 ft. on each side of it, and No. 2 stake should be subject to change of position on survey, so that the claim would follow the general direction of the valley. Thus the claim would be located with reasonable accuracy from the first, the locator would obtain the ground he staked, and others would know what ground was open.

According to the present law, the locator is uncertain as to what ground he will finally receive, for the position of his claim is determined by a creek base-line which is almost always run after the claims are located. For instance, the bottom of the valley may be 3,000 ft. wide, and the creek may flow near one side. As water is necessary for washing the gravel, the locator drives his stakes beside the stream and feels confident that he has a claim on the water. A surveyor is sent out from Dawson to run a base-line on the creek, and he runs it down the middle of the valley, though in places, on account of the windings, it will be nearer to one bank than to the other, and the present law declares that the unfortunate locator is to receive 1,000 ft. on each side of that base-line. Thus his original stakes may not be on his own ground at all, but may be far to one side of it, and he may be deprived altogether of the ground which he wanted, which he believed he staked, and which he supposed he owned

Again, as the original claim depends for its position on the base-line to be run subsequent to its location, and not on its own stakes, the amount of ground that is still open to location on one side or the other is altogether uncertain. It is true the ground may be staked at random by stampeders, but no serious development work will be done until the positions of the claims are definitely fixed by the base-line, which may not be for a couple of years after their location. In the meantime, interest in the district may die down, the people may go elsewhere, and the prospecting, which would have been carried out enthusiastically at the time, if the men had known the exact ground on which they had a right to work, is indefinitely postponed.

Representation.—The present law provides that $200 worth of work shall be done on each claim each year, and the regulations of the Gold Commissioner's office fix a scale at which certain classes of work shall be appraised. On concessions, which are larger areas of low-grade ground, it is provided that $5 000 worth of work must be performed each year, such work to be approved by the Minister of the Interior. The intention of these regulations is clear, namely, that a man must work his property more or less continuously, or leave it and allow some one else to work it. In this connection, however, it should be remembered that a gold mining property is only of value on account of the gold which it contains, and that when this has been extracted its value has disappeared, and that care and economy in the extraction of the gold are of far more ultimate value to the community than hasty and wasteful procedure.

The above regulations have now almost entirely lost their original significance, and on claims which the owner deems it expedient to hold over for a time, the representation work has dwindled into a mere tax of $200 on each claim, a tax from which neither the owner nor the country derives any benefit. During the past year there were probably 4,000 claims on which this perfunctory work was done, indicating a waste of valuable capital to the extent of $800,000. When it is considered that concentration of capital is so urgently needed to develop and work the vast gravel deposits of the Territory, this undirected and wasteful scattering of capital and energy is greatly to be regretted.

Title —Claims are held under annual grants from the Department of the Interior, which must be renewed from year to year. This renewal is subject to any change in the laws and mining regulations, and to the acceptance of the annual representation work

Fig. 3. Concentrators in North Star Mill.

by the Gold Commissioner. Concessions are held under leases for twenty years, subject to an annual rental, and also to the acceptance by the Minister of the Interior of annual representation work valued at $5,000.

For the purpose of the small holders, who wish to extract what they can quickly from the ground and then leave the country, the annual leases are in most cases satisfactory; under them the ground is mined hastily and badly, and what gold is left is difficult to recover afterward. Such leases have a tendency to keep the land divided into small lots, and may satisfy the requirements of a roving population; but as a means of furthering systematic mining, encouraging the investment of capital and attracting a permanent population, they are an utter failure. Capitalists are not anxious to invest in remote and speculative mining enterprises unless the title to the property is secure, and there can be no security in an annual lease dependent on the acceptance of certain conditions by an official, and forfeitable for such trivial causes as the failure of an agent to renew a miner's license, or to pay the annual rental on the day appointed. Shareholders of companies will trust a great deal to their directors and managers, but such possibilities of loss will always loom large before them.

The remedy for this is simple. Those who wish to hold their ground cheaply on an annual lease, should be allowed to do so, as long as they remain on their claims for a reasonable part of the working season each year, say, for at least three months. In this way representation and development would go hand in hand, for the two terms should be synonymous, if the former is to have any validity at all. The necessity of residence on a claim would also encourage men to remain within the district.

After a man has placed efficient machinery on his claim, and has opened it up and shown its value, he should be given a title to it that will be perfect for twenty years, at least, without any possibility of forfeiture on account of the acts or omissions of anyone.

In Alaska, a patent to a mining claim can be obtained after a reasonable amount of development work has been done on it, and capital is flowing into that country in abundance, for the carrying on of hydraulic and other mining enterprises on a large scale, while in the Yukon Territory, with its short forfeitable leases, it is almost impossible to induce capitalists to consider investments in properties which would otherwise be most desirable and attractive.*

The Camp Bird Disaster.

The accompanying photographs, which we owe to the courtesy of Mr. B. Kehoe, illustrate a striking scene of devastation. After the snowslide had destroyed the larger part of the 70-stamp mill connected with the Camp Bird mine, a fire broke out and finished the remainder. The cyanide plant, being in a separate building, was not harmed. It was unfortunate that the snowslide should come down just at the place occupied by the most valuable part of the large group of offices and buildings, but it was a wonderfully fortunate coincidence that the mill was shut down at the time of the disaster; the power line had been ruptured by a slide several hours previously, so that there were only seven men in the reading room next the mill; of these, four were injured and one was killed outright. Ordinarily 50 men are employed about the mill.

Camp Bird Mill After the Snowslide.

Both photographs show the smoke arising from the burning mill, but the upper one affords far more than this; it is a fine picture of a mountain landscape. The mill is at 9,400 ft. above sea level and the far peaks are nearly 14,000 ft. in altitude, so that the range of vision is remarkable. Those who have lived in the San Juan will recognize the varying tones on the snow, the dark pines climbing the rocky steep, until breathless they can go no farther, the white tracks of snowslides cleaving the forest in wide lanes, the lone peaks piercing a tempestuous sky and the impression of a vast remoteness — a proud detachment from all human activity, which makes the buildings of mines and mills look like a stray dog in the aisles of a cathedral.

The Mill Burning.

A NEW PROCESS for case-hardening iron has been developed by two Prussian inventors, according to the *Iron and Coal Trades Review*. This process advocates adding to the iron a small percentage of phosphorus combined with a large amount of carbon. The iron is heated in a tempering powder of bone-dust, to which are added 300 gr. of yellow prussiate of potash, 250 gr. of cyanide of potassium and 400 gr. of phosphorus. The receptacle in which the iron and these ingredients are placed is closed and the cracks filled with clay, and then raised to a clear red or white heat. The material treated is then taken out and plunged, while still hot, into a warm bath. It is claimed that a piece of iron can be so hardened that it can not be cut or chipped, but can be welded.

*Abstract from a paper read before the Canadian Mining Institute

RADIO-ACTIVITY. — The hypothesis most generally entertained at present concerning the origin of the enormous power of the emanations of radium is that the power is ultimately derived from the breaking up and death of uranium atoms. Uranium is the most massive element known to chemists, its atom having nearly 240 times the mass of a hydrogen atom. It is supposed that the dynamic equilibrium of these massive atoms is unstable, and that occasionally an atom disrupts or explodes. The event is of extremely rare occurrence, as regards any small group of atoms; but since any appreciable mass of the substance, say a gramme of it, has such an enormous number of atoms, the event of an explosion is of common occurrence. This may be likened to the condition of railroad accidents in the world at large. The event of a fatal railroad accident is rare, and the probability of its occurrence among a given small group of passengers is very small. Nevertheless, taking the aggregate vast numbers of railroad passengers in the course of a year, the total annual number of fatal railroad accidents is relatively large It was observed by experimentalists that a substance which contains radium also contains uranium, and a certain degree of proportionality appeared to exist between them. According to the present provisional hypothesis, uranium will, in the course of millions of years, all be lost by decay into radium, or into substances that in their turn give rise to radium. Radium itself has but a limited lifetime, and breaks up into other substances, of which helium is said to be one. The original stock of energy contained in a massive atom of uranium is thus gradually dissipated in the series of explosions or disruptions ending in relatively inert substances like helium. According to this hypothesis, uranium, and possibly also other substances of massive atoms, are very slowly undergoing disaggregation or disruption with attendant loss of energy; whereas, according to the Laplacian view of the universe, the process of consolidation or aggregation of mass is everywhere in progress, attended by loss of radiant energy.—*Electrical World.*

THE largest electrically driven hoist on the Rand is at the Village Main Reef mine, says the *Electrician.*

The Geology of Jell.

Contributed to the MINING AND SCIENTIFIC PRESS by JAMES F. KEMP.

One of my old friends in college was a very pious individual, named Bill Gosman. His early training had been so strict that he found it difficult in his later years to command a suitable vocabulary with which to relieve his emotions when they became strong, and yet a series of terms which would not offend his conscience. Finally, however, when these occasions arose, he would remark with deep feeling, "Jam the jam thing to Jell."

It is of the geology of Jell which I wish to speak to you and, as I have said, I am the only one who knows about it. For, impelled by that ambition, which every scientific man feels, to spend some time in exploring a new district which no geologist has previously seen, and being anxious withal some time ago to have something striking and novel to describe upon an important occasion like the present, I spent some time in this, the only district near New York which had not previously been exhausted by my colleagues of the geological department.

There have been several travelers in the world's history who have visited Jell. There was Orpheus who went in search of his lost Eurydice; there were Ulysses and Æneas, and in later times Dante. Nevertheless all of these were anything but scientific observers, and while they brought back in each case much that was of great human interest, their references to the geology of Jell are of the most meager character. In fact the references are all physiographic rather than geologic, and relate to plains, rivers, gulches and caverns, without telling us whether the plains were wave cut terraces, lake-basins, or deserts in origin, or whether the rivers were at base-level or not. Moreover, they mix up young, mature and old topographic forms in a way which shows that no one of them had any real grasp of the subject. And as for the geology there is almost nothing said. There remains, therefore, much of deep scientific interest to impart about Jell.

In order to reach Jell you go down to the Tenderloin and then, as has long been known, you are right at the entrance. You hunt around until you find the mouth or crater of the conduit through which the Palisade trap reached the surface. This, contrary to general belief, is on the east side of the Hudson, and from it the hot, molten diabase turned westward, but the old connection was long since destroyed by erosion. At the entrance, much as if you were going into a North River tunnel, you provide yourself with an asbestos suit so made as to be absolutely a non-conductor. When clad in it one can walk without danger amid the most elevated temperatures. The secret of its composition is known to few, but it was familiar to Shadrach, Meshach and Abednego, the three children of Israel who were in the fiery furnace years ago. There are small, transparent windows of muscovite, very much like a stove door, through which one looks without danger. Inside, at the back of the jacket, is an apparatus containing liquid air, for a cooler, and as one expires the exhausted oxygen inside the suit, the latter is fitted with an outlet valve, so constructed as to let only CO_2 pass, since should any free oxygen escape there would be a frightful conflagration under the conditions prevailing in Jell.

Thus provided and having a topographical map ruled in squares, a note book, a compilation book, an infusible platinum hammer, an inside compass, an outside asbestos rock-bag and a sack of condensed food, I set out. I ought also to mention one other ingenious and essential piece of apparatus. My suit was provided with two sets of thermergons or heat generators, one in front and one behind, each outside the asbestos suit. By turning switches, one or both would emit intense heat rays which would be radiated outward, and which, as you will see, were necessary to the trip. I also had an electric lamp.

In the easy descent to Avernus at first you pass over a coarse macadam or pavement of a soft, tufaceous rock, subject to alteration, so that with use it loses all stiffness and resistance. It is called goodresolutionite, and specimens may be even found among uncompleted manuscripts on the surface of the earth. It seems, in its local geologic relations, to be a close parallel with the garnet, vesuvianite and andalusite of the contact zones which are occasionally exposed to view in the upper world, but it extends a long distance, since at present the center of heat is far below the surface.

After a short descent upon the goodresolutionite, I met the level of the ground-water. I noted the change in the character of the wall-rock at this horizon, but did not pause, being keen for the larger problems at greater depth. I waded right into the ground-water, which was of meteoric origin in this case and for which I felt less regard than is cherished by some geologists. Having once gone below its surface a few feet, I turned on the switch of the rear thermergon and at once heat rays were radiated backward, boiling the water furiously to steam of pressures only reached at the point of dissociation of hydrogen and oxygen. The inevitable result was that I was driven forward much as if I had a powerful screw-propeller aft. In a short space of time I passed entirely through the ground-water zone, which, as everyone knows now, is comparatively shallow. John W. Finch has endeavored to show that it is about 1,000 ft. My patent log, which I trailed out astern, registered just 1,017 ft., which shows the extreme accuracy of Mr. Finch's estimate. Having passed the zone of the ground-water, which I may also remark is practically still and moves so little as to be of no particular geologic importance, I walked briskly downward amid dry rocks—just such as we meet in the depths of the Lake Superior copper mines.

Gradually, however, I passed to the limit of the zone of possible fractures, and found the walls of the passage-way closing in and the bottom becoming choked with the spalls and gob which had scaled off under pressure. Moreover, the goodresolutionite began to bulge up in the floor, just as shales and fireclay creep in the entry of a coal mine. For fairly tough and resistant rocks like our local mica-schists and gneisses, Van Hise has calculated that the zone of fracture extends to a depth of 8,342.75 meters. While it is difficult to note in a hasty trip at just what point the possible fractures end, yet by adding to the records of the patent log for the ground-water, the depth of the overlying vadose region and the records of my pacing survey, checked by a pedometer, I found the depth of the zone of fracture to be 7,979.87 meters, or 362.88 meters—say, 1,000 ft.—less than Van Hise's estimate, but on the whole corroborating him very well.

The question may arise in your minds as to how I was able to advance at all as the zone of fracture ceased, but the solution of this difficulty was really quite simple. As the rocky walls closed in, I turned on my front thermergon at moderate capacity, and my rear one at twice this amount. The powerful heat rays melted the rocks for a space of a few feet around, and the extra heat of the rear thermergon generated from the dissolved vapors and occluded gases a preponderating pressure *a tergo* which drove me forward at a good speed and with small difficulty. Gradually I traversed the zone of mixed fracture and flowage, and finally the zone of flowage itself. In the end, and after passing 41,387.63 meters of the latter, I suddenly shot out into an open space and found myself standing upon the pyroclastics which at this point formed the floor of Jell.

You may raise the question as to the possibility of an open space below the zone of flowage, but it strictly follows from physical principles. The zone of fracture ceases because the pressure is so great that cavities are impossible. The rock is squeezed together and compacted as tightly as matter can be. As one penetrates the zone of flowage the matter reaches a point when it cannot be compacted further, and it attains the property of absolute resistance. Below this surface, which is roughly spherical, there lies the region of no strain, and it is a matter consequently of physical indifference whether the central space is hollow or is filled.

So I found myself upon the pyroclastics which at this point form the floor of Jell. I shut off my thermergons, and in the clear, though not bright, unearthly radiance that diffused itself everywhere I sought to examine my surroundings. The cavern was a passage-way of moderate size which led on to more brightly illumined regions beyond. The location was Jell quadrangle, northwest corner. Outcrop, igneous and apparently basaltic in nature. Proceeding 721 meters along the passage to the northeast corner, I found a dike of a leucocratic pyrocrystalline 'jellynose'—striking northeast—and after that uniform granitoid walls of 'gehennose,' which constitutes the main country rock. So far as my wanderings took me in Jell, this was the solid rock and it varies only in that moderate differentiation had produced a greater or less abundance of several constituent minerals. Thus we have dofelic, sodipotassic gehennose, and dofemaniac sodicalcic gehennose. The rock would furnish some interesting microscopic data, but these, though valuable for record, are always deadly dull in a paper that is read.

I pass, therefore, to the real questions of interest which may be solved in Jell. These are the origin and production of the several kinds of the igneous rocks, and the solution of that puzzling problem, the sources of the metallic ores, and more especially the sulphur compounds. My observations show that the various kinds of igneous rocks are produced under the direction of the jevil-in-chief, very much as charges are mixed for a furnace. Thus, that the materials for the various lavas exist at the center of the earth there is no doubt; the only point of interest is the form in which they occur. As a matter of fact, the following are kept in storage reservoirs in a molten state and under pressure. They can be tapped off as needed, and in any desired proportions. There is a reservoir of pure SiO_2, one of Al_2O_3, one of Fe_2O_3, one of FeO, one of MgO, one of CaO, one of K_2O and one of Na_2O. In these there are slight impurities of P_2O_5, Cl, S, etc., but there is also a separate reservoir of FeS_2, mingled with lead, zinc, copper, silver and gold.

When the jevil-in-chief orders andesite, he issues instructions for the proper proportional parts of these ingredients and the subordinate jevils run them together and over into a spout which connects with the volcanic conduit. Into this, and on the principle of the injector, are run under enormous pressure steam and other mineralizers, and the whole mixture, boiling and seething, fuses its way through the zone of flowage and so to the upper world. At rare intervals the metallic bath is tapped into it, especially during the expiring stages, and then ore deposits result as the igneous action in the upper world draws to a close. Time fails me to enlarge upon these topics, although, as you will see, they furnished the clew to much that has troubled many thinkers hitherto.

One other question will arise regarding Jell. Did I see nothing of the various remedial forms of treatment of the wicked which other travelers have noted? I did not, except in one minor case. They generally were given up about one generation ago and passed out of use. The only survival is one for the treatment of wicked cephalopods and brachiopods. Both these groups of organisms are provided with resistant shells into which, after evil deeds on the surface, they retired with impunity. In Jell the wicked ones have been gathered by thousands into a vast pool of water. First acid is turned in on them and it dissolves the shells to their great discomfort while nourishing the tissues; then alkaline calcic solutions are let in which reproduce the shells while destroying the tissues and thus alternately these two reactions are carried out until complete repentance is produced and the head jevil can say, "Now will you be good."

Turning finally even from this interesting sight I retraced my steps to the point where I had entered, passed up through the zones of flowage and fracture, through the ground-water and vadose region and shot up out of the ground in the Tenderloin. No one paid the slightest attention to me, for everyone thought I was just one of the workers in the tunnels under the river who had been blown out by leaky air, an occurrence now so common that it no longer excites remark.*

THREE LEADING AUSTRALIAN GOLDFIELDS.—The figures for 1905 of the three leading goldfields on the east coast of Australia—Bendigo, Charters Towers, and Gympie—are now available, and they show that, as regards surplus of dividends over calls, Bendigo has to take third place. The figures are:

	Dividends.	Calls.	Profits.
Gympie	£195,875	£ 65,727	£130,148
Charters Towers	219,610	93,466	126,144
Bendigo	230,009	175,281	54,728

The figures in each instance show a shrinkage over those for 1904. In that year the surplus of dividends over calls at Bendigo was £199,802, the falling-off being no less a sum than £145,000. At Charters Towers during the same year the totals were: Dividends, £398,128; calls, £83,067; the surplus being £90,000 in excess of that for the past year; while at Gympie there has been a falling-off in the twelve months of £38,000 in the profits. The meteoric Queen's Cross reef has been one of the main causes of the supremacy of the Charters Towers field during the past two years, as in 1904 it paid no less than £200,000 in dividends, but in 1905 the amount dropped to £62,500. The Brilliant and Central dividends fell from £60,000 to £27,500, and Brilliant and St. George from £70,200 to £43,200; but Mills' Day Dawn United and Phœbe came on to the list with dividends aggregating £29,000. At Gympie two mines, the Scottish Gympie and the No. 2 South Great Eastern, were responsible for nearly three-quarters of the gold yield last year, and out of the total of £195,875 dividends earned they contributed £146,000. It is somewhat difficult to give the exact return per ton of ore at the three fields, as the Charters Towers mines are still dealing with accumulated tailing, but the approximate figures are as follows:

	Tons.	Oz.
Bendigo	353,880	215,000
Charters Towers	224 519	171,529
" (cyanide)	208,494	103,407
" (smelters)	.....	45,805
Gympie	213,454	132,403

The total value of the output at Charters Towers was £959,963, or £4 5s. 8d. per ton of ore.—*The Australasian.*

INTELLIGENT PROSPECTING should be based upon scientific principles, for a properly executed geologic map will define the areas within which there is a probability of finding a given kind of mineral deposit. The veriest tyro need hardly be told not to seek coal in a granite, nor would he ordinarily prospect for gold in a region of coal-bearing rocks. The geologist carries this classification of the rocks still further, and may thereby prophesy the occurrence of ore deposits in a region which he has mapped. The actual discovery of the ore is no part of the work of the geologist; this demands detailed examinations and often excavation, such as only individual property owners can make. This point is emphasized because, even among the well-informed, the question is often raised why the geologist does not more often discover mineral deposits. Lack of appreciation of the relation of applied geology to mining is traceable in part to the stories current of the bonanzas discovered by an accident to a mule, the luck of a tenderfoot or the appetite of birds, which are in the popular mind so interpreted as to throw discredit upon geologic science.—A. H. Brooks, in *Popular Science Monthly.*

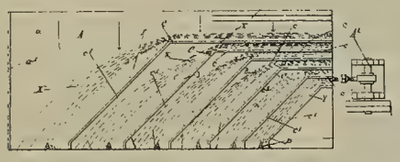
*A paper read at the dinner of the Journal Club of the Geological Department, Columbia University, on the evening of May 18, 1905.

Mining and Metallurgical Patents.

PATENTS ISSUED MARCH 20, 1906.

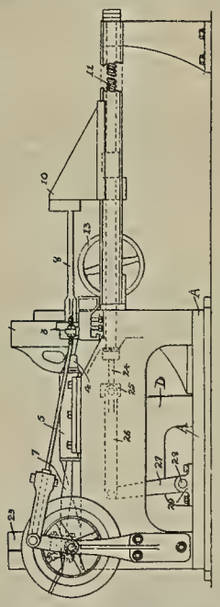
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

ORE-CONCENTRATING APPARATUS. — No. 814,896; J. F. C. Abelspies, Charlestown, England.



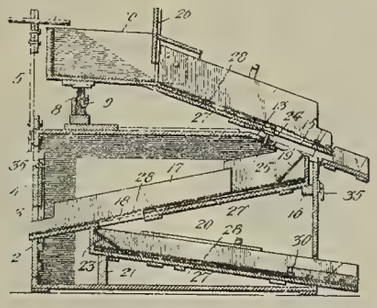
In concentrator, transversely inclined reciprocating table, feeding means extending along portion of upper longitudinal edge of table, longitudinal riffles extending transversely of line of feed for portion of table length, partitions extending from ends of riffles diagonally to lower side of table, and means at lower end of each concentrating-section formed by partitions for separately collecting grades separated by sections.

MECHANISM FOR SHAPING AND SWAGING ROCK DRILLS.—No. 815,845; W. P. Lightbody, Johannesburg, Transvaal.



A machine of character described comprising radially arranged swaging devices, rotatable cam ring for operating same, yielding device for reciprocating ring, an adjustable drill support, and connections between drill support and yielding device, whereby the latter is controlled by the former.

ORE WASHING MACHINE.—No. 815,853; A. S. Mitchell, Oakland, California.

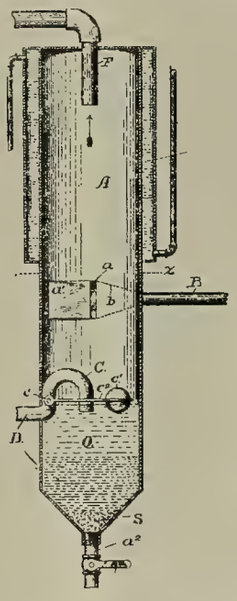


In ore separator, upwardly curved guideway, pivoted receiving trough having wheels arranged for travel on guideway, second trough arranged beneath receiving trough and adapted to receive material from latter, supplemental screen arranged in second trough and onto which material from receiving trough is delivered, and means within troughs for retarding passage of material therethrough.

METHOD OF TREATING MATTE.—No. 814,049; W. M. Johnson, Hartford, Connecticut.

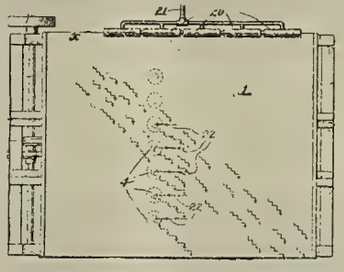
The herein-described method which consists in subjecting copper-nickel matte to the action of sulphuric acid, thereby dissolving nickel and liberating hydrogen sulphide, and leaving a residue consisting in part of copper sulphide; roasting residue to oxide and leaching same with sulphuric acid, thereby forming solution containing copper sulphate; electrolyzing solution to separate portion of copper; and returning spent electrolyte to leaching vats.

SEPARATOR FOR GAS, OIL, WATER AND SAND.—No. 815,407; A. S. Cooper, Berkeley, California.



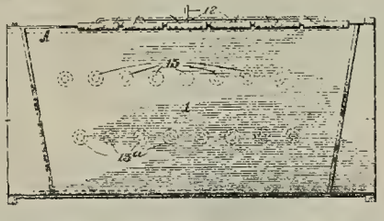
A separator for gas, oil, water and sand, comprising a cylinder, means for delivering material into its side tangentially to its circumference, to impart rotary motion to material, whereby constituents are separated, an exit for gas at the top of cylinder, an exit for sand and water at bottom of cylinder, and an intervening exit for oil automatically controllable by the level of oil.

CONCENTRATOR.—No. 815,679; H. H. Campbell, Steelton, Pennsylvania.



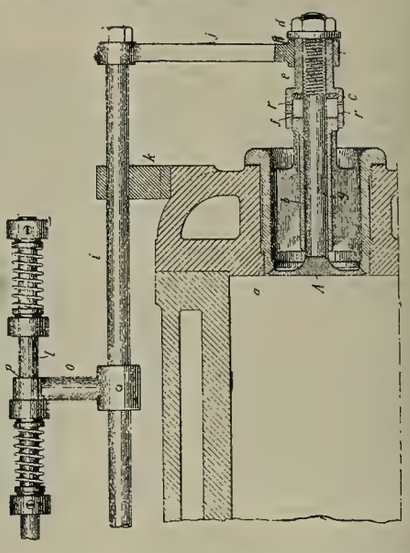
In ore separator, combination of slidable table, means for imparting reciprocatory motion thereto, means for imparting sudden bump or jolt thereto at end of its forward stroke, series of electro-magnets adjacent to table in a line at right angles to the line of reciprocation of the latter, means for effecting reciprocations of magnets reverse to those of table, means for magnetizing magnets at the end of their forward stroke, and demagnetizing the same at the end of their return stroke; together with means tending to advance the ore particles upon table in lines transverse to the direction of reciprocation of table and magnets.

CONCENTRATOR.—No. 815,673; Q. Bent, Lebanon, Pennsylvania.



In magnetic separator, combination of a support for material to be treated, a magnet, means for imparting reciprocatory movement to magnet, means for demagnetizing magnet at or near the end of its stroke in one direction, and means tending to carry off the material deposited on the support in a direction transverse to that of the movement of magnet, whereby the magnetizable particles of material deposited on support are caused to be transported across support partially by being carried by magnet in its forward stroke, and partially by momentum after being released therefrom.

VALVE FOR AIR-COMPRESSORS.—No. 815,488; T. E. Sturtevant, Dover, New Jersey.

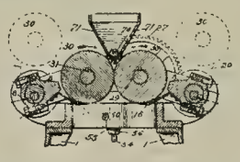


A valve mechanism for air compressors, comprising valve, valve-stem, and valve-stem journal, valve provided with air-cushioning means for retarding opening thereof, comprising cylindrical sleeve on valve-stem and co-operating abutment on valve-stem journal, tappet or operating-rod, connecting-rod, link or arm on connecting-rod having sliding connection with operating-rod, cushioning-springs on operating-rod upon opposite sides of link connection, and a second arm rigidly secured to connecting-rod and having sliding connection with valve-stem, whereby connecting-rod has free movement in one direction without operating the valve.

PROCESS OF TREATING NICKEL ORES.—No. 815,717; C. Langer, Ynspenllwch, Clydach, England.

A process for volatilizing nickel in form of nickel carbonyl, which consists in passing carbon monoxide over material containing finely divided nickel and keeping temperature of said material at between 40° and 50° centigrade.

CRUSHING ROLLS.—No. 815,332; A. C. Calkins, Los Angeles, California.



In ore crushing machines, yokes provided with bearings in ends of frame, crushing-rolls journaled in open ends of yokes, scrapers secured to the bearings, the equalizing bars resting on the roll ends of the yokes, and tension devices attached to frame and removably secured to the bars, whereby an equal elevation of the rolls is maintained during the operation of crushing.

EXTRACTION OF PRECIOUS METALS FROM ZINC ORES.—No. 815,614; A. R. Meyer, Kansas City, Missouri.

The within described process of recovering zinc and precious metals from zinc ores, the same consisting in forming an intimate mixture of comminuted ore and copper, and heating the mass to sublimate the zinc and form a matte or regulus containing the precious metal and the copper, and then separating the matte or regulus containing the precious metal from the residue and condensing the zinc fumes.

Special Correspondence.

LONDON, March 21.

In their report issued for the statutory (or first) general meeting of the Somera Gold Mining Company, Ltd. (Mexico), the directors state that the total number of shares allotted is 216,000 of £1 each, the consideration for the whole being cash. The amount called up so far is 5s. per share, or £54,000.

At the meeting, the chairman, Mr. R. T. Bayliss, gave, in his usually lucid manner, an account of the mining work carried out since the Company was formed. Considerable delay has been experienced owing to repairs having been required in the Somera shaft, which was left in bad condition by the former owners. The developments have also had to wait for the installation of air-pipes and ventilating plant. Preparations are being made at surface to sink a main three-compartment working shaft practically in the middle of the claim. It will have to be sunk to about 600 ft. before reaching the veins, taking probably from 12 to 18 months. The ventilation of the mine will not be perfect until this shaft is completed. The 486-ft. crosscut, after first encountering the East vein of the Esperanza series, was advanced about 125 ft. further, when it struck the West or main vein of that series on which the Esperanza Company have been working their high-grade orebody. A drift has been advanced on this West vein about 40 ft. north and 40 ft. south, showing a strong vein but of low value—only some $4 or $5 per ton. On the East vein a drift has been advanced 70 ft. south and 40 ft. north without meeting with anything of great importance, the values running from $5 to $11 per ton. Developments on the same veins at the 386-ft. level have yielded similar results. The chairman said they were now hoping to meet with at least a portion of the Esperanza west orebody in a crosscut now being run out at the 186-ft. level. So far they had not found a continuation of this orebody at the north end of their claim, but they were hoping still to discover something important in a southerly direction. The length of the Esperanza orebody is 600 ft., and in the Somera claim they had upward of 3,000 ft. still to explore on that vein. Referring to other veins in the property, the chairman said that Mr. Raymond had reported that although there was not much to boast of just yet, the mine was showing a noteworthy improvement.

The prospectus of The Parral (Mexico) Railway & Mining Corporation, Ltd., has made its appearance. The capital is in 300,000 5% cumulative preference shares and 200,000 deferred shares, both £1 each, and the issue includes £400,000 of 5% debenture stock. A sum of £100,000 for working capital is provided. There is what is termed "a strong board," and the reports and valuations of the properties are by J. Fletcher Toomer and J. Edward Capdeville, of Paris, both of whom were instructed by the vendors. There are 17 mining properties of an area of over 300 acres, with a total length on the vein of about 19,550 ft. Of these 15 are proved mines. The properties include mill sites, two mills, pumping and hoisting plants, usual mine buildings, and a tramway connection with all the mines on the Veta Colorada and with the mills and railway, with an equipment of cars for the economical transportation of the ore. The properties are sufficient for numerous companies to work, and after the necessary development work has been done upon the mines, they will be worked on royalties or sold for conversion into public companies. A concession granted to the Parral and Durango Railroad Co. will in due course be carried into effect for the construction of a line to Guanacevi. The capital stock of the P. & D. Railroad Co. is taken over by the new corporation, as also the capital stock of the Hidalgo Mining Company. The present combined railway and mining profits (about £38,000) are sufficient to pay the interest and dividend on the debenture stock and preference shares. The deferred shares go to the vendors as part of the purchase price, the total of which is £800,000.

The directors of the British South Africa Co. (The Chartered Company) have published the figures of revenue from all sources and expenditure as shown in the following table:

	Southern Rhodesia.	North-eastern Rhodesia.	North western Rhodesia.
Year ending March 31, 1905:			
Revenue	£456,385	£28,030	£20,002
Expenditure	590,139	90,512	59,664
Year ending March 31, 1906:			
Revenue, estimated	518,550	25,385	32,740
Expenditure, do.	531,349	60,885	87,421

The directors report that the mining industry continues to show satisfactory progress. For the 12 months to December 31, 1905, the output of gold was 407,048 oz., silver 89,278 oz., lead 570 tons and coal 97,191 tons. The output of gold for 1904 was 267,737 ounces.

The capital of the company to March 31, 1905, amounted to £11,502,415, made up of 5,999.361 shares of £1 each; premiums on shares issued £4,250,174, and mortgage debentures £1,252,880.

The Chartered Company was formed in 1889, having property extending over an area of about 750,000 square miles. It has never paid a dividend, the expenditure always exceeding the revenue. The shares have sold at over £8. The price on the market at present is £1 12s. The assets of the Company in London include a museum of Rhodesian antiquities and curiosities.

At the annual meeting of the Transvaal Chamber of Mines recently held, comparisons were given of the cost of Chinese as against Kaffir labor, with a view to disproving the argument that the Chinese were paid starvation wages in order to undercut the natives. This theory had received support, unintentionally, by the report of the Government Mines Department for the year ended June 30, 1905, wherein it was stated that the wages of Chinese averaged 33s. 6d. per calendar month, while those of Kaffirs were 52s., without making allowance for the fact that, under the ordinance, the coolies worked for the first six months after their arrival at 1s. per day. The following figures for the three months ended January 31 are given to show the real average comparative cost of each kind of labor:

	Chinese on Simmer & Jack.	Natives on Robinson Deep.
Average number employed	4,238	2,030
Average number working	3,767	1,738
Total number of shifts	291,398	145,061
Compound expenses (including time office expenses, but exclusive of any coolies' wages)	9.031d.	9.216d.
Labor supply, procuring, repatriation fund, passport fees, etc	7.297d.	4.217d.
*Wages per man	21.155d.	22.615d.
Total	37.483d.	36.048d.

*Average wage per coolie on the Simmer & Jack for 30 shifts being 52s. 10½d., and the average wage per native on the Robinson Deep for 30 shifts being 56s. 6½d.

The Kaffir share market shows some signs of recovery from the lowest depths, in spite of the threats dealt out by the extreme Radical wing of the Liberal party. According to the organ of that group among the supporters of the Government "more drastic methods" must be enforced "against the gang of impudent aliens who are running the Transvaal." Evidently sharing this view, the Under-Secretary for the Colonies explained the other day in Parliament that so soon as existing arrangements have ceased, instructions will be given to our consuls in China by which an absolute barrier will be set up against the enlistment of Chinamen for work in the Transvaal mines. Unless in the time fixed for the automatic expiration of the ordinance, the new Transvaal Assembly puts forward other proposals, the whole system of Chinese labor must fall to the ground.

A report has been received from Mr. Thos. Kassner on the property of Sanella Outcrop Reefs, Ltd., noticed in this correspondence on January 17. He has made a detailed examination of the reefs, and his conclusions are uniformly favorable. He estimates the yield of gold at 50s. per ton or £125,000 per claim, giving a total for the whole 912 claims of £114,000,000. On this he looks for a total eventual net profit from the block of £38,000,000. From which it would appear that there is still "corn in Egypt," a fact which will not fail to be noticed by the chosen people.

At the annual meeting of Mysore Gold Mining Company, Ltd., last week, the chairman, Captain W. Bell McTaggart, reminded the shareholders that although their nominal capital was only £290,000 there had been spent and paid on capital account close upon £1,000,000. What had they got for that million sterling? he asked—A surface plant perhaps as complete as any in the world. Every kind of engine, electrical power, shafts, buildings of all descriptions, and after paying dividends of nearly £4,500,000, they were left with ore reserves consisting of 613,000 tons worth more than twice the million sterling spent on the mine. On the Irishman's plea that posterity would do nothing for the present shareholders, the Chairman thought they should help themselves by raising fresh working capital instead of providing it out of revenue by a self-denying ordinance of diminished dividends. Although this sentiment was not entirely shared by the meeting, the proposal to create 50,000 shares of 10s. each and to issue them at a premium of £5 10s. was unanimously carried. Arthur Gifford, Mr. Hancock's understudy for some time, has succeeded that gentleman, on his retirement, as superintendent.

The Burma Mines Railway & Smelting Company, Ltd., has been formed with a share capital of £260,000, and an issue of £150,000 of 6% mortgage debenture stock, the proceeds of which will be employed in bringing the ancient silver-lead mines at Baudwen, Upper Burma, and a partially constructed railway, into a profit-earning condition. A novel feature of the flotation is the postponement by the owners of the mine of their entire interest until the debentures are redeemed or converted under option into shares. Messrs. Bewick, Moreing & Co., the general managers, estimate that the net profit to be derived from some 110,000 tons of slag ready for treatment, is £425,700—the operating cost being put at £6 per ton of lead. The average metallic contents of the slags are given as, lead 47.8%, zinc 16.7%, silver about 2½ oz. per ton. The numerous old workings in the mines are not now accessible to any great extent, but the great quantity of material extracted, the high tenor of the assays and the belief that the sulphide ore is practically intact, afford some indication as to what may be expected when modern methods are applied and the mines are properly opened up.

A dividend of sixpence per share has just been declared by Stratton's Independence, Ltd., payable on April 10. Two other dividends at the same rate have been paid since the close of the last financial year, June 30, 1905.

DENVER, April 1.

The Cripple Creek district deep-drainage tunnel project has been under discussion for a long time, and while there is a growing and pressing need for it, there is still disagreement among mine owners, as to ways and means. The problems of the area throughout which drainage will be effective, and the distribution of the cost of the adit, are yet unsolved. Another retarding factor, not so apparent but quite as real, is the time consumed in the strategy of the financiers; when they have the situation that will secure advantages and tend to avoid future entanglements, the work will be started. The latest plan for financing the scheme is that of a local engineer. He proposes that to raise the money required to drive the adit, those who produce the ore contribute an average of 25c. per ton, which, at the regular production of the mines, would yield $12,500 per month; this 25c. per ton is additional to the freight charge, also 25c. per ton, more or less, according to the gold content of the ore. It is doubtful whether this proposition will be taken seriously, considering the large amount of ore—say, 40 to 50%—that is mined under lease. The owners of the ground will be the sole beneficiaries of deep drainage and there are many in the district who think the cost of driving the adit should be paid by them in proportion to the acreage they hold.

On March 27 a large inflow of water flooded El Paso mine, on Beacon hill, from the 1,000-ft. level to the 600-ft. level, filling about three miles of workings in six hours. At the 600-ft. level the water is carried off by an adit. It is generally believed that above the 600-ft. level there are ore reserves sufficient to continue production for three years.

The building on Portland No. 1 shaft, covering shaft-house and machine shop, was burned on March 26. A mine-hoist and 36-in. stroke Ingersoll-Sergeant air-compressor were badly damaged, while the boilers were only slightly injured. The fire caused considerable excitement among the employees of the company; nevertheless, the management coolly and successfully directed the saving of the shaft and the adjoining buildings. The loss is fully covered by insurance.

The almost daily crop of new strikes reported by the press of Cripple Creek impresses the novice to some extent, perhaps, but the ultimate effect on mining is hurtful. The newspaper reports leave the searchers after truth doubting and perplexed, and must have turned aside more capital than has been thus attracted. The resources of the district are far from being exhausted, and good mines are developed with wonderful frequency. Among the recent developments, that of the Ophir mine, on the southern slope of Raven hill, is of more than passing interest. Good ore has been mined from continuous shoots, the ore becoming richer with depth, and to a marked degree at the 700-ft. level. At that level 100 ft. of drifting has been done, opening five feet of smelting ore, running better than the average grade of the district; along with this is a high-grade streak, 12 to 14 in. wide, of sylvanite and roscoelite ore carrying free gold. Pieces of roscoelite, showing but little metallics, sample 61 oz. gold per ton, and a sample of screening from this streak gave 161 oz. gold per ton. The mine has two rich ore-shoots. The Ophir is not stocked; but is owned by Mrs. J. J. Cone, of Cañon City and is managed by Henry P. Dahl.

The Crescent mine, under lease to the Bull Hill Mining & Developing Co., promises to become one of the big mines of the district. The ore was first found at 600 ft. in depth, by a crosscut from the shaft. It is a rectangular body of phonolite and andesite, 130 ft. by 80 ft., surrounded by basalt, which marks the limits of the ore. A stope is being carried toward the surface. About 80% of the entire mass is smelting ore, carrying nearly 1½ oz. gold per ton. Pending preparation to handle a large tonnage of ore, 398 thirty-ton cars have been shipped and about 30,000 tons more broken and left in the stope. Car-loads of screening, netting $4,600 each, have been shipped from this shoot.

CALUMET, MICH., March 31.

Conditions at the smelting plants in the Lake Superior copper district strongly substantiate reports from other sources regarding the urgent demand for refined copper from consumers. While the present indications are for an early opening of navigation at copper country ports, the smelters are rushing their product forward to the Eastern seaboard without delay. The Michigan smelter of the Stanton-Paine mines and the Calumet & Hecla smelter have broken all records in the matter of refined copper production lately. The Michigan smelter turned out approximately 7,500,000 lb. of fine copper last month and arrangements are being made for enlarged capacity. The Calumet & Hecla is operating extra furnaces at its smelter and shipping copper as rapidly as it can be turned out. Navigation at local ports is expected to open within two or three weeks, but the first lake steamers will find the wharves practically bare of the metal in marketable forms.

At the Winona mine, 11 drills are in commission. Of this number, four are in use sinking, two in each shaft, and the remainder are in use driving eight drifts. The drifts north and south from No. 3 shaft at the eighth level are in commission on alternate days. Drifting south at the sixth and seventh levels of No. 3 shaft, and north at the seventh of the same opening is under way. Drifting in No. 2 shaft is in progress at the seventh, eighth and ninth levels south.

There are some points in favor of the Winona resuming production, most important of which is the present price of the metal. It would be necessary however to install rock crushers in No. 3 shaft and provide rock bins there before shipments could be made. A railroad spur to that shaft would also be required. It is believed that the Winona's present reserves are of sufficient size to permit daily shipments of 200 to 300 tons of rock. There are facilities available for the operation of five more power drills, but it is probable that the compressor capacity would be increased if production were decided upon. This addition could be made at comparatively little cost.

Captain Samuel Robins and John Freeman are no longer connected with the Tamarack. Captain Robins left for the West, where he will be associated with a brother in mining work.

Some rich ground is being opened in the lower levels of No.1 and No. 2 shafts at the Mohawk, the average quality of the lode at these points being superior to that above the ninth level. Drifting south from the new No. 5 shaft also reveals productive ground. The Mohawk is shipping nearly 2,000 tons of rock daily now, No. 1 and 2 shafts being the main source of supply. The era of heavy construction expenses at the mine is over, but there will be small expenditures from time to time for improvements. Work at the stamp-mill is going forward. The steeple-compound head is treating 650 tons of rock daily. The other stamps will be changed to this type.

Another shaft will probably be started at the Champion mine next year. It will be situated south of E shaft. Drifts from the latter are penetrating the ground which will be opened from the new shaft and draining it of water. The drifts south from E shaft penetrated the strike-line of the new shaft some time ago and are being driven forward without interruption. Work there will be continued and the ground is part of the most valuable territory developed in the Champion mine.

No. 4 shaft of the Wolverine is making a creditable output and the increased rock shipments from that source largely offset the loss from No. 3, where the rock-

house was destroyed by fire a short time ago. Three shifts, working eight hours each, are employed at No. 4. It will be a matter of only a few weeks before No. 3 is ready to go into commission again.

The Lafayette Mining Co. has paid a dividend of $2.42 per share to its stockholders from the money received from the sale of the property in Ontonagon county, to the Copper Crown Mining Co. Another dividend will be paid, liquidating the affairs of the company. Essex Copper Co. has paid its stockholders $1 per share, the funds having been secured from the sale of its Ontonagon county mineral lands to the Copper Crown Co. Another dividend may be expected in the liquidation of the corporation. Neither of these concerns have done any work for several years, but the Copper Crown Co. proposes to develop the properties as rapidly as possible.

SALT LAKE CITY, April 3.

What will probably prove to be the most important mining litigation since the famous Mammoth-Grand Central case, is the suit filed in the Federal court at Salt Lake on March 31, in which the St. Louis-Magnolia Mining Co. is plaintiff and the Silver King Mining Co., David Keith and Thomas Kearns, president and manager, respectively, are defendants. Trespass and unlawful extraction of ore is alleged. Judgment is asked for to the amount of $900,000, or three times the actual value of ore claimed to have been taken from one level. The filing of this case has been expected for some time, and is the result of the refusal of the Silver King management to settle the claim out of court. The property of the plaintiff is situated almost in the center of the territory owned by the Silver King, and, it is said, the defendants gained access to the disputed territory by running drifts into it from the Silver King working shaft, and that some of the richest ore ever hoisted out of it was obtained from that portion of the vein involved in the dispute. The defendants admit having extracted ore from the ground claimed by plaintiff, but say they were entitled to it because of apex rights. The St. Louis-Magnolia Co. is sinking a shaft, which is now down about 145 ft., and has already encountered considerable ore. The properties concerned are at Park City.

At a depth of 25 ft. below the 700 level of the Cyclone mine at Stockton, a vein of solid shipping galena has been cut.

President Samuel Newhouse, of the Boston Consolidated Mining Co., has announced that as soon as certain deeds to the ground included in the site for the proposed 5,000-ton concentrating mill, near Garfield, Salt Lake county, are passed, ground will be broken and the work of laying the foundations commenced. It is expected that contracts for the structural material for the several buildings will be awarded within the next 30 days, as well as that for some of the equipment. While experiments are still being made at the $25,000 plant put up at Bingham for that purpose, it is practically a certainty that the ore brought to the mill will be crushed by stamps.

Development work has been progressing satisfactorily at the property of the Bingham Group Mining Co. at Bingham. A vein of lead carbonate ore, 25 ft. wide, has been opened, several feet of which is high grade. Albert Booth, of Bingham Junction, is manager.

The ore shipments from Park City last week amounted to 4,360,000 pounds, the contributors and amounts being: Silver King, 1,714,800; Daly-Judge, 1,057,000; ditto (zinc middling) 38,000; Jupiter, 16,000; Little Bell, 105,000; Daly-West, 1,150,000.

During the past week three new slime-tables were added to the equipment of the Daly-Judge mill at Park City: the three zinc-tables, installed recently, working in conjunction with the slimers, all but from one to two per cent of the zinc being saved.

The special meeting of shareholders of the Mammoth Mining Co., called to consider the matter of re-incorporating under Nevada laws with a capitalization of 400,000 shares of the par value of $2.50 each, has been indefinitely postponed. The company is incorporated under Utah laws at the present time.

The worst snowstorm of the winter occurred on the 1st and 2nd inst. The roads are in such deplorable condition that the movement of ore, where teaming is necessary, is accomplished under great difficulty.

The management of the New England mine at Bingham is receiving lumber for a new boarding-house. A contract will be let shortly for a new compressor. Henry M. Adkinson, of Bingham, is manager.

A special meeting of the stockholders of the South Columbus Mining Co., operating at Alta, has been called to amend the articles of incorporation, which will allow directors to levy assessments to the maximum amount prescribed by law. At present the levy is restricted to one cent per share every 60 days.

Shipments are being made from the Eagle & Blue Bell mine, of Tintic district, to the amount of 80 tons daily. This property is controlled by the Bingham Consolidated Mining & Smelting Co. The Bingham properties of this corporation, owing to the expiration of the contracts under which the ores of the Utah Copper and Cactus mines have been smelted, are being called on for an increased tonnage amounting to about 200 tons per day.

The management of the Utah Copper Co. has announced that it is the intention to commence the construction of the second section of the concentrating mill at an early date and that its completion will follow closely that of the first section. Contracts for all of the equipment for the first section will be let within the present month and the successful bidders will probably be requested to double the order. The officers' messhouse and dormitory, as well as the warehouse and machine shop, are practically completed.

Last week's shipments from the mines of Tintic amounted to 191 carloads, the shippers and amounts being: Centennial Eureka, 50; Ridge & Valley, 4; Eureka Hill, 20; Bullion Beck, 11; Uncle Sam, 5; Gemini, 19; Beck Tunnel, 8; Victor, 1; So. Swansea, 1: Victoria, 4; Eagle & Blue Bell, 12; Mammoth, 19; Lo. Mammoth, 2; Swansea, 4; Grand Central, 15; May Day, 5; Ajax, 5; Yankee, 2; Dragon Iron, 2; Brooklyn Con., 2.

The total ore and bullion settlements during the month of March, as reported through Salt Lake banks, aggregated the total of $2,080,550.

The Coffey group of claims, located near Shem City, in Washington county, have been bonded to Samuel Newhouse.

TORONTO, March 31.

Interest in the Cobalt mining camp increases as the season advances. The promised rush of prospectors and speculators has fairly set in, and, though the weather, up to latest accounts, has been such as to render effective prospecting difficult or impossible, the excitement is well maintained by reports of big strikes in the mines under operation, by company promotion and by speculation in real estate. Not a week passes without the launching of several new companies, most of which, in the opinion of practical men, are absurdly over-capitalized, considering the nature of mining operations in the Cobalt area; nevertheless, the shares of the most promising, or best advertised, propositions are rapidly being taken up. The promoter's opportunity has come with the practical exhaustion of the field for prospectors in the Cobalt area proper, the township of Coleman being virtually all taken up, though it is regarded as probable that many of the claims will eventually be disallowed as not being based on the discovery of valuable mineral, such as the law requires. Even should this be the case, the rush is so great that prospectors will need to go much farther afield. Attention is now being directed to the adjacent township of Bucke, where some promising prospects have been developed.

As intimated in a previous letter, however, the burning question among all interested in the future of the camp is the disposition which will be made by the Government of the Gillies timber limit—a large tract of mineral land lying directly south of Cobalt. This tract, which is heavily timbered with pine, is under license for lumbering purposes and consequently barred to prospectors. The timber license gives the lumbermen no claim to the soil or the minerals, but gives them the right to exclude prospectors or others. It is known to be extremely rich in silver, and by an agreement made with the licensees they have undertaken to remove the timber by October 1. Lately uneasiness has been excited by the widely circulated report that capitalists of Bay City, Mich., having obtained maps of the district, had secured the services of engineers, located claims covering the most promising veins and prepared papers to be filed as soon as the district is thrown open. Frank Cochrane, Minister of Lands and Mines, has reassured the public by stating that even had such proceedings been taken, it would not benefit the parties in the slightest or entitle them to any consideration in preference to others. He further set at rest the general expectation that the Gillies limit would be thrown open in the spring by stating that this could not possibly be done before October 1—the date set for the clearance of the timber—and that when the time for opening the tract for mining arrived everyone would be put upon an equal footing. As the position of the deposits is known to many prospectors, the ordinary method of locating claims could not be followed without serious consequences and a scramble that would result in endless confusion and disorder. It is therefore regarded as altogether probable that mining rights will be disposed of to the highest bidder, or that some other entirely exceptional plan will be adopted.

Prospecting in the Cobalt region has generally been confined to the Lower Huronian formation, in which nearly all of the more important finds have been made, and such indications as were found in the diabase have been regarded as of small account. As the monograph by Prof. W. G. Miller, provincial geologist on the cobalt-nickel arsenides and silver deposits of Temiskaming (published as Part II of the Bureau of Mines Report, 1905) pointed out, there are exceptions to the rule, several localities being mentioned, in which veins occur in the diabase. Recent experience has shown that some of these offer opportunities for profitable development. A diabase prospect, staked on a small calcite vein, a little west of a point on the railway between Cobalt and Haileyburg at a depth of 40 ft. shows a widening of the vein, which also assays well and gives indications of becoming a profitable mine. Tunneling operations at Diabase Mount, east of Peterson lake, shows that this formation overlies Lower Huronian, the plane of contact being practically horizontal. As the field for prospecting in the Lower Huronian is narrowed, the possibilities of the diabase will receive more attention.

A mining exchange has been established; the temporary quarters will be formally opened early in April. It is known as the Cobalt Open Call Mining Exchange, and is conducted on the Australian system, being open to the general public for buying and selling transactions in the evening, with private call meetings in the morning. The first 25 seats were speedily taken up at $50 each, the price being afterward raised to $100. Another evidence of the rapid development of Cobalt as a mining center is that the labor troubles, inseparable from modern industry, are beginning. A miners' union has been organized with the result that the secretary-treasurer, a miner from Montana, in the employ of the Nipissing Mining Co., was promptly discharged by the manager, who warned the men that the company would not retain in their employ anyone known to be a union man. It is said that an agreement to this effect has been arrived at among the mine-owners, who have also arranged a scale of wages, as follows: Miners, machine and hammer men, $2.25 per day; laborers below ground, $1.75; laborers above ground, $1.50, with board in each case.

Compressor plants are being installed at the Drummond and Jacobs mines in the Kerr Lake district. The machinery has to be hauled in from Argentite station on the Temiskaming and Northern Ontario Railway, half way between Cobalt and Haileyburg.

The position of Director of the Canadian Geological Survey, which has been vacant for some time since the death of the late Dr. Dawson, has at length been filled by the appointment of Albert P. Low. Mr. Low is a native of Montreal, and after graduating from McGill University in 1882 was appointed in the same year to the Geological Survey staff. His work for the past 25 years has been mainly in Eastern Canada, and he has made extensive explorations in Labrador and the country south and west of Hudson Bay. He commanded the exploring expedition of the *Neptune* to the north of Hudson Bay in 1904-05, and is regarded as one of the foremost Canadian geologists. Dr. Robert Bell has been acting director of the survey for some years, and in recognition of his services in survey and exploration work has been awarded the gold medai of the Royal Geographical Society of England.

Though owing to the Cobalt excitement, developments in the eastern mineral district of Ontario have not attracted much general attention. Steady progress has lately been made in the mining industries of Hastings county. A smelter is to be installed in the Eldorado Copper mine, now operated by the Medina Gold Co. The copper vein here was discovered beneath deposits of hematite ore. A shaft has been sunk to the depth of 160 ft. and the vein is found to have a well-defined width of 16 ft. Two carloads of the ore have assayed over 10% copper. The establishment of the smelter will make it possible to work a number of small copper deposits in the neighborhood, which have been lying idle.

BUTTE, April 1.

The East Butte Mining Co. now has ten sets of lessees at work in various properties, from the royalties of which the company has, during the last two months, derived a good net income, after paying for all development work, extensive improvements, salaries and office expenses. The lessees in No. 2 a few days ago cut, at a depth of 140 ft., a body of solid copper glance two feet wide; this is the same vein cut some time ago in the Symons mine of the company 300 ft. northwest of No. 2 at a depth of 200 ft. In the Symons, the rich streak is four feet wide. The company has completed its three-compartment shaft on No. 1 to a depth of 350 ft. The shaft was originally of two compartments, and was enlarged from the bottom to the top, the surface just having been reached. In the coming week sinking will begin from the 350-ft. level and a depth of 1000 ft. will be reached late in the fall. When a depth of 500 ft. is attained, a crosscut will be run to the company's lines north and south, and all the veins, about 21 in number, will be opened. The company will then begin stoping and mining from that depth to the present upper workings, giving from 200 to 250 ft. of stoping ground, which will make it possible to hoist and ship about 500 tons of ore daily. An encouraging indication is that the veins are widening with depth, and the copper glance has thus far been found in larger quantities. The new engine and compressor for the new shaft are expected to arrive daily. The company will build the new hoist over the old one, and will continue sinking with the old machinery while the new is being put in place. The plan is to sink another shaft at the extreme southern end of the company's ground and connect it by underground workings with the shaft on No. 1. The lessees are hoisting about 200 tons of ore per day, half of which is first-class and is shipped direct to the Washoe smelter, and the other is concentrating ore and goes to the concentrator of the East Butte Co.

By striking a rich body of ore in the Snoozer mine at a depth of 1,500 ft., the Raven Mining Co. enters the list of copper-producing companies. The company for several months has been developing the vein on the 1,200-ft. level and has taken out a lot of ore during the progress of development. While the work was going on on the 1,200 a crosscut was run from the 1,500 station which cut through one vein 30 ft. wide, and during the past week it cut another vein, known as the north vein of the Snoozer. The orebody at that point is 12 ft. wide and carries ore that averages the entire width 7% copper, 15 oz. silver and $1.50 gold per ton. Some of the ore runs 30% copper and 50 oz. silver. It is the same vein on which the Anaconda Co. is mining in the Mountain Consolidated mine, which has been worked up to the end-line of the Snoozer. In addition to the north vein, the company is drifting to the south, or discovery vein, both on the 1,200 and 1,500. On the 1,200, in the east drift, a fine body of ore four to six feet wide has been opened, and the east drift on the 1,500 is also in broken material, and the indications point to close approach to an orebody.

The report is that the Amalgamated Copper Co. will make extensions at its Washoe smelter in Anaconda, increasing its capacity, so that it will be able to treat all the ores that it is now handling and also those of the new Butte Coalition Co. and the United Copper Co., which will mean a suspension of operations at the smelter of the Montana Ore Purchasing Co., formerly the property of the United Copper Co., but now owned by Butte Coalition. The smelter is a comparatively small one and will not be able to handle all the ore that the Butte Coalition expects to mine.

Important improvements at the West Colusa and Leonard mines of the Boston & Montana Co. are being made. Work is in progress on a new steel gallows-frame at the shaft of the Leonard. The frame will be 152 ft. high from the collar of the shaft, the highest in the district. The new engine has not yet arrived but the foundation and building for it were finished some time ago. A station is being cut at the 1,500 ft. level of the West Colusa mine, and when that is finished the shaft, which is now down 1,600 ft. will be sunk 400 ft. deeper.

The discovery of rich copper ore at depths of 2,200 and 2,400 ft. in the Anaconda mine has prompted other companies to sink deeper, it having been demonstrated, beyond doubt, that there is apparently no limit to the depth at which good copper ore exists in the Butte district. The Anaconda Co. has opened three veins on the 2,400-ft. level, including the big one which was opened on the 2,200 about three months ago.

The Butte Copper Co. is shaping affairs for active work on the Emmet mines. The company will sink a three-compartment shaft 1,000 ft., the work to begin where the lessees quit some time ago, at a depth of 300 ft. At that point a large copper vein was cut.

The Butte & Bacorn Co. is making rapid progress on its three shafts north of Butte.

Mining Summary.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

ALASKA.

C. E. Darling of Nome reports a rich strike on property owned by E. W. Johnson of Seattle and other strikes in the Nome district. The claim owned by Johnson is one of the richest in the district. A $2 pan can be secured anywhere in the workings, and on bedrock pans have been taken out that go as high as $300. The new strikes are not confined to this, and all of the available boilers at Nome have been pressed into service, working the rich diggings. Nome has had a great winter of mining activity. The Portland Bench claim will clean up about $1,000,000 for the winter's operations, and the property owned by Thomas Noyes of Seattle will probably produce $100,000 this winter. Solomon has shown up better than at any time since the first operations were commenced in that section and will produce $2,000,000. The Mystery mine on Solomon creek, owned by George Grigsby and a man named Loudan, will produce about $100,000.—The Gold Run benches are showing up well, and the reports from the Kougarok give that section the best strikes that have been made there.—Another good thing about the district is the marked change in the political situation. For the first time in the history of Nome the marshal's office and the United States judge are working in perfect harmony. —The Nome dock has stood up well under the winter weather.

ARIZONA.

Cochise County.

(Special Correspondence).—A discovery of rich gold ore is reported from the Elizabeth mine, in Paradise district. Ore assaying 2,800 oz. silver and some gold has been encountered in a vein 3 ft. wide at a depth of 20 ft. The group, of which the Elizabeth is one claim, covers 240 acres, and is three-quarters of a mile north of the town of Paradise.

The Tombstone Consolidated Co.'s mill has been closed down for a few days lately, pending arrangements for carrying off a large accumulation of water. Water has been accumulating for some time in an old stope of the Toughnut mine, and the pressure became so great last week that the water broke through the bulkheads and practically flooded the 100-ft. level.

A two weeks' run of the Commonwealth mill, at Pearce, has resulted in the recovery of 14 bars of bullion, aggregating 1,950 lb. in weight. The bullion is one-fourth gold, the balance silver, which makes the clean-up worth somewhat over $100,000.

Tombstone, April 2.

Two miles west of Johnson are rich deposits of wolframite. Up to the present it was recovered in the placers by means of rockers and dry washers. A majority of the claims, mostly patented, are operated in a small way by two Eastern firms which deal in the metal —Stein & Bouricke, of the Primus Chemical Co., of Primus, Pa., and Charles & F. E. Canda, of the Chrome Steel Works Co., Chrome, N. J. D. F. Halderman, a resident of Russellville, is manager for both companies. The tungsten concentrate obtained by rockers is distributed over several miles of surface, and Mexican laborers working the rockers are paid 10c. per pound for it on the ground. An average workman will wash out 20 lb. or over per day. This concentrate is in size from a grain of corn to pieces several ounces in weight and from 65 to 75% wolframite, beside carrying scheelite in considerable quantities. The value of this product f.o.b. Cochise is from 17 to 20c. per pound, and shipments of several tons per month are made. The ore occurs in pure white quartz veins in the granite and is easily traced along the surface for several miles. The vein matter will go as high as 30% wolframite. No work to speak of has yet been done on these ledges, as it has been easier to get returns from the placers and from rich float, which is being crushed by hand crushers in a small way. There are several other parties who own claims on the belt who are shipping in small lots.

Gila County.

(Special Correspondence).—The shaft on the Copper Hill mine, at Globe, has reached a depth of 700 ft., where a station is being cut. As soon as this is completed sinking will be resumed. The company has recently been shipping 100 tons of sulphide ore daily to the Old Dominion smelter, and some silicious ore to the Green Consolidated, at Cananea. At the company's Black Hawk shaft sinking continues, and has reached a depth of about 400 ft. Another 100 ft. will be sunk before more crosscutting is done. The crosscut at the 300 level has disclosed a 12-ft. vein of hematite, carrying copper and silver.

Globe, April 2.

Graham County.

(Special Correspondence).—A persistent report is again in circulation, through the stoppage of the erection of the new converters at the smelter of the Detroit Copper Mining Co., to the effect that the converters of the company will be removed and reducing the matte to ingots will be done at Douglas. It is believed to be the intention of the Phelps-Dodge Co. to concentrate their reduction works at a central point, and, owing to the situation of Douglas, that town has been chosen as the point where the works are to be located. Should this move be made, no appreciable effect will be produced on the number of men employed in Morenci, as the other improvements under contemplation, and already started, will increase the payroll.

The work of excavating the old slag dump here will proceed, and it will be treated to recover the copper still remaining in the slag, and the excavation will be filled with new slag and waste from the other departments.

Another move for the improvement of Morenci and surrounding country is the standardizing of the Morenci Southern Railway from Guthrie to a point as near Morenci as possible. From the Morenci cañon to Morenci it is impracticable, nearly impossible, to make this road a standard gauge, on account of the heavy grades and sharp curves. In this cañon, in a length of one mile, the railroad makes four complete loops, crossing over itself each time. However, the broadening of the gauge to within a mile of the town will bring shipping prices to a lower point. The organization of the new companies in this locality will make this change necessary for the handling of supplies and machinery when they start operations, and the present route seems the only legitimate inlet to this district.

Should the persistent report that the Calumet & Hecla people are back of the option taken on the Home Copper Co. properties prove true, this will mean the erection of new works, and possibly a new road from the Frisco and Gila side of the county, and the opening up to competition the different industries that this district can easily support.

The Arizona Copper Co. is demanding the ground now occupied by the lumber yard of the Detroit Copper Co., which will mean the removal of the sawmill to some more convenient point. Whether this point can be found in Morenci or not remains for the company to decide, and little information is obtainable. Already the Detroit Copper Co. scrap-pile, which occupied Arizona Copper Co. ground, has been removed under their order, and thus the entanglement has been straightened out.

On Sunday morning, March 25, a switch-engine of the Detroit Copper Co., with a steel car of slag, got beyond control, and, after making two loops on the Morenci Southern Railway, jumped the track at the third loop, and engine and car were completely demolished. The engineer in charge escaped injury by jumping, while two brakemen were badly injured, although no fatalities will result.

There is greater activity in and around this district than ever before in its history, and from the number of deals now pending it is more than likely that the Clifton-Morenci district will close the year 1906 with more mines in operation than at any time in its history, and will be not far behind Warren district, in which Bisbee is situated. Engineers from all over the country, representing Eastern as well as Western capital, are securing all the ground available. During the past week a number of options have been taken on several of the most promising claims in the Copper Mountain district. Also, about 25 claims were bonded, it is thought, by the same people who own the Calumet & Hecla property in the Warren district.

A new whim is being installed on the property of the Home Copper Co., in Gold gulch. The country surrounding this property is being taken up for miles around and every day shows the hills full of prospecters and claim hunters.

The Detroit Copper Co. is excavating above the sawmill for a large set of railway scales.

Morenci, April 2.

Mohave County.

(Special Correspondence).—Superintendent Spargo, of the Enterprise mine, in the Big Hualapai mountains, 15 miles northeast of Kingman, has been exhibiting some strikes of lead ore encountered in the east drift of the mine on the 100-ft. level. The orebody is over 3 ft. wide, and it is believed that one-half of the vein is of shipping grade.

The Chloride Gold Mining Co., at Chloride, has made a shipment of ore to the Needles smelter carrying larger values than any heretofore made by the company. Regular shipments to the smelter will now be made.

Kingman, April 2.

The Kingman *Miner* reports a discovery of rich placer ground in the Cedar Basin country, to the north of Rioville. The gravel is said to be extensive and the gold coarse. Many people are rushing in there. The Cedar Basin is on the east side of the Virgin range, north of the Colorado river. Last year some good veins were discovered and worked there. The ore was found to be gold-bearing. H. Gentry, of St. Thomas, and M. Redman, of Kingman, were interested in mines in that section. Mr. Gentry at one time had his properties under bond, but the parties failed to take the option, owing to lack of water and its isolation. Now that placer gold has been found there, means will probably be found to work them.

Arrangements are being made for the purchase and erection of a concentrating mill on the Vanderbilt mine by the Cerbat Mountain Mining Co., of which J. Boyle is general manager. The mill will have a capacity of 25 tons daily. The ore now being taken from the lower level will not have to be treated, being shipped direct to the smelter. Ore from the upper levels will be milled, the concentrates calcined and amalgamated. In this way a saving will be made in freight charges.

S. Fields has gone to Stockton hill, where he will look after the construction of the mill on the Banner group for the Arizona-Mexican Mining & Smelting Co. The mill is to have a number of new concentrating tables and will handle 40 tons of ore daily. At present there are about 2,000 tons of ore on the dumps that will be concentrated. Shipments of ore are now being made from the mine daily, the stopes furnishing about one ton of shipping ore to three tons of mill stuff.

CALIFORNIA.

Calaveras County.

Articles of incorporation were filed the past week at Sacramento, by the Princess Tin Mining Co.

The directors and principal holders of the stock are C. F. Hines of San Francisco, G. O. Pearce of Murphy, and A. B. McCaw of Tonopah.

Inyo County.

O. Neylon has given an option on his mines northeast of Bishop to W. D. Clair. Mr. Neylon has been developing these claims for the last 15 years. It is estimated that at least $15,000 worth of development has been done. The mines lie in a compact group, situated a mile northerly from the Southern Belle, at a somewhat higher elevation and on the same mineral belt. Large ledges crop out on the Neylon ground, one measuring 100 ft. in width, and averaging $9 per ton in gold. Another is 23 ft. wide. Ore of much the same general character is found in all the claims—an oxidized quartz, carrying gold and free-milling. The walls show copper stains, and the same stain is found to a limited extent in the ore.

One large ledge crops out the full length of two claims, 3,000 ft. Assays taken along its entire distance range from $8 to $17. Near the lower end, across the claim is a natural cut 800 ft. deep. This ledge shows all up and down its face. A crosscut tunnel is in 650 ft. in this ground. At 400 ft. depth this tunnel struck a ledge 36 ft. across.

The situation is favorable for economical working. An ample water supply, fully protected by locations, is not more than three-quarters of a mile distant, and milling can be done at a cost low enough to make the values given profitable. The property is easy of access by wagon road, already built almost to the ground.

A. L. Wells and H. E. Parker have found rich silver-lead ore on locations made by them near and south of Redding cañon. There are said to be two ledges, 18 in. wide, traceable on the surface for a long distance. They also had some gold-bearing ore from the same neighborhood.

Modoc County.

(Special Correspondence).—The Hogue Mining district was organized March 29, 1906. The most important points of this new strike are located in the northeast corner of California extending into the northwest corner of Nevada. The first gold prospects in the district were found years ago and were mentioned in the field notes of the government survey. Active operations were begun last August by half a dozen prospectors at about the same time. Most of the work was done from one to three miles south of the Oregon and California line and 10 miles west of the Nevada line and resulted in the finding of five or six outcrops of ore.

Among the most important was a large dike on the main divide, west of Mount Bidwell and one mile south of the Oregon and California line. The dike is a light, porous porphyry full of blebs and small cyrstals, the lighter parts resemble pumicestone. On the surface the valuable mineral is concentrated in seams, and the soil on the hillside, below the dike outcrop, pans fine free gold all the way down the slope and along a small stream to Cave lake, a distance of one mile. Cave lake has no visible outlet. Samples taken from the surface cuts and shoots show from $4 to $40 gold per ton. This is a general statement derived from the results of 150 samples carefully taken and assayed. This dike has a general trend north and south and makes a contact on the west with a rock thought to be phonolite.

Last fall several prospectors were working three miles south of the dike on a small quartz vein in porphyry. Samples from one-half ton of sacked ore taken out last September assayed $207 per ton. About 94% of the gold was free. The vein was prospected to a depth of about 12 ft. before snow fell.

The best strike in the district was made on a contact a little to the east of the first two mentioned locations. The ore is mixed quartz and iron, with some spar, and specimens assay $700 to $2,000. This location is on comparatively flat ground, and the formation is not well understood. The discovery hole is 18 ft. deep. No ore has been shipped. The ore and formation here is described as resembling somewhat that at Goldfield, Bullfrog and the Kawich range. The ore here contains more quartz; otherwise they are nearly the same. The surface prospects well over large areas. Notwithstanding the show of free gold on the weathered talus, from the big dikes it is predicted the ore will become base with no great depth. However, the general appearance of the country is more inviting than the Nevada desert, owing to the presence of plenty of timber and water.

Two other discoveries a little south of the former three mentioned promise orebodies 4 to 12 ft. wide. The latter outcrops for 500 ft., assays showing from $12 to $25 per ton. The ore is comparatively hard and carries some galena and copper sulphides.

Specimens of tellurium ore from this location run from $150 to $300 per ton. These discoveries mentioned are located on the main divide, between Goose Lake valley and Surprise valley, at an altitude of 8,000 ft., and are best reached by following the south slope from Fort Bidwell, a distance of eight miles, by wagon road and trail.

Surprise valley is 50 miles long north and south, and has an altitude of 4,500 ft. Fort Bidwell is located at the extreme north end of the valley, and is well supplied with produce, grain, hay and fruit, is well timbered and watered. It may be reached from Reno by the narrow-gauge railroad to Madeline, and from there, 90 miles, by stage to Fort Bidwell.

The snow this season is from 6 to 10 ft. deep at the summit, which is quite unusual. The roads are bad, and it would not be advisable for those contemplating coming in to come until May 1.

Fort Bidwell, March 30.

Nevada County.

The Lecompton mine, near Nevada City, has been bonded to F. S. Mayhew of the Oroville Dredging Co. and E. P. Vandercook of San Francisco, who will open the property at greater depth. R. S Specht is superintendent.——A new mill and cyanide plant is to be in operation at the New York-Grass Valley mine in Grass Valley district.

Sierra County.

(Special Correspondence).—Work at the mine, owned by the Forest City Mining Co. (known locally as the Mabel Mertz mine), is being prosecuted under the management of H. B. McCormick. Last summer and fall the company erected a new boarding-house and other buildings on the property, and made numerous other improvements. The property is now well equipped, and possesses all of the facilities necessary to the proper operation of a placer or gravel mine. The main tunnel is being pushed ahead with two shifts. The company owns 6,000 ft. of the old Nebraska channel that it has been endeavoring to open up for some time. The first tunnel was found to be too high. A portion of the new tunnel was run through hard rock, and as it was necessary to run 1,500 ft. to get under the channel it has required considerable time. The Nebraska channel, wherever it has been worked, was rich, and the Forest City owners expect to be washing out gold within a short time. The necessary dumps, reservoir and other

apparatus for washing have been installed in order that no time will be lost in putting the mine in full operation as soon as the pay channel is opened up.

Downieville, April 2.

The Bullion mine, formerly the Collombo, is reported sold. It is situated close to the Sierra Buttes mine. The new owners are Los Angeles and San Francisco men, who have incorporated under the name of the Royal Quartz Mining Co. A contract has been let for the clearing out of the main tunnel, and plans have been drawn for a mill. It is estimated that the ore can be mined and milled for $2 per ton. The mine is a tunnel proposition. The ledge is from 3 ft. to 12 ft. wide, and mills $7 to $12 per ton.

San Bernardino County.

The new mining camp, 20 miles southwest of Needles, has been christened Sunrise. The district, since its first exploration some years ago, has been known as the Sunrise Mountain district, because it lies upon the north slope of the Sunrise mountains. Some years ago a shaft was sunk to a depth of 120 ft. on the Monumental group. From this shaft the present water supply for the camp is taken. The property has been idle, although parties have examined it, but there has always failed to be a transfer, although the reports show the property to have good orebodies. A little farther to the north and nearer Needles, a shaft was sunk some years ago but they failed to find payable ore.

A few months ago C. H. McClure discovered a quartz ledge. Hornings showed it to contain gold. Assays showed better results. This property was located and developed to a depth of 30 ft. Assays have run up into the hundreds of dollars per ton. The claim was named the Gold Dollar. The ledge was illy defined at the surface but with sinking it has developed from a ledge of a few inches to nearly 3 ft. at the bottom of the shaft. The ledge is well defined and dips into the mountain. The ore is white quartz, showing copper and iron stains and here and there particles of galena. There is nothing peculiar about the prospect except that the ledge seems to be divided near the center with a regular streak of finely pulverized, dark-brown substance several inches in width and it is this streak that has carried the higher values from the surface down. It was this property which brought the section to the attention of the public. There resulted an influx of prospectors, and many other good strikes have been made. Mr. McClure located several other properties, and has two groups, upon both of which good ore is found. A great amount of float quartz covers the north slope of Sunrise mountains and an examinatiion of the float shows a similarity in grade and character to that in the veins. Ernest Yarborough, a partner with Mr. McClure, is prospecting the claims and is making further discoveries daily.

M. L. Shackleford recently located some lead croppings. But little work has yet been done. The lead is associated with dark-colored spar. The croppings are regular so far as they can be traced. B. L. Vaughn, of Needles, is interested with Mr. Shackleford in numerous mining claims in the district.

W. A. Brooks, who is interested in properties in San Francisco district, near Vivian, in Mohave county, Arizona, has a camp at Sunrise and has opened a body of high-grade lead ore.

A. M. Wilkinson and T. Nay have a camp and a number of locations which show good croppings. Their work to the present time has been prospecting, as nearly everywhere else in the district, and they have uncovered some fine-looking ledges of lead ore, which they will develop.

Tuolumne County.

At the Los Angeles mine several miners are doing development work, the greatest difficulty being in keeping the water out.——Sinking at the Blackhawk near Soulsbyville is progressing under A. C. Glynn. A. A. Irish, of Los Angeles, is the principal owner.——The pump at the Louisiana mine near Carters has been running continuously. A large amount of old timbers and lagging have been encountered in clearing out the shaft. ——At the Spring Gulch good ore is being taken out, and this week the mill will be started. The owners anticipate a better clean-up than was made last time.——At the Grizzly and New Albany mines near Carters the company is doing development work, and the mill is kept busy day and night. There are 25 men employed at these properties.——At the Soulsby mine the Bagdad-Chase Gold Mining Co. has found excellent ore, but the mill will not be started until the mine has been more thoroughly developed. Over 40 men are employed. Preparations for unwatering the Davidson shaft are progressing. A six-inch Dow pump will first be used. After the water has been sufficiently lowered a 10-in. Cornish pump will be installed. This will be operated by means of power supplied from two new boilers. Work was commenced last week on a large gallows frame. At the Pennsylvania shaft a station is being cut on the 500-ft. level. The machinery formerly at the Bown mine, near Tuttletown, has been purchased and is being hauled to the Soulsby. W. Darlington is manager.

At the Maddox mine near Confidence, development shows the vein to be growing larger as the tunnel was driven ahead, and in the face of the adit last week the quartz showed ten feet wide milling ore, with a pay streak of high-grade ore. Everything is ready at the Confidence for the summer run. Wood has been cut and will be delivered as soon as roads are in condition to permit hauling. The cyanide plant will be started up early in April. The mill, which has also been idle since fall, is to begin crushing when fuel commences to arrive. Fifteen miners are at work.

Yuba County.

F. E. Wright, of Rackerby, says the Rackerby district is experiencing a revival. He has a bond on the Santa Rosa mine, one mile from the town of Rackerby, and has re-bonded it to R. W. Correll, of San Francisco, who has re-opened the old works, and intends to remodel the five-stamp mill and start the mine running this month if the weather will permit. Mr. Correll has also re-bonded from Mr. Wright the Abbott mine. Work will commence upon it at the same time as at the other property. The Santa Rosa mine has 800 ft. of tunnels in ore. The tunnels have been re-timbered and put in shape at a cost of about $800. The Abbott mine has two shafts down, respectively, 40 and 20 ft., but the ledge is large.

COLORADO.

Clear Creek County.

R. C. Bonney, president of the Chamber of Commerce and manager of the Sun and Moon mines at Idaho Springs, says that Idaho Springs is to experience one of the most active mining periods in its history.

Several important strikes have been made in the tunnels within the past few weeks. Sam Newhouse has decided to drive the Newhouse tunnel to completion. S. A. Knowles, who was in charge of the tunnel for a number of years, but who went to Montrose on the government tunnel, has returned and will again have charge of the work.

The tunnel is now into the Clear Creek-Gilpin belt over three miles, and an additional mile will take it under Quartz hill and the Eureka mine, the objective point of the tunnel.

To reach the tunnel from the Eureka mine in Central City a shaft over 1,600 feet in depth will be sunk.

The tunnel has not been advanced for over a year, but development work has been continued, and extensive lateral tunnels have been extended on both sides of the main tunnel. The Saratoga Development Co. and the Sun and Moon Co. are driving laterals eastward, while the Old Town, Gem, Addudel, Queen, Jackson Leasing and Orr have driven laterals to the west.

Mr. Knowles will have charge of the work for the tunnel company and he contracts the driving of the bore in two sections, the first of 4,000 feet, with privilege of 2,000 feet more, or until the Eureka vein is encountered at the greath depth. He will put three machine drills at work in the breast and push ahead with all speed.

The Lucania tunnel has struck good ore: the Two Brothers has opened an ore-shoot that is expected to produce largely. The Burns-Moore in the Ute creek section has crosscut a vein of high-grade gold and silver ore equal to anything that has ever come from its neighbor, the Lamartine; the Shafter vein in the Big Five Central tunnel is proving satisfactory; at the Hoosac its first vein was cut last week; the Rockford bore has passed through a cross vein of smelting ore.

Mr. Bonney expects to do diamond drill work on the Sun and Moon mines throughout their surface workings and also in the Newhouse lateral at a depth of 2,000 ft. In addition to prospecting his property with these drills, Mr. Bonney says that John Owen of the Saratoga Co. will connect the Newhouse lateral with the ninth level of the Saratoga mine. The Saratoga is filled with water, and, rather than begin a raise, with its great danger, Mr. Owen will use a diamond drill to connect the two points, which are but 400 ft. apart. R. B. Morton of the Jo Reynolds mine also expects to use a diamond drill for prospecting parallel veins.

A report is in circulation that the Terrible mine and mill is to pass to B. B. Lawrence of New York and J. H. Robeson of Georgetown. The Terrible property has been undergoing development during the past two years, with the result that a number of important discoveries have been made. During the past three years men have been cleaning out and re-timbering the levels and drifts. New pumping machinery was recently installed, and the water has been removed down to the deepest level. The shaft is now being sunk an additional 100 ft., and it is found that the ore-shoot is continuous.

Gilpin County.

Jones & Jones, of Central City, report a strike on the Perrin claim, in Russell gulch, south of the Topeka, at a depth of 150 ft. in the shaft, and have opened up four feet of milling ore, with six inches of a smelting streak which carries over $100 per ton. The ore shows copper and iron sulphide.

Chicago men have become interested in the Faraday Mining Co., owning the Faraday claim and having a lease and bond on the Argo, in Russell gulch east of the Alva Adams. The Argo is down 150 ft., but is credited with producing over $40,000 in gold. Grading has been started on the Argo for the erection of a shaft building, and Thomas Cudahy, manager, says that they will put up machinery capable of hoisting from 800 ft. The shaft will be sunk another 100 ft. as soon as machinery is placed.——Articles of incorporation of the A. A. Johnson Mining and Leasing Co. have been filed with A. A. and Clarence Johnson and Halsted L. Ritter of Denver as incorporators. This company has a lease and option on the Pendleton claim and mill site in the Russell district for three years. A new building is going up on the property and machinery is to be installed.——Sinking operations have been suspended temporarily at the Gibson shaft of the Esculapian Gold Mining Co. in lower Russell district, at a depth of 400 ft., while crosscutting north and south for the Gibson and Star of the West veins.

Lake County.

A large body of silver ore carrying 280 oz. of that metal and 30% lead per ton was opened up last week in the bottom of the Mammoth shaft, in Big Evans gulch, by the Citizens' Mining Co., under the management of A. B. Bohn. The ore was encountered under a cap of low-grade iron ore. The extent of the shoot has not been determined. The discovery was made in a new section of the camp, and means the extending of the known limits of the ore zone materially. St. Louis parties are heavily interested in the property.

Teller County.

Two of Cripple Creek's leading companies were overtaken by misfortune last week. One of the principal shaft-houses of the Portland Co. was destroyed by fire and the costly hoisting and other machinery seriously damaged, involving a loss of about $150,000, practically covered by insurance, and it is expected that the damage can be repaired in from three to four weeks; and since the company has two other shafts, the interruption to mining and development operations will not be serious.

The second misfortune promises to be more serious. In driving the drift at the 1,000-ft. level of the El Paso Co.'s mine a heavy flow of water was struck, which quickly drowned the pumps and rose to the level of the drainage tunnel from which it is flowing at the rate of nearly 3,000 gal. per minute. The El Paso management had felt secure against any such happening, for the reason that the 800-ft. level has been dry from end to end, although over 200 ft. below the general water level of the Cripple Creek district. It has been assumed that a certain dike acted as a barrier, and this was depended on to protect the workings to the greater depths. It is possible that a water pocket only has been tapped, in which case the workings can in time be pumped out; but if the flow comes from one of the main water courses of the district, the situation is a serious one. In the latter case it is quite possible that the economical draining of El Paso's lower levels may have to await the construction of the new drainage tunnel. There are ore reserves and unexplored territory above the water level, but with the lower workings remaining flooded the production of the property must be largely curtailed.

Brown & Co., who for the past year has been treating the tailing dump in the National mill, has secured a lease on the tailing dump of the El Paso mill. As soon as the machinery can be repaired the work of treating the tailing will begin. The dump contains 5,400 tons, and will afford six months' employment. The National dump consists of 16,000 tons. The sand is to be treated by a leaching cyanide plant.

IDAHO.

Shoshone County.

(Special Correspondence).—The Bunker Hill & Sullivan Mining Co. is planning to re-work its tailing piles. The company recently installed a small plant upon its dump at Kellog, and the process seems a success, although according to Manager Stanley E. Easton, the experiments are as yet incomplete and no definite results have been attained. The plant is operated by three men, and consists of jigs, which separate the lead ore from the lighter waste. The product from the jigs is then ground fine and reconcentrated in the usual manner. The company has on its dump 1,000,000 tons of tailing, and if the experiment proves successful, a large plant will be installed.

Wallace, April 1.

R. B. Bohannon has been granted the privilege by the city council of Wallace to establish a plant for working tailing in the south fork of the Cœur d'Alene river through that city, for which he is to pay $450. Mr. Bohannon is to complete his work within two years, if possible—he asked for three—and at the expiration of that time, if he is not through, he is to have the first option to continue another year. George Banister, who for some time has operated a tailing plant above town, bid for the permission; but his bid was $50 less than that of the successful applicant. The working of tailing along the streams upon which concentrators are situated has grown to be an important industry in this country. It is claimed that 10% of the values get away. By damming the stream at intervals, allowing the mineral particles to settle, and by installing a system of jigs, it is claimed a good portion of this lost wealth can be saved. Official returns show that of the output of the Cœur d'Alene last year, the five tailing plants produced net over $25,000. In the river the tailing deposit is from 4 to 7 ft. deep, and in places rich.

MISSOURI.

Jasper County.

Rich strikes have been made on the zinc properties of the International Power Co. within the last few days, and the representatives of this company are purchasing all the surrounding properties. Ground has been broken for the largest concentrator in the district, and shaft-sinking begun for three double compartment shafts. All adjacent properties have increased in value since these strikes were made.

MONTANA.

Beaverhead County.

H. H. Armstead, who is interested in the Silver Fissure Mining Co., which is handling the Polaris property, arrived in Dillon this week from New York, is now at Redrock looking after business for the company. Work is to be immediately resumed at Polaris and installation of a smelting plant is to be pushed. A good deal of the necessary machinery for the smelter is at Polaris. The work on the road, over which traction trains will be run, will be resumed as soon as the frost is out of the ground.

Broadwater County.

New development at the Custer group, near Winston, has been pushed, the old shaft having been sunk 200 ft. and a new shaft sunk an equal distance, and crosscutting commenced. New machinery has been placed and the shipments, beginning April 1, will be doubled, reaching 3,000 tons a month.

J. P. Woolman and Mr. Edwards, of Helena, have purchased the dump of the Bald Mountain mines from Thomas Cruse and will work them with a new 150-ton cyanide plant. There are about 75,000 tons of tailing which assays from $3 to $7 per ton. Work will be commenced on the new plant immediately.

The East London Mining Co., recently incorporated, will develop properties four miles south of Helena.

Fergus County.

There will be much activity in the Zortman district in the Little Rockies this season. The Fergus Co. has 10 claims on the west side and has done extensive development work, and will put a 100-ton plant on the property this season. The Ruby Gulch, which has been a large producer, sending in the vicinity of $20,000 per month to the Helena assay office, has, during the winter, enlarged its plant, beside doing extensive development work. It is reported that the Pappoose Co., in the same district, is contemplating the building of a plant.

Jefferson County.

During the week representatives of the German stockholders of the Cataract Mining Co., whose mines, smelter

and concentrator are near Basin, have been examining the properties. The mines of the Cataract Co., principal among them being the Bullion, are producing more than can be handled by the reduction works.

There is much activity in the old Wickes-Corbin district this winter, and more properties will be worked there than in many years before. Martin Mulvahill, who recently secured control of the Minnesota, has sunk the old shaft to 275 ft. and will sink another 100 feet.

Park County.

At Cooke City the transformed Republic smelter has been bought by the Buffalo-Montana Reduction Co., which is to treat ore from the Great Republic group.

D. Noble, one of the few pioneers of the camp, says that G. B. Allison and associates, of Seattle, will construct a 25-ton smelter one-half mile out of Cooke City, on Soda Butte creek, which will treat custom ore. In proximity to the Daisy group, Prof. Tanzer and associates, of Seattle, are erecting a smelting plant, consisting of amalgamation, concentration and smelting for custom ore. The National Park Gold Mining Co., a Montana organization, with home office at Great Falls, is preparing to take advantage of the custom treatment. Z. Daniels and associates will supply the iron-gold flux — in fact, it is reported that 60 properties are engaged in preparation for the coming year's active bullion production. At no time since the '80s has there been such substantial evidence that the Cooke City camp will be one of the great mineral producing camps in the northwest. There are 400 souls in the camp — 50 women and children and 350 miners.

NEVADA.

Esmeralda County.

A discovery of cinnabar is reported from Goldfield in the Goldfield-Brooklyn mine, in the northeast corner of the district.

In Bullfrog district, on the Transvaal claim, 15 miles northeast of Beatty, it is reported that surface prospect samples assay from $30 to $182. For 50 ft. in width and 200 ft. in length the pay-shoot has been determined.

Lincoln County.

(Special Correspondence).—Considerable activity has been occasioned in this camp by the visit of L. L. Patrick and party from Goldfield; also Matt Hoveck, superintendent of the Montgomery-Shoshone mine of Bullfrog. Both parties examined several properties in the district and acquired interests in the Cyrus Noble extension. They have also taken bonds on several other properties.——At the Le Roy the entire shaft is being retimbered. In the drift on the third level a large body of free-milling ore has been cut east of the main shaft. A new electric pump of 25,000 gal. capacity is to be installed and sinking will be continued.——The Quartette Mining Co. has let a contract to sink a vertical shaft 250 ft. on their Bay State claim.——The mill of the New Era Mining Co. resumed operation this week on ore from the south raise. It plates $20 per ton.——The Southern Nevada Co. mill will resume operations during the week. The mine has been developed to the 250-ft. level, but work has discontinued on account of water. Ore is now being taken out from a shaft sunk on the east-west vein.——The bottom of the main shaft of the Searchlight Treasurer is now all in ore. This shaft, which was started at a 45° dip, following the ledge, is straightening up. Considerable copper-stained quartz has been struck at 50 ft., which runs $42 per ton.——The Parallel shaft is nearing the 500-ft. level. Superintendent T. D. Forney has a full force throughout the mine, and in addition to sinking, drifting and crosscutting is being done. ——The shaft of the Venus is all in ore; contracts have been let to sink to the 400-ft. level. Stations are to be cut at the usual intervals, and a 15-h. p. hoist will supplant the whim now in use. Drifting east and west will be continued on the 100-ft. level to determine the length of the orebody.——While sinking for water on the Waterspout claim, close to town, considerable copper-stained ore, heavily mineralized, was struck at a depth of 190 ft. Drill samples assayed $44.80 per ton in gold and silver.——At the Cyrus Noble mine the new mill is reported giving excellent results and preparations are being made for a new 40-h. p. hoist, upon the arrival of which the force of 60 men now employed, will be materially increased.

Searchlight, April 1.

Lyon County.

The Federal Co., in the Como district, has men employed in preparing for an active campaign. Enough ore is blocked out to keep the milling plant in operation the next four years. The present plant consists of eight stamps and two roller crushers, and 10 more stamps are to be added, giving a daily capacity of 75 tons. The plant is operated by electric power from the plant at Floriston, on the Truckee river.

Nye County.

(Special Correspondence).—There is an excellent opportunity for a custom mill in Manhattan camp. All of the mines that are being worked seriously excepting the Manhattan Consolidated, are in the hands of lessees, who ship their ore at heavy expense. There are water and fuel to be obtained, and a 10-stamp custom mill would find more than it could possibly do at a good liberal price for treatment. The ores are thus far free milling, and apparently easy of treatment. One set of lessees has made a good clean-up by scraping up the loose float and débris that had naturally drifted down upon it from a claim on the hillside above. Good reports continue to come in from Round Mountain and Jefferson cañon. The hills hereabouts are full of prospectors, though prospecting is slow and uncertain owing to the north slopes, and some of the south exposures as well, being covered with snow.

The ore deposits are found to conform closely to the bedding planes of the enclosing rocks, and although sulphides are scarce in the district as yet, the porous, honey-combed iron gossan indicates what may be anticipated in depth. The prices asked for property are naturally out of all proportion to their present real value, but the speculators who are in camp watching developments seem willing to take a chance. There has thus far been no trouble in floating stocks in Manhattan mines, and the public, in this way, is furnishing the sinews of war to develop Nevada's newest gold camp.

Manhattan, April 2.

A new strike is reported at Round Mountain, about six miles east of Manhattan.

White Pine County.

The Ely Central Copper Co., of Philadelphia, capital $12,000,000, has been incorporated at Dover, Del., to acquire mines of copper, gold, silver and other metals and ores to mine, mill and refine the same for market. John W. Woodside and Frank M. Wirgman, of Philadephia, and B. A. Hazel of Smyrna, Del., are the incorporators.

OREGON.

Coos County.

The Wolverine & Western Development Co. was organized at Laurium, Michigan, last week, the promoters being Calumet and Laurium people. The incorporators are J. T. Fisher, F. J. Kohlhaas and J. Vivian, Jr. The company is organized under the laws of Arizona. The property is on the boundary between Douglas and Coos county, and consists of eight full claims. The calculation is that six months will be required to determine the exact conditions and outline a future policy for the undertaking. The property is opened by a tunnel penetrating two veins 60 ft. below the outcrop.

SOUTH DAKOTA.

Custer County.

On the Detroit claim, of the Ivanhoe company, near Custer, an open cut has been run 64 ft., showing a face 18 ft. high on the three-foot vein. The vein is running toward the Chilkoot orebody. Assays show an average of $15 per ton, and it is possible to handle this grade of material at a profit. The company is building a trestle and chute from this opening to the mill. The east drift from the 200-ft. level of the main shaft is being pushed to tap the Detroit vein. The mill is being run partial capacity, its operation being curtailed on account of a shortage of water.

Lawrence County.

In Deadwood gulch below Central City, and below the early-day sites of not less than 15 small mills is a large deposit of mill tailing. A company has been recently organized to exploit these deposits, the Golden Placer Mining, Milling and Cyanide Extraction Co., T. E. Corkhill, of Central City, secretary and manager.

Five shafts have been sunk to bedrock, showing the deposits of tailing to be from 10 to 30 ft. thick. Tests in a small mill have been made. The company owns a 100-ton mill, and proposes installing a duplicate of it, and a cyanide plant.

UTAH.

Salt Lake County.

The new Garfield smelters have begun receiving ore. The first carload of concentrate from the Utah Copper Co.'s Bingham mill, was delivered at the smelter last week. Later another lot of concentrate from the New-house-Cactus mill arrived, and this was followed by crude ore from the Boston Consolidated mine of Bingham. The bins at the new smelter will hold about 25,000 tons. By the time the first unit of the plant is ready to be blown in, about June 1, the bins will be filled.

WASHINGTON.

Ferry County.

(Special Correspondence).—The annual meeting of the stockholders of the Pearl Consolidated Mining Co. was held at Spokane, Wash., March 20, when the following board of directors was elected for the ensuing year: Charles P. Robbins, Dayton H. Stewart, Charles Theis, Leo H. Long and Frederick Burbidge. The executive officers are: C. P. Robbins, president and treasurer; D. H. Stewart, vice-president; Charles Theis, secretary. According to President Robbins' report, operations at the mine were resumed Oct. 23, 1905. When the mine was shut down the Lone Pine shaft had attained a depth of 163 ft., and had just passed through a 4-ft. vein, which assayed $3 per ton. The shaft has been sunk an additional 26 ft., the last 16 ft. being in No. 2 vein, which at this point is 7 ft. wide and assays $5.50 per ton. A station was cut at 182 ft. from the collar of the shaft and drifts run southerly 20 ft. and northerly 225 ft. on the vein, to within 45 ft. of the east side line of the Lone Pine claim. In the south drift 7 ft. of ore assays $7.65 per ton. The first 150 ft. in the north drift varies from 4½ to 10 ft. in width, assaying $4.67 per ton. From this point to the face of the drift it averages about the same width and assays $7.06 per ton, the face assaying $4.85 per ton. A raise from a point in the north drift 210 ft. from the shaft is going up to meet a winze being sunk from the tunnel level. The raise is in ore varying in width from 4 to 6 ft. and assays from $7.60 to $10.52 per ton. Surface improvements consist of a 400-ft. tramway, built to hoist wood and material from the railroad to the shaft; installation of boiler and small compressor and housing same. In January the company purchased a 35-h.p. boiler, 2-drill compressor, two Rand drills, an 8-h.p. hoist, 500 ft. of 2½-inch pipe, blacksmith outfit, fittings, etc., from the Princess Maud Gold Mining Co. for $750. This plant was put in commission on Feb. 12, and since then the cost of development work has decreased 30%. The tramway, with little addition, can be converted into a gravity tram to lower ore to the railroad, as well as to get up supplies. In December 174 5 tons of ore were stoped at a cost of $729.71, smelter receipts from same being $2,046.84. In February there were shipped from second class dump (accumulated from early workings) 310 tons, returns from the smelter being $510.71; cost to load, $86, netting $414.71. There are at the smelter 125 tons that should net $700. As soon as connection is made between the raise and winze the mine will be in condition to stope, and with a market for the ore the mine should be self-supporting.

Republic, March 30.

FOREIGN.

CANADA.

BRITISH COLUMBIA.

Yale District.

From a hole in a large ledge of quartz on the Never Slip property, four miles east of Grand Forks, rich free-gold quartz was blasted out one day last week. As a result the country around the Never Slip has been staked for miles. It is reported that the ledge is 20 ft. in width and over 1,500 ft. in length. It is owned by Simpson, Stewart, Hutton & Murphy, of Grand Forks.

Work has been started on the site for the blast furnaces and warehouse of the British Columbia Copper Co.'s new smelter at Greenwood. Tunneling has begun under the dumps, so that the slag can be removed more rapidly. W. H. Thomas, formerly of Bingham, is general manager. As the work proceeds the narrow-gauge tracks will be replaced by broad-gauge tramways, and instead of the present five-ton slag pot, a 25-ton pot will be used. The work on the new ore-bins will be rushed as fast as possible. The timbers of the old ones are being used to support the tracks over the tunnel. The water tank is being removed. Work will soon begin on the new building which will accommodate the machine and blacksmith shops. These will be fully equipped. All the mechanical appliances of the plant will be electrically driven. The three new furnaces will be much larger than the present ones. The ones now in use are 12 ft. long by 28 in. wide. The new ones will be 20 ft. long by 48 in. in width.

MEXICO.

Chihuahua.

For the past two years the Cia. Metalurgica de Torreon has been buying mining properties, and the last few months has shown an increase in activity in that direction, particularly in the Santa Barbara section of the Parral district, where they have bought several properties recently. The Torreon plant is amply supplied with good lead-fluxing ores from its various mines. Since the combination which existed for two years between the Torreon plant and the trust expired the miners have had a much better deal from the smelters, and the former concern has been gaining popularity. It has been reported for some time that the Torreon smelter is to have copper stacks put in. The reports of its recent mine purchases includes some copper properties.

Books Received.

'Electric Power Plants,' by Norman H. Schneider, is a book which will find a ready sale among those desiring a general and comprehensive knowledge of electricity and its application. It contains chapters on standard wiring; direct and alternating-current generators, motors and motor starters; testing and measuring instruments; the storage battery; the incandescent lamp, and general engineering notes; 290 pages, 203 illustrations. This book will be sent on application by the MINING AND SCIENTIFIC PRESS on receipt of the price, $1.50, in cloth: Spon & Chamberlain, publishers, 123 Liberty street, New York.

'Valve Gears for Steam Engines,' is the title of a valuable treatise on this subject (being the second edition) by Cecil H. Peabody. The object of this work is to give to engineering students instruction in the theory and practice of designing valve gears. Graphic methods are employed for this purpose, the author's idea being to give the student a thorough knowledge of the principles of valve gear construction. Common and well-known methods and processes have been used in most cases, and novelty has been rather avoided than sought. Some things, however, are original; for example, the combination of a skeleton model with construction for laying out link-motions, and other irregular or complicated gears, and several examples of double valve gears, the latter being introduced to show the scope of the methods used. This useful book will be sent on application to the MINING AND SCIENTIFIC PRESS for $2.50. John Wiley and Co., publishers, 43 East Nineteenth street, New York.

The latest treatise on cyanide is that of Robine, Lenglen and Le Clerc, under the title, 'The Cyanide Industry, Theoretically and Practically Considered,' translated from the French. It deals with the chemistry of cyanogen and its derivatives, reviewing all of the numerous compounds of cyanogen with other elements, particularly the metals, also its compounds with oxygen and sulphur. Part II is given to the present condition of the cyanide industry. Part III is devoted to the cyanide industry as applied commercially in the manufacture of cyanogen compounds. Part IV will interest those who are concerned in the cyanide process of extracting gold from its ore, as it reviews the cyanide situation throughout the world, and goes into the chemistry of the process in a painstaking manner. In an appendix is given a digest of U. S. patents relating to the cyanide process. This work will be sent by the MINING AND SCIENTIFIC PRESS upon the receipt of the price, $4. John Wiley & Sons, publishers, 43 East 19th street, New York.

Trade Treatises.

The C. W. Hunt Co., of 45 Broadway, New York, has issued Catalogue 063, 'Coal Handling Machinery,' which describes with numerous illustrations their machinery and methods of handling large amounts of coal at minimum cost.

The Compressed Air Machinery Co., of San Francisco, have issued a neat brochure descriptive of the Word Bros.' drill maker and sharpener. It is clearly and handsomely illustrated, and the operation of the machine fully described.

Personal.

ARTHUR WINSLOW is at Telluride.

AUGUST RAHT is in Salt Lake City.

BERNARD GILPIN is on his way to Mexico City.

MARTIN J. HELLER has returned to San Francisco.

GEORGE W. MAYNARD is expected in San Francisco.

CLARENCE EDSALL, of Colorado Springs, is visiting San Francisco.

EDWARD SKEWES, on his return from Mexico, is now at Minneapolis.

GELASIO CAETANI is with the Bunker Hill & Sullivan mine, at Wardner, Idaho.

J. P. EVANS, of the Colorado Iron Works, Denver, was in San Francisco this week.

CARL HENRICH is opening up a mine at Metasville, in Wilkes county, Georgia.

D. E. WOODBRIDGE has been at Clifton, Arizona, in the interest of THOS. E. COLE.

RICHARD M. JONES represents the Venture Corporation, Ltd., at Goldfield, Nevada.

A. P. KENNEDY is manager for the Hillabee Gold Mining Co., at Yates, in Alabama.

GEORGE W. MABEE, JR., formerly of Central City, Colo., is now at Tonopah, Nevada.

LEONARD D. SIVYER, of Los Angeles, is examining mines in the new gold fields of Nevada.

J. MORGAN is superintendent of the South Kalgurli mine at Kalgoorlie, Western Australia.

R. L. ROWE is on the staff of the Regina mine, on the Lake of the Woods, in Ontario, Canada.

FREDERICK GRUNDY has returned from the examination of mines in Arizona to Los Angeles.

R. H. HUGHES has been appointed chief engineer of the Dharwar Gold Mines, Ltd., in India.

J. W. STEARNS, of the Mountain Electric Co., Denver, is taking a holiday at Santa Barbara.

F. P. RODDY, secretary of the Poker Flat Gold Mine Co., Sierra county, Cal., is in San Francisco.

H. H. ARMSTEAD has returned from New York to the Silver Fissure mine at Polaris, Montana.

SARAT C. RUDRA, of Calcutta, India, is examining mines in Sierra county for New York parties.

R. S. OLIVER is now superintendent of the Addie Mining & Smelting Co. at Silver City, Idaho.

CORTLANDT E. PALMER is in Mexico, making his official visit to the Guggenheim mining properties.

J. BOYD AARONS is now superintendent of the Boulder Deep Levels mine at Kalgoorlie, Western Australia.

W. D. PINKSTON, superintendent of the Sierra Buttes mines, has returned to the mine from San Francisco.

J. W. FINNEY, superintendent of the Telegraph mine, has returned to Downieville, Cal., from San Francisco.

GEORGE MCGEE, manager of the Sovereign Gold Mine Co., has returned to his home at Fruitvale, California.

FRANK H. PROBERT, of Los Angeles, is now examining mines in the Suhuaripa district of Sonora, Mexico.

H. P. GARTHWAITE, managing director of the Butters Salvador mines, arrived from Salvador on the *Curaçao*.

W. J. LORING now resides at Melbourne, as general manager, in Australia, for Bewick, Moreing & Company.

FRED PERRYMAN has been appointed superintendent of the Sierra Alta gold mine in Sierra county, California.

ROBERT B. GLEISBERG, late manager of the Associated mines, at Kalgoorlie, is on his way from Paris to Mexico.

M. F. BURKE has returned to Boston from a visit to the mines of the Black Peak Co. at Hillsboro, New Mexico.

S. A. KNOWLES has returned to Idaho Springs, from Salt Lake, to again take charge of the Newhouse Tunnel.

H. B. MCCORMICK, superintendent of the Forest City Mining Co., has returned to the mine from San Francisco.

ARTHUR DICKINSON, of Charleton, Dickinson & Co., is in Norway, as consulting engineer to the Brustad Mines, Ltd.

A. CHESTER BEATTY, accompanied by MRS. BEATTY, sailed from New York on April 2, for a holiday tour in Italy and France.

E. L. BALLOU has left Argo, in Shasta county, to proceed to Pony, in Montana, as superintendent of the Garnet Company.

H. L. PAYNE, of The Wade & Wade Co., Los Angeles, is in Mexico examining a quicksilver property for Eastern capitalists.

A. D. LAWRY, assistant superintendent of the Combination Mines Co., at Goldfield, Nevada, was married this week at San Jose.

HERBERT M. TOD and PERCY HAGERMAN, of Colorado Springs, are investigating old tailing dumps in Amador county, California.

H. MORTIMER LAMB, editor of the *Canadian Mining Review*, has recovered from an attack of typhoid and will shortly be 'on deck' again.

THOMAS COX, late manager of the Morning mine, at Mullen, Idaho, is now in charge of the mines of the Nevada Consolidated Copper Co., at Ely, Nevada.

METALS.

SILVER.—Per oz., Troy: New York, (by wire), bar silver, 64½c. per fine ounce; San Francisco, 64½c.; London, 29 1-16d. (standard ounce, 925 fine); Mexican dollars, 50@51c., San Francisco; 49¾c., New York.

COPPER.—New York (by wire, average for week ending April 5), Lake, 18.62@18.75c; Electrolytic, 18.25@18.50 Casting, 18.00@18.25c. per pound. Mill copper plates, $21; bars, 21@24c. London: £84 5s. spot per ton.

LEAD.—New York (by wire, average for week ending April 5), $5.35 per 100 lb; San Francisco, pig, 5.70@6.60c. per lb.; pipe 7¾c.; sheet, 8¾@9¾c.; London: £15 10s. ℔ long ton.

SPELTER.—New York (by wire, average for week ending April 5), $6.10@6.15 ℔ 100 lb.; London, £25 2s. 6d. ℔ ton; San Francisco, ton lots, 7c.; 100-lb lots, 7¾c.

TIN.—New York, pig, $38.00@38.50; bar tin, ℔ lb., 42¼c.; pig, 39c. London, £173 5s. 0d.

PLATINUM.—San Francisco, crude, $18.50 ℔ oz.; New York, ingot, nominal, $23@25 ℔ Troy oz. Platinum ware, 75@$1.00 ℔ gram.

QUICKSILVER.—New York, $40.00@$41.50, large lots; London, £7 7s 6d.; San Francisco, local, $39.00 ℔ flask of 75 lbs.

NICKEL.—New York, 48@60c ℔ lb.; ton lots, 40@47c.

ZINC.—Metallic, chemically pure, ℔ lb., 50c.; dust, ℔ lb., 10c.; sulphate, ℔ lb., 4c.

BABBITT METAL.—San Francisco, No. 1, 10½c.; No. 2, 8c.; No. 3, 7½c.; extra, 17½c.; genuine, 32½c.; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 23.50c; San Francisco, Plumbers', 100-lb. lots 19.75c.

ALUMINUM.—No. 1, 99%, small lots, 35@38c. ℔ lb.; 100 lbs., 35c.; 1000 lbs., 34c.; ton lots and over, 33c., Pittsburg. No. 2, 90%, small lots, 34c.; ton lots and over, 31c, Pittsburg.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, $18.35; gray forge, $17.85; San Francisco, bar, 3½c. ℔ lb., 3¾c. in small quantities.

STEEL.—Bessemer billets, Pittsburg, $27.00 open hearth billets, $28.00; San Francisco, bar, 7c to 13c ℔ lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 8¼c.; less than 500 lb., per lb., 8¾c.; in 25-lb. tin pails, ½c. ℔ lb. above keg price; in 1 and 5-lb. tin cans, 100 lb. per case, ½c. per lb. above keg price. Dry Lead.—In bbl., 1 ton and over, 8c.; do. in kegs, 8½c.

LIME.—Santa Cruz, $1.35 country, $1.25 city ℔ bbl.

CEMENT.—Imported, $3.00@4.00 ℔ bbl.; California, carload lots, $1.80 f. o. b. at works; small lots, $2.10 ℔ bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

LUMBER.—(Retail): Pine, ordinary sizes, $24.00@25.00; extra sizes higher; redwood, $28.00@30.00; lath, 4 feet, $4.50@5.00; pickets, $21.00;shingles, $2.50 for No. 1, and $2.25 for No. 2; shakes, $13.50 for split and $15.00 for sawed; rustic, $28.00@35.00.

NAILS.—This week the basic prices are: Wire, $1.85; Cut, $1.75. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d, Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4d and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

GENERAL SUPPLIES.

ANTIMONY.—New York, per quality, 17@18c; San Francisco, 1000-lb. lots, 16c; 300@500-lbs. 12c, 100-lb. lbs. 12c; 100-lbs lots, 13c.

BONE ASH.—Extra No. 1, 6c ℔ lb; No. 1, 5c½.

BORAX.—Concentrated, 9½c ℔ lb; powdered, 10c; fused, 25c; crystal, refined, 8c.

CANDLES.—Standard Oil Co.—Electric light, 16 oz., 11c; 14 oz., 9¾c; 12 oz., 8½c; 14 oz., 7¾c; Hotel, 12 oz., 9c; Granite (mining), 16 oz., 11½@11½c; 14 oz., 10@10½c; 12 oz., 9½@9½c; 10 oz., 8½c; Paraffines, White, 1s, 2s, 4s, 6s, 10½c; 12s, 11c; colored, 1c higher; Radiant Paraffines, 4s, 6s, 14 oz., 9½@9¾c; 10 oz., 7¾c.

CAPS.—3x, $5.50@6 per 1000; 4x, $6.50@7; 5x, $8@8.50; Lion, $9@9.50, in lots not less than 1000.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1**, 50%, carload lots, 11½c; less than one ton, 13¾c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2**, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

CHEMICALS.—Cyanide of potassium, 98%–99%, jobbing, 23@24c ℔ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 3@3½c ℔ lb.; caustic soda, in drums, 3@3½c ℔ lb.; Cal. s. soda, bbls., $1.10@1.20 ℔ 100 lbs.; sks., 90c@$1.00; chlorate of potash, 12@13c; nitrate of potash, 6¾@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2¼@2½c; flour sulphur, French, 2¾@—c; alum, $2.00@2.25; California refined, 1¾@2c; sulphide of iron, 8c ℔ lb.; copper sulphate, 6½@7c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66% B, 1¾@2c ℔ lb.; nitric acid, carboys, 8c ℔ lb.

COAL.—San Francisco, coast, yard prices to dealers: Wellington, $7.50; Seattle, $6.50; Coos Bay, $5.50; Cargo lot, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $14.00; Cannel, $8.50; Rock Springs, $8.50, long ton; Colorado Anthracite, $14.00. Coke, $11.50 per ton in bulk, $13.00 in sacks; Sunnyside, $8.50, long ton.

OILS.—Linseed, boiled, bbl., 56c; cs., 61c; raw, bbl., 54c; cs., 59c; Lucol oil, boiled, bbl., 48c; cs., 53c; raw-bbl., 46c; cs., 51c. Kerosene—Pearl, per gal., 17c; Astral, 17c; Star, 17c; Extra Star, 20c; Eocene, 19c; Elaine, 26c; Water White, in bulk, 10½c; Mineral Seal, iron bbls., 18½c; wooden bbls., 21c; cs., 24½c; Mineral Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 15½c, do., cs., 22c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 12½c; do., in cs., 19c; Lard Oil, E. W. S., bbl., 65c; cs., 70c; Neats-foot Oil, pure, bbl., 63c; cs., 78c; Sperm, crude, 53c.; Natural White, 68c; Bleached, do., 57c; Whale Oil, cs., 57c.

FIRE BRICK.—Domestic, carloads ℔ 1000, f. o. b., factory square, $25.00; soap and split, $22.50; arch and wedge, $27.50; skewback, $30.00; circle, $32.00.

BISMUTH.—Subnitrate, ℔ lb., $2.10.

CHROMIUM.—90% and over, ℔ lb., 80c.

FIRE CLAY.—Domestic, ℔ ton 2000 lbs. in 125-lb. bags double, and dry ground, f. o. b., factory, $8.50.

FUSE.—Triple tape, $4.00 per 1000 feet; double tape, $3.55; single tape, $3.10; Hemp, $2.85; Cement No. 2, $3.10; Cement No. 1, $2.75, in lots of 3000 and up.

LITHARGE.—Pure, in 25-lb. bags, 9½@10½c ℔ lb.

MAGNESIUM.—Pure, N. Y., $1.60.

MANGANESE.—Black oxide, ℔ lb., 2¾@4c.

MERCURY.—Bichloride, ℔ lb., 77c.

MOLYBDENUM.—98@99% N. Y., $1.75 ℔ lb.

PHOSPHORUS.—American, ℔ lb., 70c.

RED LEAD.—500 lb. and over at one purchase, ℔ lb., 8¼c.; less than 500 lb., 8½c.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 54c.

SODIUM.—Metal, ℔ lb., $1.

TUNGSTEN.—Best, ℔ lb., 90c.

URANIUM.—Oxide, ℔ lb., $3.40.

Commercial Paragraphs.

AT the recent annual meeting of the Wellman-Seaver Morgan Co., of Cleveland, Ohio, the office of general manager, which has been vacant since the death last June of Mr. Charles H. Wellman, was filled by the election of Mr. S. H. Pitkin, whose present title will be first vice-president and general manager. Otherwise no changes were made in the officers of the company.

THE Stromberg-Carlson Telephone Mfg. Co., Rochester, N. Y., report having closed a contract with the Kinloch Long Distance Telephone Co. of St. Louis, Mo., for 10,000 central energy telephones. This is the first order the Kinloch Co. placed for new telephones to be used in conjunction with the 17,000 line switchboard now being installed by the Stromberg-Carlson company.

THE Blaisdell Co., of Los Angeles, has closed a contract with the Compania Minera Las Dos Estrellas, S. A., for the equipment of its new 120-stamp mill, El Cedro, with machinery for the Blaisdell system of handling cyanide sand, for which will be required two Blaisdell excavators, four distributors, one tripper and one tailing stacker; also, an extensive system of Robins conveying belts. The Dos Estrellas plant is near the 100-stamp mill of the El Oro Mining & Railway Co., Ltd., in the cyanide plant of which the Blaisdell system has been in operation for a year, giving satisfactory results.

THE Colorado Iron Works Co. of Denver, Colo., recently entered an order for a 100-ton concentrating mill, complete erected, for the Mowry Mines Co., Patagonia, Ariz. The equipment includes Colorado Iron Works' standard rolls, impact screens, simplex tables, vanners, spitzkasten and settling cones. This company also reports the sale of impact screens to the Annie Laurie Mining Co., Kimberly, Utah; Mine La Motte Development Co., Missouri; the Bertha Mineral Co., Pulaski, Va.; the Hermosa Copper Co., Hanover, N. M.; and bullion cars to the Great Western Ore Purchasing & Reduction Co., Keeler, California.

Compressed Air announces that with its issue of May it will appear in enlarged form and under new management. Hereafter it will be published by the Kobbe Co., 90–92 West Broadway, New York. For ten years *Compressed Air* has been, and still is, the only publication devoted exclusively to compressed air in all its applications. With the May number the size of *Compressed Air* will be changed to 7 by 10, it will be printed on better paper, and in outward form will be on a par with the best printed magazines now published. Mr. W. L. Saunders, M. Am. Soc. C. E., will remain as editor-in-chief, W. R. Hulbert, M. E., will be managing editor, and P. F. Kobbe, Jr., business manager.

TO OUR READERS

IN face of the calamity that has befallen the community in which we live, our own loss seems small. Our records, our library, the note-books of the editors, the manuscript ready for the printer, and the whole of the plant in our composing room, all lie buried under the ruins of San Francisco. But, owing to the customary precaution observed by two of us, complete copies of the weekly subscription lists had been taken to Berkeley, so that we possess that necessary record. Fortunately, most of the members of our staff live at Berkeley, where the earthquake was less severe and where no conflagration followed in the wake of this terrifying occurrence. As the earthquake occurred at 5:15 A. M., and the fire in San Francisco prevented people on this side of the Bay from reaching their offices, most of us were spared the horror of scenes that sear the memory. We are fortunate, therefore, as compared to many of our fellow citizens. And for other reasons. Our plant has been demolished; but this journal is built on nothing so ephemeral as paper, and on nothing so cheap as machinery; it is based upon the support of many thousand readers and subscribers who are never less likely to withdraw their support than at a time of misfortune. The goodwill of the Mining and Scientific Press is locked up in no safe, confined to no printing room; it cannot be shaken by an earthquake or consumed by fire. And, gentlemen, our friends, there is another something that is not destructible by physical misfortune or financial adversity, and that is the spirit that gives life to the printed word.

T. A. RICKARD,
Editor.

Berkeley, April 20, 1906.

TO OUR ADVERTISERS

OUR old offices at 330 Market Street, being in the very center of the most damaged section of San Francisco, have been totally demolished. We have lost our entire mechanical plant, including cuts, half-tones, type and the issue of April 21, which had already been set up; but fortunately, our complete and most recent mailing list has been saved.

We have secured ample offices in the First National Bank Building at Berkeley, which is on the east side of the Bay of San Francisco and close to the terminus of the trans-continental railroads. Through the courtesy of The Standard Publishing Company, we are in possession of proper facilities for printing. The Miehle presses, which will do our work, are new and of the most improved type. We will only be handicapped (for a few issues) by scarcity of paper; the rush of work at the local photo-engraving houses will prevent the use of half-tones with our reading matter, but we have arrangements pending to have this work done at Sacramento, which city was not affected by the earthquake.

We would urge all of our advertisers whose places of business have suffered, to communicate with us at the earliest moment, as our issue of April 28th will afford the best medium for advising their clients the world over of any change of address.

EDGAR RICKARD,
Business Manager.

EDITORIAL.

ASSAYING is always with us; therefore any improvement is of importance. On another page Mr. William Magenau gives a description of one method for the assay of cyanide solutions, and he follows this with a summary of other methods suggested during recent years. Some of our readers should be able to supplement this information out of the store of their personal experience. Such practical details, dealing with daily work, are invaluable.

OUR esteemed contemporary in New York has just celebrated, in its issue of March 31, the fortieth anniversary of a useful career. We tender congratulations to *The Engineering and Mining Journal*, and, from our lofty seniority of six years, we wish it an indefinite prolongation of literary and business activity. Old associations and, more particularly, the memory of days when, under R. P. Rothwell, that periodical was the recognized organ of the mining profession, may provoke regret that it should have gone the way of trade journalism, nevertheless, on this auspicious occasion, we send greeting to our contemporary—or rather, junior—on the Atlantic seaboard.

ON the occasion of its El Paso meeting, the American Mining Congress passed a resolution emphasizing the value of water supplies in the desert and asking that the hydrographic branch of the United States Geological Survey lend its aid in the ascertainment and mapping of such sources of supply, and the procuring of information such as will safeguard the water necessary to prospectors and others who travel in the arid mineral tracts. This resolution has been acknowledged by the Director of the Survey in a courteous letter, in which he states that his department is preparing a report on the springs and other water resources of the deserts in southwestern Nevada. Other maps of the dry areas in California and Nevada are under way, and on these great care is being taken to indicate all springs, together with trails and such landmarks as are essential.

STEAM-SHOVELS have been used successfully for stripping the iron ore of the Mesabi range, Minnesota, and also in Michigan, and it is interesting to note the application of them to copper mining. At the Cactus mine, in Utah, controlled by Mr. Samuel Newhouse, the steam-shovel is turning over 300 to 400 tons per ten hours and Mr. Lafayette Hanchett, the manager, is said to find the work satisfactory. It is proposed to adopt this practice in excavating the superficial portion of the large orebodies at Ely, Nevada. At Mt. Morgan, in Queensland, the same machine is being used to handle a gold ore, as it is broken in large open-cuts on the side of a hill. Some of the best work of the kind is done at the Virginia mine of the Oliver Iron Mining Company, on the Mesabi range, where excavations are now 40 to 50 feet below the surface. There, the steam-shovel handles 3,500 tons per 10 hours, lifting three cubic yards per dipper. At the Cactus the rate of working is only three-quarters of a yard per shovelful, but as applied to copper ore the practice is, as yet, in its infancy. It is an interesting development of practice and seems applicable to deposits of disseminated copper in soft porphyry such as are found outcropping at several localities in Utah and Nevada.

IN his weekly letter, our Toronto correspondent will be found to refer to an interesting step to be taken by the Provincial Government of Ontario, it having been decided that the mineral rights on the timber tract south of Cobalt are to be exploited for the benefit of the people of the Province. Work will begin as soon as the removal of timber is effected, the date set being October 1, this year. As the tract covers 100 square miles, and at least three or four square miles of it exhibits outcrops of unusual richness, the mining operations to be undertaken by the Provincial authorities will be important. While this departure is an innovation on this continent, it is a simple method of solving a difficult problem. At one time it seemed a choice between throwing the tract open on a specified date to prospectors, with inevitable disorder and individual injustice, or of putting it up to the highest bidder, subdividing the ground into claims of reasonable size. Even this scheme would have been unfair as affording the capitalist a better chance than the prospector, and it would have required the investment of money without previous examination or testing of the mineral deposits. Both of these alternatives having been discarded, we hope the Ontario Government will be able, with the advice of the capable technical men in its employ, to exhibit model mining operations. The experiment will be watched with keen interest.

EDWARD NICHOLLS, a miner at Kalgoorlie, in Western Australia, has been awarded a medal for conspicuous gallantry. On April 18—a year ago—Nicholls with two other men, Bentley and King, was working in a stope in the Lake View Consols mine. They had charged a round of holes and lit the fuses, and were in the act of retiring for safety to the level below. Bentley had retreated only ten feet when one of the charges exploded. Nicholls was further away and partially sheltered from danger. All the lights, of course, had been put out by the explosion. Nicholls called to find out if anyone was hurt, and, hearing the groans of Bentley, he groped his way back to the top of the broken ore in the stope, a height of 40 feet. There he found Bentley, with a big stone on top of him. The other charges were due to go off within two minutes. He extricated his comrade and succeeded, at the peril of his own life, in getting him to the bottom of the stope, just before the other holes went off. This act will be appreciated by miners, who know just what chances were taken in the rescue. The British authorities have awarded Mr. Nicholls an Albert medal of the second class, and while we recognize the appropriateness of such a distinction in recognition of acts of heroism, for which gifts of money seem an improper reward, we smile at the effort, the technical reason for which is understood, to classify acts of undiluted heroism such as this. There may be deeds to which this is second class, but we doubt it. When intelligence and unselfishness are so perfectly combined in one act, there is nothing more splendid.

Block-Faulting in the Great Basin.

Fremont, the foremost explorer of the West, justly styled 'The Pathfinder,' was the first to recognize and name the Great Basin. It constitutes a vast geological province, covering all of Nevada, portions of Idaho, Utah, Southern California, Arizona and New Mexico and extending far into Mexico. The orographic features are described by Clarence King in the report on the 'Exploration of the Fortieth Parallel' and by Powell and Gilbert in the monographs of the United States Geological Survey. The Basin Range structure, prominently characteristic of that volcanic region, has been discussed at great length in its broader features; of the block-faulting incidental to its development, little has been written; indeed, the article by Mr. Walter P. Jenney, in our issue of January 27, may justly be regarded as the pioneer paper upon the subject. Block-faulting is especially interesting to the miner as preparing the way for ore deposition by furnishing channels for the ascending mineral solutions that form the so-called primary ores. The common classification of fault-displacements is one of form, based upon the direction of the throw, or upon the attitude of the fault, whether horizontal, vertical or inclined. A few types of fault-structure are classified genetically, the notable example being normal faults produced by gravity. In shear-zones the throw is distributed over a number of parallel fault-planes, which are grouped together and considered as a single fault, but with this exception, the disposition has been to treat each fault as a unit, and not to consider them collectively in groups or systems. Mr. Jenney, after discussing the conditions under which block-faulting has taken place, says that it "may be defined as a phase of igneous disturbance, giving rise to a system of faults with diverse displacement, which, according to the nature of the eruption which gave them birth, may be local, regional or zonal in its distribution."

Admitting that, in the volcanic region of the Great Basin, block-faulting is commonly associated with marked evidence of igneous action, does it invariably result either directly or indirectly, from some phase of vulcanism? In other words, cannot any abrupt dynamic action, of sufficient intensity, give rise to block-faulting? The contraction of the earth's crust due to progressive loss of internal heat, may be conceived to produce sudden fracturing and displacement in zones of structural weakness. The Basin Range structure has been compared, in the diverse positions of the displaced and up-tilted blocks, to the

piling of broken ice upon the shore. In the example mentioned, we have more or less vertical displacement of the ice-blocks, resulting from the lateral pressure upon the ice-sheets when driven by wind or current upon the beach. There is surely nothing resembling igneous action in this; then why may not the crust of the earth, moved by a vastly more powerful force, produce block-faulting in like manner by lateral pressure? Further, this form of displacement in all probability occurs occasionally in regions where, at least in the geological formations, exposed at the surface, igneous rocks are absent. In the south part of the Ozark uplift the deposits of zinc and lead ore are associated with fault-systems which in some degree resemble the zonal type of block-faulting seen in certain places in the Great Basin, for instance in the dome-shaped uplift in Ophir Cañon, in Utah, already cited by Mr. Jenney. The fault-belt in southern Illinois, extending through Kentucky, in which occur deposits of zinc ore associated with fluor-spar, is another example. Mr. George H. Ashley, at a recent meeting of the Geological Society of Washington, described the occurrence of a number of zones of displacement, of this character, in the Appalachian region from Pennsylvania to Alabama. As Mr. Jenney says: "Now that attention is drawn to it, there is reason to anticipate that block-faulting will be recognized in volcanic regions in other parts of the world." But may it not occur, at least in occasional instances in regions which are not classed as volcanic? Although we may be compelled to admit the possibility, that a molten magma forced into the depths of the crust, of which nothing appears at the surface, may have caused the upheaval? If such should prove to be the fact, the occurrence of a zone of block-faulting in sedimentary formations would imply the existence in depth of intrusive igneous masses. This is evidently the view taken by Mr. Israel C. Russell, with respect to "subtuberant mountain uplifts."

The matter is of direct interest to the mining engineer as explaining the system of displacing fractures that interrupt exploratory work underground and also as suggesting the channels along which mineralization may occur. In the Ontario and Daly-West mines there is a striking illustration of the manner in which a rich lode was formed in one case along the plane of a big fault, and in the other along a flat layer of brittle rock lying immediately under a yielding stratum, the conjunction leading to the formation of a crushed zone, affording opportunity for solution of limestone and its replacement by ore. Both the 'vein' and the 'contact' orebodies owe their origin to the conditions created by block-faulting. It is a comprehensive idea which occasionally will be found to harmonize the particular set of fractures encountered in a mine with the generalized structure of its enclosing country, explaining the part in terms of the whole.

Smelters and Their Fume.

The time has come to call a halt on the persistent blackmailing of the smelters, under the assumption that they are a public nuisance. A proverb says that one man's bread is another man's poison; certainly, the operations which insure bread to many people may entail the poisoning of an occasional cow. We frankly state our willingness to see one or two cows, a few tons of hay, or many acres of pasturage injured by smelter fume, if that fume is the outward and visible sign of a beneficent industry. There is scarcely any operation of man that some one does not consider detrimental to himself; even the unselfish activity of a missionary may spoil the trade of a wine merchant and the zeal of a railroad builder may interfere with the revenue of a steamboat company. And in this clash of conflicting interest, it has become the unwritten law to decide opposing claims by their relation to the community, the greatest good to the greatest number being the axiom of custom and legislation among civilized people. In some localities the wine merchant is considered more useful than the missionary, in others the seller of stimulants is anathema; there are communities that prefer the steamboat to the railway, choosing low freights and slow travel rather than expensive, though rapid, transport. The farmers near Benicia and the ranchmen of the Salt Lake valley may look upon metallurgy as a diabolical art, but in mining districts anxious to market ore that is unsuitable for simple treatment on the spot, the smelter is regarded as a friend in need, and we mining people have learned to consider smelting as an altogether useful process that helps us to make money from mineral deposits. It is true that a certain big group of smelter people are now synonymous with rapidly acquired wealth, and this renders them less liable to sympathy than to criticism, some of which they may merit, but we are trying to discuss the matter now in a broad way as a contest between a useful industry that has helped to build up the country and an insignificant minority in the community who attack it and hamper it, prompted by motives that are plainly not altruistic. It comes to this, shall the mining industry which has made the West and today is still the great pioneer of commerce—shall mining be handicapped because a few people find it easy to extract money from smelters under guise of damage done to their property by fume? As a matter of policy, the managers of smelting works have always been willing to pay just claims and even to buy farms or lands said to be injured by sulphurous or other smoke, but the law is complicated and its technicalities favor blackmail. The law must be obeyed, we propose no such thing as the flouting of it; but the interpretation of laws is modified by the public opinion of the time and it is our hope to help the formation of a juster conception of the relation of the smelter to the community. Shall a few cows or horses, a ranch, or a hundred acres of deforested granite—shall these suffice to hinder a useful industrial operation that contributes to the wellbeing of many thousand persons? Take an illustration: A car line is projected along a certain street, to the intense annoyance of a few householders whose sleep or country quiet is broken thereby; are their protests considered sufficient reason for the abandonment of a convenient method of transport? Of course, it is regretted that anyone should suffer and the route is chosen so as to give minimum annoyance, yet it would never occur to a town council to veto a necessary car service because Jones or Smith objects. If the street on which they live is not chosen, then Brown and Thompson, on the other street, will raise a rumpus because they suffer discomfort. Or take another case; railroads spoil the scenery of a country and disfigure the streets of a city; the proximity of noisy traffic is injurious to some of the best forms of real-estate investment; yet no one would listen to the small minority who suffered from this cause; public policy does not sanction the treatment of the railroad company as an unmitigated nuisance, nor does it encourage persistent damage suits. The community accepts the railroad as a convenience and each member of it is expected to put up with his share of annoyance or damage in order that the community as a whole may profit by better facilities of communication. The individual must give way to the general good. So also with a smelter; the site is usually chosen remote from the homes of the people and always to leeward of the prevailing winds. Occasionally this cannot be done; sometimes the smelter is in the town itself, as were the first works built at Leadville and Omaha; sometimes the site is outside the city, but the latter grows until the smelter is well within the settlement, as has happened to the Argo and the Grant smelters, at Denver; more rarely, a town is frankly given up to mining, so that the hurt to vegetation is not considered at all and the rising smelter smoke is regarded as a sign of prosperity; as was formerly the case at Butte City. For mining communities that have been built up by the aid of smelting and for towns that were made by their reduction works, and that now try to hold up these metallurgical establishments, we have no sympathy whatever. Many years ago some of the people of Swansea, in Wales, importuned Parliament to put a restraining hand on the chemical and smelting works whose sulphurous fume was destroying the vegetation, and they received the retort that they were killing the very industry that made them: What would Swansea have been save for her smelters? So, too, in regard to Butte City, Salt Lake City, Denver and even San Francisco, we ask: What would these cities have been save for the mining industry which built them up, and sustained them until, in some instances, there gathered a population that could buy the produce of the farm and field? The mine and the smelter created the market for their produce.

By the Way.

Writing for the *Athenæum* on helium and the transmutation of elements, Prof. William Ramsay says that the story of helium is perhaps the most romantic in the history of science, and a story of which the last chapters are still unwritten. Originally seen as a spectrum line in the chromosphere of the sun, it was discovered on the earth, 28 years later; and has provided the first authentic case of transmutation—a problem which occupied the alchemists from the sixth century. Prof. Ramsay tells of the discovery in 1868 of the spectrum of helium, and then continues:

"Shortly after the discovery of argon in 1884, the notice of one of the discoverers was drawn to an account by Dr. Hillebrand, of the United States Geological Survey, of the presence in certain ores containing uranium of a gas which could be extracted by an air-pump. Hillebrand examined the spectrum of the gas, and supposed it to be nitrogen. It is true that he saw in it spectrum lines which could hardly be ascribed to nitrogen; but on mentioning the fact to his colleagues, he was bantered out of his quest, and did not follow up the clue. Now in the spring of 1895 attempts were being made to cause argon to combine; and it was argued that conceivably Hillebrand's gas might turn out to be argon, and might give an indication to a possible compound. Consequently, a specimen of clevite—one of the minerals which Hillebrand had found to give off the supposed nitrogen in largest quantity—was purchased, and the gas was collected from it. On purification its spectrum showed the presence of a brilliant yellow line, almost identical in position with the yellow lines of sodium. It was soon evident that the solar gas, helium, had been discovered on the earth.

"The minerals which contain helium have one thing in common; they all contain uranium or thorium, or lead, or a mixture of these. Minerals of lead alone do not show the presence of helium; but it may be stated that helium is an invariable constituent of ores of uranium and thorium. It was at first supposed that such minerals contain helium in a state of combination; but this view could not be substantiated, for the constituents of these ores do not show any tendency toward combination with helium. The connection of this with what follows is very remarkable.

"The explanation of the fact that compounds of radium discovered by Madame Curie in 1901 are permanently at a temperature considerably above that of the atmosphere and that they are continually emitting corpuscles of high velocity, was given by Prof. Rutherford and Mr. Frederick Soddy in a series of papers communicated to the *Philosophical Magazine*. It is that radium and allied bodies are 'disintegrating'—that their atoms are spontaneously flying to bits. Now this view, although new in its application to elements, has long been known to hold for certain compounds. There is a fearfully explosive compound of nitrogen with chlorine which on the least touch resolves itself suddenly into its constituent elements. It is true that here we have a molecule composed of atoms disintegrating into atoms which subsequently combine to form new molecules of nitrogen and of chlorine; but in principle an analogy may be drawn between the disruption of the molecules of an explosive compound and the disintegration of an atom into corpuscles. Prof. Rutherford and Mr. Soddy showed, however, that corpuscles which have been proved by Prof. J. J. Thomson of Cambridge to be exceedingly minute are not the only products of disintegration of the radium atom; the proof was adduced that among these products were atoms of a density comparable with that of hydrogen and helium. This hypothesis evidently admitted of experimental proof, and in conjunction with Mr. Soddy I collected the 'emanation' or gas evolved from salts of radium. We showed that this gas, presumably of high density, disintegrates in its turn, and that perhaps seven per cent of it changes into helium. What becomes of the remaining 93% is as yet undecided; still some hint may be gained from the fact that a constant ratio exists between the amount of helium obtainable from a mineral and the weight of lead which it contains. It may be that lead forms the ultimate product, or, at least, one of the ultimate products of the disintegration of the atom of emanation. Another radio-active element, actinium, has been shown by its discoverer, Debierne, also to yield helium by the disintegration of the emanation, or gas, which it continuously evolves. This disruptive change is attended by a great evolution of heat; for the radio-active elements are in a sense explosive; and explosions are always accompanied by a rise of temperature. But such atomic explosions surpass in degree, to an almost inconceivable extent, the molecular explosions with which we are familiar. Could we induce a fragment of radium to evolve all its energy at once, the result would be terrific, for in the energy with which it parts during its change it surpasses in explosive power our most potent gun cotton by millions of times. It has been suggested that to this or similar changes are due the continued high temperature of the sun and the presence of helium in its chromosphere."

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and to give information dealing with the practice of mining, milling and smelting.

SOME assayers prefer to use tacks rather than nails in making assays of sulphides.

THE melting point of tin is 446° F. That of gold 2,097° and of platinum 3,227°.

LITTLE mica is produced on the Pacific Coast and the market for the mineral is limited.

ORDINARILY 100 tons of waste broken in the mine will fill the space previously occupied by 150 tons of ore.

A JAW ROCK-BREAKER, 10 by 16 in., requires about 15 h.p. more or less, depending on the hardness of the ore.

MEXICO produces a variety of rare combinations of silver, copper and lead—minerals almost unknown elsewhere.

DYNAMITE is the name applied to all kinds of nitroglycerine blasting material when mixed with an absorbent.

THE addition of barium peroxide to a cyanide solution will materially hasten the dissolving of gold placed in solution.

AN explosive compound may be made by immersing ter-chloride of gold in caustic ammonia. It is an unstable and dangerous compound.

THERE are large areas of serpentine in California and asbestos occurs in many places in it, but rarely in large amount or of commercial value.

THE sulphide of tin occurs in nature as the mineral stannite, but is comparatively rare. It also is found combined with copper, sulphur and arsenic.

WINDING at some of the deep shafts on Lake Superior, at Butte and in California is at the rate of 3,000 to 5,000 ft. per minute, when at maximum speed.

SULPHURIC ACID may be concentrated by boiling, and so long as the temperature does not rise above 300° F. little or no sulphurous fumes pass off into the atmosphere.

ELBOWS, sharp bends and other irregularities in pipe-lines increase the friction of the currents of air or water passing along the line, and should be avoided as far as possible.

IF a solution is saturated while warm and then allowed to cool, frequently the mineral in solution will crystallize. This fact is often taken advantage of to obtain crystals of various substances.

THERE are now recognized 75 elementary substances. The lowest atomic weight is that of hydrogen, 1.008; the highest uranium, 238.5. That of gold is 197.2, and of platinum 194.8. Radium is placed at 225.

OLD nitro powder is extremely dangerous. It may not be as effective a blasting agent as new powder, but it still possesses terrific explosive force and should be handled with as much caution as new powder.

HIGH-GRADE POWDERS generally shatter the rocks in small fragments, the lower grades breaking the rocks larger. Accordingly the miner and quarryman chooses the powder best suited to his requirements.

METHANE is a simple compound of hydrogen and carbon, and next to hydrogen is the lightest gas known. It is highly inflammable, and is known also as marsh gas, from its occurrence in marshes, due to the decomposition of organic matter.

MINERAL COLLECTIONS are of little value unless properly classified. Museums containing many thousands of specimens must necessarily have many duplicates from various localities, as there are only a few hundred species recognized.

CHARCOAL will precipitate gold from chlorine and cyanide solutions. It has been extensively used for this purpose in the chlorination process as practiced at Mount Morgan, Queensland, Australia, but is almost unknown in practice elsewhere.

GOLD is sometimes found in placer sluices, coated with mercury, and is mistaken for platinum. Heating the gold will cause the mercury to be volatilized, leaving the gold bright yellow. The mercury can also be removed by placing the metal in nitric acid.

A CROSSHEAD for use in a shaft to prevent swinging of the buckets, should be at least twice as high as it is wide to lessen as far as possible any tendency of the crosshead to jam in the shaft, something that not infrequently happens when the crosshead is short.

ONE of the deepest soundings thus far recorded is that made by H. M. S. *Penguin*, which reported a depth of 4,762 fathoms—more than five miles. This sounding was taken between Auckland and the Tonga archipelago (Society Islands), in the South Pacific Ocean.

A SHORT CIRCUIT is the term used in electricity to indicate that a connection between a positive and negative wire has accidentally been made, enabling the current to take a short cut, instead of completing the current through the wires, and lamp or motor.

WHEN asking questions of 'Concentrates,' state the proposition clearly in order that the question may receive an intelligible answer. Often questions are asked in which insufficient data are given, and this renders the matter of suitable reply either difficult or impossible.

WHEN saltpeter is strongly heated it gives off a gas. When the evolution of the gas ceases a crystalline substance remains which, upon treatment with sulphuric acid, yields red fumes, something which saltpeter will not do. Saltpeter can be further decomposed by heating.

FOR many centuries water was regarded as an element, until in 1781, Cavendish discovered that when a mixture of hydrogen and oxygen exploded water was formed. Later it was realized that water was composed of two elements — hydrogen two parts and oxygen one part.

MEN shoveling in a close drift are not infrequently given the racking, nauseating headache, known as powder-head, hours after blasting, from the fumes of nitrous oxide imprisoned in the wet muck, which is released into the air of the drift by the shoveling of the workmen.

THE mine owner must so operate his property that no damage is done to his neighbors. He may do things in what he may consider a workmanlike manner, and still damage may result, for which he is responsible. His contention that he worked in a workmanlike manner constitutes no defense.

OXYGEN is apparently essential to the dissolution of gold in cyanide solutions. It is said that if gold leaf be dropped into a solution of potassium cyanide contained in a bottle, and tightly corked, the cyanide will have little or no effect on the gold, but if the cork be removed the gold will soon disappear.

THE richest copper ore is cuprite, which, when pure, contains 88.8% metallic copper. There is no chalcocite (copper glance) containing 82% copper, for this mineral, when pure, contains only 79.8% copper, and 20.2% sulphur. It is not uncommon to find the metallic content of high-grade ore overstated.

A MILL-RUN would have little value unless careful checks were made on all that takes place during the run. Among these things are: Amount of ore treated during the run; amount of gold and silver saved by amalgamation; percentage of concentrate saved; value of concentrate per ton; assay of tailing, and subsequent extraction of cyanide.

ANY citizen of the United States (including women and minors) may legally locate a mining claim on the unoccupied lands of the United States, provided a *bona fide* discovery can be made. A person, an employee of a company, having no fiduciary or confidential relations of trust with a company, may locate a claim for himself or for others in the hours when he is not on duty.

IF the crosscut passed through the vein and encountered a dike, and a drift on the vein soon ran out of ore, it may be possible that the vein was intersected by the dike. The crosscut should be continued through the dike and a drift run on the opposite side to ascertain whether the theory advanced is correct. The description of conditions warrants a belief in the opinion above given.

PAYSTREAK, in the parlance of the placer miner, means that portion of the channel or deposit containing the highest values, even though the poorest portion be payable. To the vein miner it represents the best portion of the vein. In many veins there is a streak at one side or the other, or in the center of the vein, carrying high-grade ore—the paystreak—whether the balance of the vein can be profitably handled or not.

ROCKS are mineral aggregates. They are either simple, as calcite (calcium carbonate), siderite (iron carbonate), or gypsum (calcium sulphate); or composite, as diorite, diabase, granite, etc., each of which is made up of several separate minerals. The names applied to rocks usually indicate their character, as quartz-mica-diorite, which means a diorite in which quartz and mica occur, neither of which are essential to diorite.

EPIDOTE is a mineral of peculiar yellowish-green color, the result of alteration usually of hornblende or augite. The augite alters to the variety of hornblende known as uralite, and this or original hornblende is changed to chlorite and the latter by further alteration to epidote. It is a common constituent of metamorphic rocks containing hornblende, and also in diorite and granite. Its presence has no valuable significance.

DIABASE has so frequently been found associated with gold-bearing veins that many have come to look upon that rock as a safe indication of a valuable gold mine. This is a fallacy, for diabase is found in scores of places where no gold is known. Andesite and granite are as much entitled to be considered as indicative of profitable gold mines as diabase, if not more so; but andesite and granite, like diabase, occur over hundreds of miles of territory with no sign of gold.

THE 'law of multiple proportions' is to the effect that when two elements combine to form more than one compound, the different weights of the one element which unite with one and the same weight of the other element bear a simple ratio to each other. The absolute weight of atoms is not known. They are so small that no one has ever undertaken or, at least, succeeded in determining either the size or weight of atoms, or of molecules, except approximately.

ARSENICAL SULPHIDES are not always rich in gold, though in regions of gold ores the mispickel is usually gold-bearing, as galena is usually argentiferous, though in some regions the amount of silver present is very small, as in the lead-zinc ores of Missouri. In California arsenical sulphides are frequently found associated with pockets of gold, and therefore the appearance of mispickel has come to be considered as an indication of the proximity of a gold pocket in some mines.

IT would be a difficult matter to pre-determine the life of a steel cable on a gravity tram without knowing anything about the conditions under which the rope would work. The length and grade of the tramway are important factors; also the presence or absence of idlers to carry the rope. Curves are also important if there are any. A good rope, if kept in good condition by the use of rope grease, should last as long as a similar rope in an inclined shaft of the same degree of inclination underground.

THERE are few lead minerals having a large commercial value, owing to their comparative scarcity. The principal sources of the lead of commerce are galena and carbonate of lead. The lead minerals, however, form many of the most beautiful specimens and are highly prized by collectors of minerals. Among the most attractive of the lead ores are: wulfenite (honey yellow), vanadinite (orange red), cerussite (the white crystallized variety), anglesite, pyromorphite, and linarite, the latter a beautiful blue mineral, being a sulphate of lead and copper.

HYDROGEN is produced from several of its various compounds; water is decomposed by the electric current, and hydrogen is set free; palladium-hydrogen is broken up by heat and hydrogen and palladium freed. The ordinary methods of obtaining hydrogen are some of the following: The action of dilute sulphuric acid on zinc; the action of zinc or aluminum filings on caustic potash or slaked lime; the action of sodium or potassium on water or alcohol; magnesium powder, when boiled with water, evolves hydrogen, particularly when some magnesium chloride is dissolved in the water, for the reason that such a solution dissolves the magnesium oxide which forms on the surface of the metal. Red-hot iron immersed in water causes a decomposition of a portion of the water with the liberation of hydrogen.

ONE method of making copper sulphate is the following: Copper is immersed in sulphuric acid, 66° B., and the acid heated. The acid is partly decomposed; the copper is transformed, first to sulphide and then to oxide, sulphurous acid and steam being liberated. The undecomposed sulphuric acid unites with the oxide of copper and transforms it into sulphate. By continuing the heating operation, the excess of sulphuric acid, if any, volatilizes, and anhydrous sulphate, mixed with a small quantity of sulphide of copper, remains. On again treating the mass with hot water, the sulphate dissolves; the liquor is decanted and crystallizes on cooling. The copper remaining still unattacked, if any such exists, is collected and again enters the cycle of operations. The copper is introduced metallic, either granulated, precipitated or as sheets or wire.

SULPHIDES are usually sampled in the sacking room, by taking a quantity from the sacked concentrate by means of a half-round instrument of Russia iron similar to a butter-tryer. The tryer can be pushed down into the sulphides as far as desired, and they usually contain sufficient moisture to enable the assayer to obtain an average sample of the contents of the sack. Samples may be taken in the same manner from the pile of sulphides on the floor, or from the vanner boxes, if not too wet. The samples thus taken may be dried and assayed separately, or they may be mixed and an average taken, which should give results approximating those obtained by a mechanical sampling works, from the same material, if the sample is taken in proper amount from each place. It would be manifestly improper to take a two-ounce sample from a sack containing 120 lb. of concentrate and to take the same amount from a sack containing only 80 lb. If the sulphide is fairly even in value no great discrepancy will result; but if one be much higher grade than the other, the mixing of samples will not give correct results. At the reduction works the sulphurets received for treatment are usually sampled automatically by machinery, which will give as accurate results as can be obtained by hand manipulation.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

HANDLING MEN.

The Editor:

Sir—I was very much interested in the article written by R. B. Nickerson, which appeared in your issue of March 3, headed 'Handling Men Underground,' and while I am willing to admit that the article is well written and shows the result of some observation of men and things, yet it strikes me as being somewhat over-drawn, in that the type of foreman first described would seem to be entirely destitute of all vestige of humanity, while the second is almost too much of a good fellow.

In my experience of more than sixteen years, in and around mines, acting in every capacity from mucker to superintendent, I have come in contact with a great variety of mine-foremen, some of them in many respects resembling the type first described by Mr. Nickerson and others who approximated the second, but I have, as yet, failed to see men of either type who were eminently successful, in every sense of the word, in the knotty problem of handling men.

The first type is, if I may be allowed the term, a 'bull-dozer' and is only fit to drive cattle, and indeed hardly that. A man (save the mark) who is so utterly devoid of all sense of right and justice as to be continually harassing the men under him, sneaking in on them at all unlikely moments, trusting no one and refusing to be satisfied when his men have done a good shift's work, is the kind of creature who kicks at the head of the man below him in position and cravenly licks the heels of the person above. He is the most contemptible creature on the face of the earth and, it seems to me, no one, whether miner or superintendent, could have a particle of respect for such a cur. I have in mind at this time a fellow who was given a little brief authority in the Black Hills in the year 1890. He did not shine as a miner to any great extent and whenever the chance presented itself would 'throw off' and was an adept at extinguishing his light and "watching the boss" from the shady side of a post or other coign of vantage. For some inscrutable reason (probably on the theory that it takes a thief to catch a thief), he was elevated to the dignified position of shift-boss in the Homestake mine. With this unlooked-for dignity thrust upon him, he commenced tyrannizing the men under him, many of whom were his superiors in every way, and acting out the part of Mr. Nickerson's party of the first part very closely indeed. He managed to hold this position for 8 or 10 months and was then relegated to the hammer again, his superior officer evidently recognizing the fact that the actions of such an intolerant, inconsistent ignoramus did not make for 'results' in the long run.

Now for Mr. Nickerson's other character. A man who has acquired a reputation among his employees as 'a good man to work for' and 'a fine fellow' etc. without qualification, may generally be regarded with some suspicion by his superintendent and it is likely to be found before long that "there is a nigger in the woodpile" somewhere. A man in charge of the underground work of a mine has all kinds and characters of men to deal with and he will be compelled to treat every one according as he finds him. He will find it impossible, as long as he is human, and only human, himself, to be "quiet, genial, courteous, and pleasant in all his dealings with his men"—to quote Mr. Nickerson—because he will be sure to get his share of that shiftless, careless 'ten-day' brand who will tax the spirit of a saint. He may be situated in some remote place, where the kind of workmen he would naturally select are not available and he will, therefore, be compelled to handle many who are incompetent and, in many ways, undesirable. Then, too, no man's judgment is infallible in sizing up another man's worth at first sight and he will, therefore, find those undesirable, shirking ones creeping in among his force and, if that force be a large one, it takes some little time to weed them out and get others in their places. If he tries, as Mr. Nickerson says, to make a good workman out of inferior material, this proceeding will take time also and, in many cases, will result in disappointment.

It has been said, and perhaps with some degree of justification, that the mine-foreman is situated between the devil and the deep sea. On one side, the management is looking for and demanding results, and on the other a disgruntled, incompetent, careless, shirking crew is by all means to be avoided. The man most likely to fill this gap and handle these conditions successfully is he who represents the happy mean between the 'bull-dozer' and the 'good fellow.' He must be able to judge human nature as well as possible; he must be competent to pass on a man's merits as a worker and know whether or not he is doing a day's work, without sneaking in on him; he must have a reasonable disposition, not railing at a man and finding fault with him and his work without just cause for doing so. There is nothing that will make a man so sore as to be brow-beaten and found fault with when he has conscientiously done his best.

I am firmly of the opinion that hard and fast lines cannot govern the personal relations between a foreman and his men. Different men require different treatment; there are those who, if bull-dozed, will pretend to take it and swallow it and then seize every opportunity to "get the best of the pusher;" in another case, such a proceeding would simply precipitate a quarrel or, possibly, a ridiculous scrap. Then there is the suave, smart kind who has the habit of saying Yes and No just as the boss appears to wish, and who gets the idea sometimes that he is "all solid." This brand must be given to understand that they must get in and drill, or it will be all off with them in a hurry.

As to a foreman conferring with his men: There are lots of men with whom a foreman can confer to good advantage indeed, while there are many others from whom it would be simply ridiculous to ask an opinion. In regard to married men: All other things being equal, a married man is to be preferred to the single for the reason that, as a rule, he cannot afford to be arrogant or shirk his duty or engage in needless discussions and criticisms; having the responsibility of a family he is more disposed to be reasonable and to do the right thing by his employer than the irresponsible single man whose home is the bunk-house and whose entire belongings can be rolled up in his blankets at a minute's notice, to hit the trail for "greener fields far away." This, however, on the premise, stated above, that all other things are equal. I have had single men work for me month after month, doing good work and giving entire satisfaction; they have ultimately left and I knew I had lost good men; I have had married men on my force who, to judge by their actions, seemed to think they had a right to be cared for and kept on simply because they were married.

As I intimated before, the mine-foreman's lot is not an entirely enviable one; his business is exacting; his experiences manifold; he is compelled to govern his actions in accordance with circumstances and he will find that, do what he may, his actions will be continually criticised by his employees, but the nearer he comes to the standard of treating his men right, demanding full day's work and giving credit for the same, asserting his will when he knows he is right, and refusing to bully on the one hand or toadying or being toadied to on the other, the nearer, in my humble opinion, he will come to being successful in all that the term implies, for in this, as in every other walk of life, success can never be attained at the expense of character, integrity and manhood.

EDWARD W. RALPH.

Seattle, Washington, March 9, 1906.

THE BEST SHAPE FOR A SHAFT.

The Editor:

Sir—This is rather a large subject to be adequately treated in the limited space which you can allot to such discussion, and the statement of individual views and opinions in your paper. The best shape for a shaft depends very largely on—and ought to be determined for—the special conditions of each case. I shall, therefore, in my remarks, mainly follow the conditions of the case mentioned in Mr. Burrows' statement.

In deciding on the shape, or horizontal section, of a shaft, we ought to take into account:

1. The amount of rock and water which it is intended to hoist regularly through the shaft from a stated maximum depth, allowing for a possible large excess of water over and above the anticipated amount.

2. The facilitating, and thereby expediting, of sinking, that is, the influence of any particular shape on blasting, and on hoisting the broken rock, 'mucking,' and last, but by no means least, for taking care of any unexpected quantities of water which may be encountered in deepening the opening at any time.

In other words, in deciding on any particular shape for the shaft, it will be advisable to consider, in the first place, what I may call the ultimate maximum duty, which the shaft may be called on to perform in the way of hoisting rock, water, men, tools, etc., and in the second place, if two different shapes would serve this purpose equally well, or approximately so, to give that shape the preference, that will give the best facilities for the work of sinking. And in this last consideration it is the facility and convenience of handling the water, which is of far greater importance than the possible saving of 15 or 20% of 'mucking.' Any blast may bring a sudden and unexpected influx of water.

To come to the case under consideration: The old Mexican shaft 320 ft. deep, with a square section of 10 by 10 ft. This shaft is to be sunk for the present 2,300 ft. deep, with the probability of it ultimately reaching a depth of 4,000 to 4,500 ft. This last feature of the case is not stated by Mr. Burrows, but it was one of the reasons why the possible enlargement of the 10 by 10-ft. shaft to a 10 by 16-ft. shaft was taken into consideration, if it ever should become necessary to have greater hoisting capacity than the 10 by 10-ft. shaft would afford. We may, therefore, leave the 10 by 16-ft. shaft out of our discussion and confine ourselves to a comparison of the 10 by 10-ft. square shaft with the 5 by 16-ft. oblong shaft, with and without the 'jog' at 300 feet.

It seems to me that the question whether the 10 by 10-ft. shaft with its nominal 100 sq. ft. will require 25% more mucking than the 5 by 16-ft. shaft with its nominal 80 sq. ft. area, and will, therefore, be slower in sinking, cannot be affirmed. The 10 by 10-ft. section will allow deeper drill-holes, heavier charges, and thereby require a smaller number of removals, and re-installment of drills and pumps. There will be less shattering of the sides of the shaft by blasting in a length of 10 ft. than in 16 ft. How much this difference in favor of the 10 by 10-ft. shaft will amount to, depends altogether on the nature of the rock and the skill of the mine foreman; it cannot be foretold. My opinion is that even in such firm, well-standing rock as will probably be encountered in the Guanajuato shaft, not over 15% additional 'mucking' will have to be charged against the 10 by 10-ft. as compared with the 5 by 16-ft. shaft.

The alleged inconvenience of timbering a 10 by 10-ft. shaft as compared with a 5 by 16-ft. shaft, need hardly be considered seriously. The increase in the size of one of the timbers for the 10 by 10-ft. shaft and the thereby increased cost amounts, when figured out, to such a small matter that it will be probably more than balanced by the decrease in the cost of putting in three vertical rows of timbers, two ends and a divider, as against four vertical sets, two ends and two dividers. At any rate the difference in the cost of timbering the two shafts will be too small to be a factor in the choice.

The main reason for Mr. Burrows' (and many other good engineers') choice of the oblong three-compartment 5 by 16-ft. shaft, has evidently been the compelling force of custom. It is done that way anywhere, "In South Africa, California, and other mining regions," and therefore it must be the best way to do it in this case. Follow in the old rut. It is eminently safe. Unfortunately for the case in hand, a jog in a shaft, 320 ft. below its collar, is not customary; and that circumstance set some of the directors to thinking, whether an oblong 5 by 16, or 6 by 16-ft. shaft was in reality preferable to a 10 by 10-ft. shaft, and if so, whether the advantages of a 6 by 16-ft. shaft over a 10 by 10-ft. shaft were sufficient to justify changing the size and shape of the shaft, already sunk as a 10 by 10-ft. shaft to a depth of over 300 feet.

By changing the 10 by 10-ft. shaft, at 320 ft, to a 5 by 16-ft. shaft, we evidently are able to use only a 5 by 10-ft. space for hoisting purposes. All hoisting, whether rock-buckets or water-tanks, pumps, pipes, men, tools, timber, etc., will have to be done through the two compartments in the 5 by 10-ft. space. We may install a sinking, or permanent pump, in the 5 by 6-ft. space underneath the jog; but to lower the pump after blasting, and to hoist it out of the way of blasts, we will have to swing it into one of the 5 by 6-ft. spaces underneath the jog. That a sinking pump can be much easier and more quickly handled by an extra hoist and separate cable in the 10 by 10-ft. shaft, is too obvious an advantage and too self-evident, to need any further elucidation.

There is at least as much hoisting area for rock in the 10 by 10 as in the 5 by 16-ft. shaft. Beside, there will be in the 10 by 10-ft. shaft an additional hoisting area of 4½ by 10 ft., which by means of a separate hoist may be utilized for hoisting-pumps, water-tanks, tools, timbers, etc., without interference with the hoisting of broken rock. The square shape of the shaft, with the long 4½ by 10-ft. compartment behind the twisting compartments, makes for greater accessibility of any compartment for repairs and in case of accident. If two hoisting compartments put into the 5 by 10-ft. hoisting area of the 5 by 16-ft. shaft, are sufficient to hoist 1,000 tons from 4,000 ft. depth, the same area is available in the 10 by 10-ft. shaft, and more, if necessary. We might make the hoisting-area for rock 6 by 10 ft. and still have plenty of room for pump-compartment, ladder-way and timber-skip. If it was not for the jog at 320 ft., we should have, in the 5 by 16-ft. shaft, a 5 by 5-ft. compartment coming to the surface through which hoisting might be done, but hardly with convenience or safety, if this 5 by 5-ft. compartment were also to accommodate water and air-pipes, electric wiring, beside a possibly necessary ladder-way. The 4½ by 10-ft. space of the 10 by 10-ft. shaft will allow putting all this at one end, leaving plenty of room for hoisting at the other end. The advantage in sinking of having 10 by 10-ft. hoisting space, as against 5 by 10, and thus being able to use double the number of buckets or water-tanks, by simply installing an additional small hoisting-engine, is so obvious—I need not further enlarge on it.

There remains, in favor of the oblong usual three-compartment shaft only the sanction of old custom. Without any special justification, this custom has gradually established itself by the growth of the original one-compartment shaft to a two-compartment shaft, in which one cage balanced the other, the drums being placed on the same shaft of the winding-engine. When later a third, fourth, fifth or sixth compartment became desirable, it was only natural to lengthen the shaft. The shape of the shaft was adapted more to the type of winding-engine used and to the convenient position of these engines; more so, at any rate, than the construction and position of this machinery to the best possible shape of the shaft.

As stated in the beginning of this communication, the best possible shape, or horizontal section, for any

shaft ought to be determined by all the conditions surrounding each individual case. It may be the present, usual, oblong, rectangular shape. It may be a square shaft, as in the case under review. It may be a round or an elliptical shaft. It may even be an octagonal shaft like the celebrated Valenciana and Rayas shafts at Guanajuato. It all depends on the conditions of each special case. The hoisting machinery can be constructed, and certainly can be placed to suit the requirements of any possible best shaft-section. The shape, especially of a costly deep shaft, should certainly not be made dependent on any preconceived notion of placing the hoisting machinery.

CARL HENRICH.

Metasville, Georgia, March 22, 1906.

THE BEST SHAPE FOR A SHAFT.

The Editor:

Sir—There can be little advantage to the profession at large if the discussion as to the best shape for a shaft is to be fixed by the conditions advanced by Mr. Burrows, wherein he describes a particular shaft of unusual proportions that is already partly constructed, and which so far fulfils the requirements of the occasion that the management has decided to avail itself of the old opening for the development and operation of the property. In its application to this particular shaft, the discussion should bear more generally upon the best shape for *all* vertical shafts, whether the same be circular, elliptical, polygonal single or double-width rectangular-cross-sectional areas. If the various conditions under which the different shapes are best suited to a particular class of work can be established by such a discussion, much good will be done, while if those which affect the shaft itself during its construction and the causes which make one shape the best at one point or mine and another shape or construction more suitable at some other point are clearly pointed out, the profession will also be the gainer.

Circular shafts are but little employed in America, but they are much used in Europe, and in the Witwatersrand goldfields of South Africa; on the Rand one of 11-ft. diam. in the clear has been sunk at the New Primrose mine and one 15-ft. diam. at the Langlaagate Royal. Such shafts are constructed of stone, brick or cement walling, of metal cast to required shapes in the form of tubbing, or by assembling together segments formed of structural shapes bent to required curves to form the supporting structure. Such shafts are particularly well adapted to firm ground, but they may be employed advantageously under all conditions, except where the structure is subjected to unequal and uneven pressure or where there is a creep of a portion of the enclosing rock-masses with reference to other portions thereof. On account of their shape, much space is rendered unavailable to the uses of the mine, except so far as such unused space is advantageous to the ventilation of workings. The compartments are separated from each other by dividers built into the walls or attached thereto, to which are affixed the guides upon which run the skips or cages and from which are hung the water-columns, air and steam-pipes, and ladders.

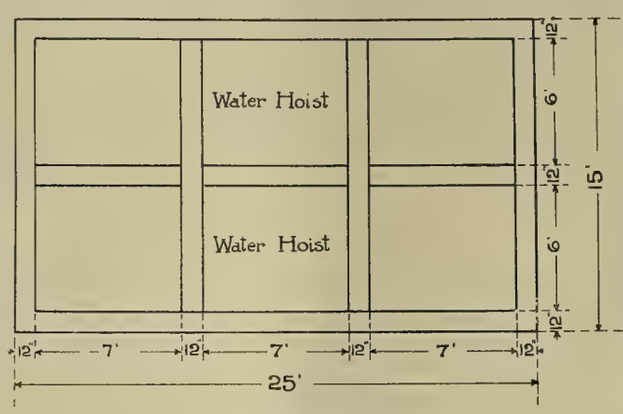
Elliptical shafts are sometimes employed in preference to the circular shaft, the advantages being that there is less waste space in one of such shape; and if they are properly placed with reference to unequal pressure from the walls, such a construction is considered to be superior in strength to the circular form. Other considerations apply equally to both forms.

Polygonal shafts are sometimes, though rarely, employed at the present time. At Guanajuato, in Mexico, where is situated the shaft described by Mr. Burrows, the hexagonal shaft of Nuestra Señora de Guadalupe has long been sunk, the octagonal main shaft of the Mellado, 40 ft. inside diam., had reached the depth of 1,260 ft. early in the last century, while the great octagonal shaft, El Tiro General, of the Valenciana mine, 36 ft. inside diam., had reached a depth of 1,700 ft. prior to 1820. The reason for this use of the octagonal shaft lies in the fact that eight separate whims, each operated by from 12 to 16 horses in shifts of three hours, were simultaneously employed upon the shaft in connection with the work of hoisting to surface the water and material extracted from the interior workings of the mine. The wall-rocks of these shafts were such that no artificial structure was required for their support; but under conditions where the enclosing ground must be held in position through artificial means, it is certain that the circular or rectangular form would in every way be stronger and better than could any possible polygonal construction.

Rectangular shafts are more generally applied to the various operations connected with underground mining than are other shapes, and probably for the reason that (except under abnormal conditions to overcome which the circular shaft is sometimes peculiarly adapted) the rectangular form can be so much more easily constructed and repaired and the parts of the supporting structure placed in position, aligned and fixed in place, and removed and replaced with comparatively little difficulty. Furthermore, when the rectangular shaft is designed with reference to the operations that are to be carried on through it, there is little waste space, the working is compact and all parts thereof are accessible and handily placed for the work in view and for inspection or repair.

Rectangular shafts are of three kinds — the L shaft, the single-width shaft and the double-width shaft. Under ordinary conditions the L shaft should never be employed, for its shape is such that it must necessarily increase the expense of breaking ground to the required form; where the enclosing rock possesses a tendency to swell or where movement is likely to occur, a twisting movement is set up within the frame and causes unequal pressure upon the parts. It is a question if it would not be more satisfactory and more economical to extend the shaft mentioned by Mr. Burrows as a double-width four-compartment shaft to the deep rather than attempt to eliminate waste space existing in the four compartments by the construction of a three-compartment L shaft within the limits of the original shaft.

The modern practice of balancing loads upon the hoisting engine makes for economy in operation, and therefore rectangular shafts are usually constructed with two hoisting compartments under conditions which warrant so large a shaft. A third compartment, therefore, is necessary for the accommodation of contrivances connected with the drainage, ventilation and power-appliances needful in underground mining, together with the handling of timber and other supplies. This compartment is therefore added to the shaft, at the side of the two hoisting compartments, making a three-compartment single-width shaft, and it is this reason probably which has brought the single-width construction into such general use. Another reason favoring its employment is that the single-width shaft lends itself more readily to enlargement at any and all times than does any other shape, while in the larger four, five and six-compartment shafts the construction is such that the supporting structure may be repaired and the parts thereof replaced in units without a complete cessation of operation, certain of the compartments being closed for repairs, while others are available for work.



Plan of Red Jacket Shaft.

Where large quantities of material are hoisted through a shaft, so that it becomes economy to give up two hoisting-compartments entirely to such use, and where considerable quantities of timber and other supplies are lowered into the mine, one or more compartments are added to the three-compartment shaft, either in line with the single-width compartments, or two and two, or three and three, the compartments are doubled to form the double-width four or six-compartment shaft. In ground of good characteristics for strength and coherence, or under conditions where the supporting structure of the working will not be subjected to abnormal pressures resulting from swelling ground, it is probable that the double-width shaft is to be preferred for extensive underground operations. There is no question but that in the double-width shaft the ground can be more cheaply broken in sinking, while, other things being equal, the double-width shaft is the cheaper to construct; and while double stations are required, the compactness of each station is an advantage. If we assume single and double-width shafts of four and six compartments respectively, that are regularly framed with 12 by 12-in. timbers, each compartment of which is 5 ft. square in the clear, then the double-width four-compartment shaft will require but 96.5% as much ground to be broken as the single-width shaft, but 92% of the amount of timber will be required and 80% as much lining for the frames as for the single-width, while with regard to the six-compartment shafts but 95.4% as much rock will be extracted in sinking the double-width shaft as in sinking the single-width, while the former will require but 89% as much timber for the frames and 71% as much lining as will the single-width shaft. Therefore, if things are equal and the ground is suitable for the wider frames, the double-width shaft will be the most economical to construct. Where, however, the abnormal pressures due to swelling ground are to be met and resisted, the single-width shaft is to be preferred for the reason that the walls carrying the maximum pressures upon the frames are nearer together and the parts acting to support such pressures are shorter and therefore stronger under end-compression, since the strength of a column under end-compression varies inversely as its length.

There is no question but that by the use of skips of from 5 to 8 tons capacity, running in two compartments of 4 ft. by 4 ft. 6 in. section (which is the ordinary size of compartments of the Butte shafts), 1,000 tons can be hoisted in 24 hr. from varying depths to the limit set by Mr. Burrows. It would, therefore, seem that by dividing the 10 by 10-ft.-shaft in one direction by three 8 by 12-in. buntons, set edgewise with the shaft, as explained by Mr. Storms in his contribution, and in the other direction by a single center bunton, the two hoisting shafts can be properly arranged. This will furnish four equal compartments in the present 10 by 10-ft. shaft, one of which compartments would seem to be superfluous at the greater depths. Since a width of three feet in the clear would be ample for the hanging of all columns and pipes in the pump-compartment, the opposite side of this shaft from the hoisting compartments can be drawn in below the 320-ft. point to a total width of 8 ft. 2 in., thus giving two compartments of a width of three feet with a cross-sectional area of but 1.66 cu. ft. more than that of the projected 5 by 16-ft. single-width shaft. In this way the jog can be avoided, a donkey-hoist can be used in connection with the fourth compartment should it be necessary at any time for pump and other underground repairs, and the shaft can easily be enlarged to a full four-compartment shaft if at any time such enlargement should be deemed advisable. Under the conditions presented by Mr. Burrows I would favor the double-width shaft, although for the sake of additional stiffness and security in carrying the guides and for winding heavy loads, I would cross-brace at the division of the compartments those buntons to which the guides are hung, and for such buntons I would prefer 10 by 12-in. timbers instead of the 8 by 12-in. pieces that would exactly divide the 10-ft. shaft into two 4-ft. divisions. With the bracing of the parts furnished by framed sets, it is certain that ample strength for winding heavy loads would be obtained by the use of 8 by 10-in. timbers or even by the 8 by 8-in. pieces. That such shafts are entirely feasible under practical conditions the ample success of the Whiting or Red Jacket double-width six-compartment shaft of the Calumet & Hecla mines is sufficient proof.

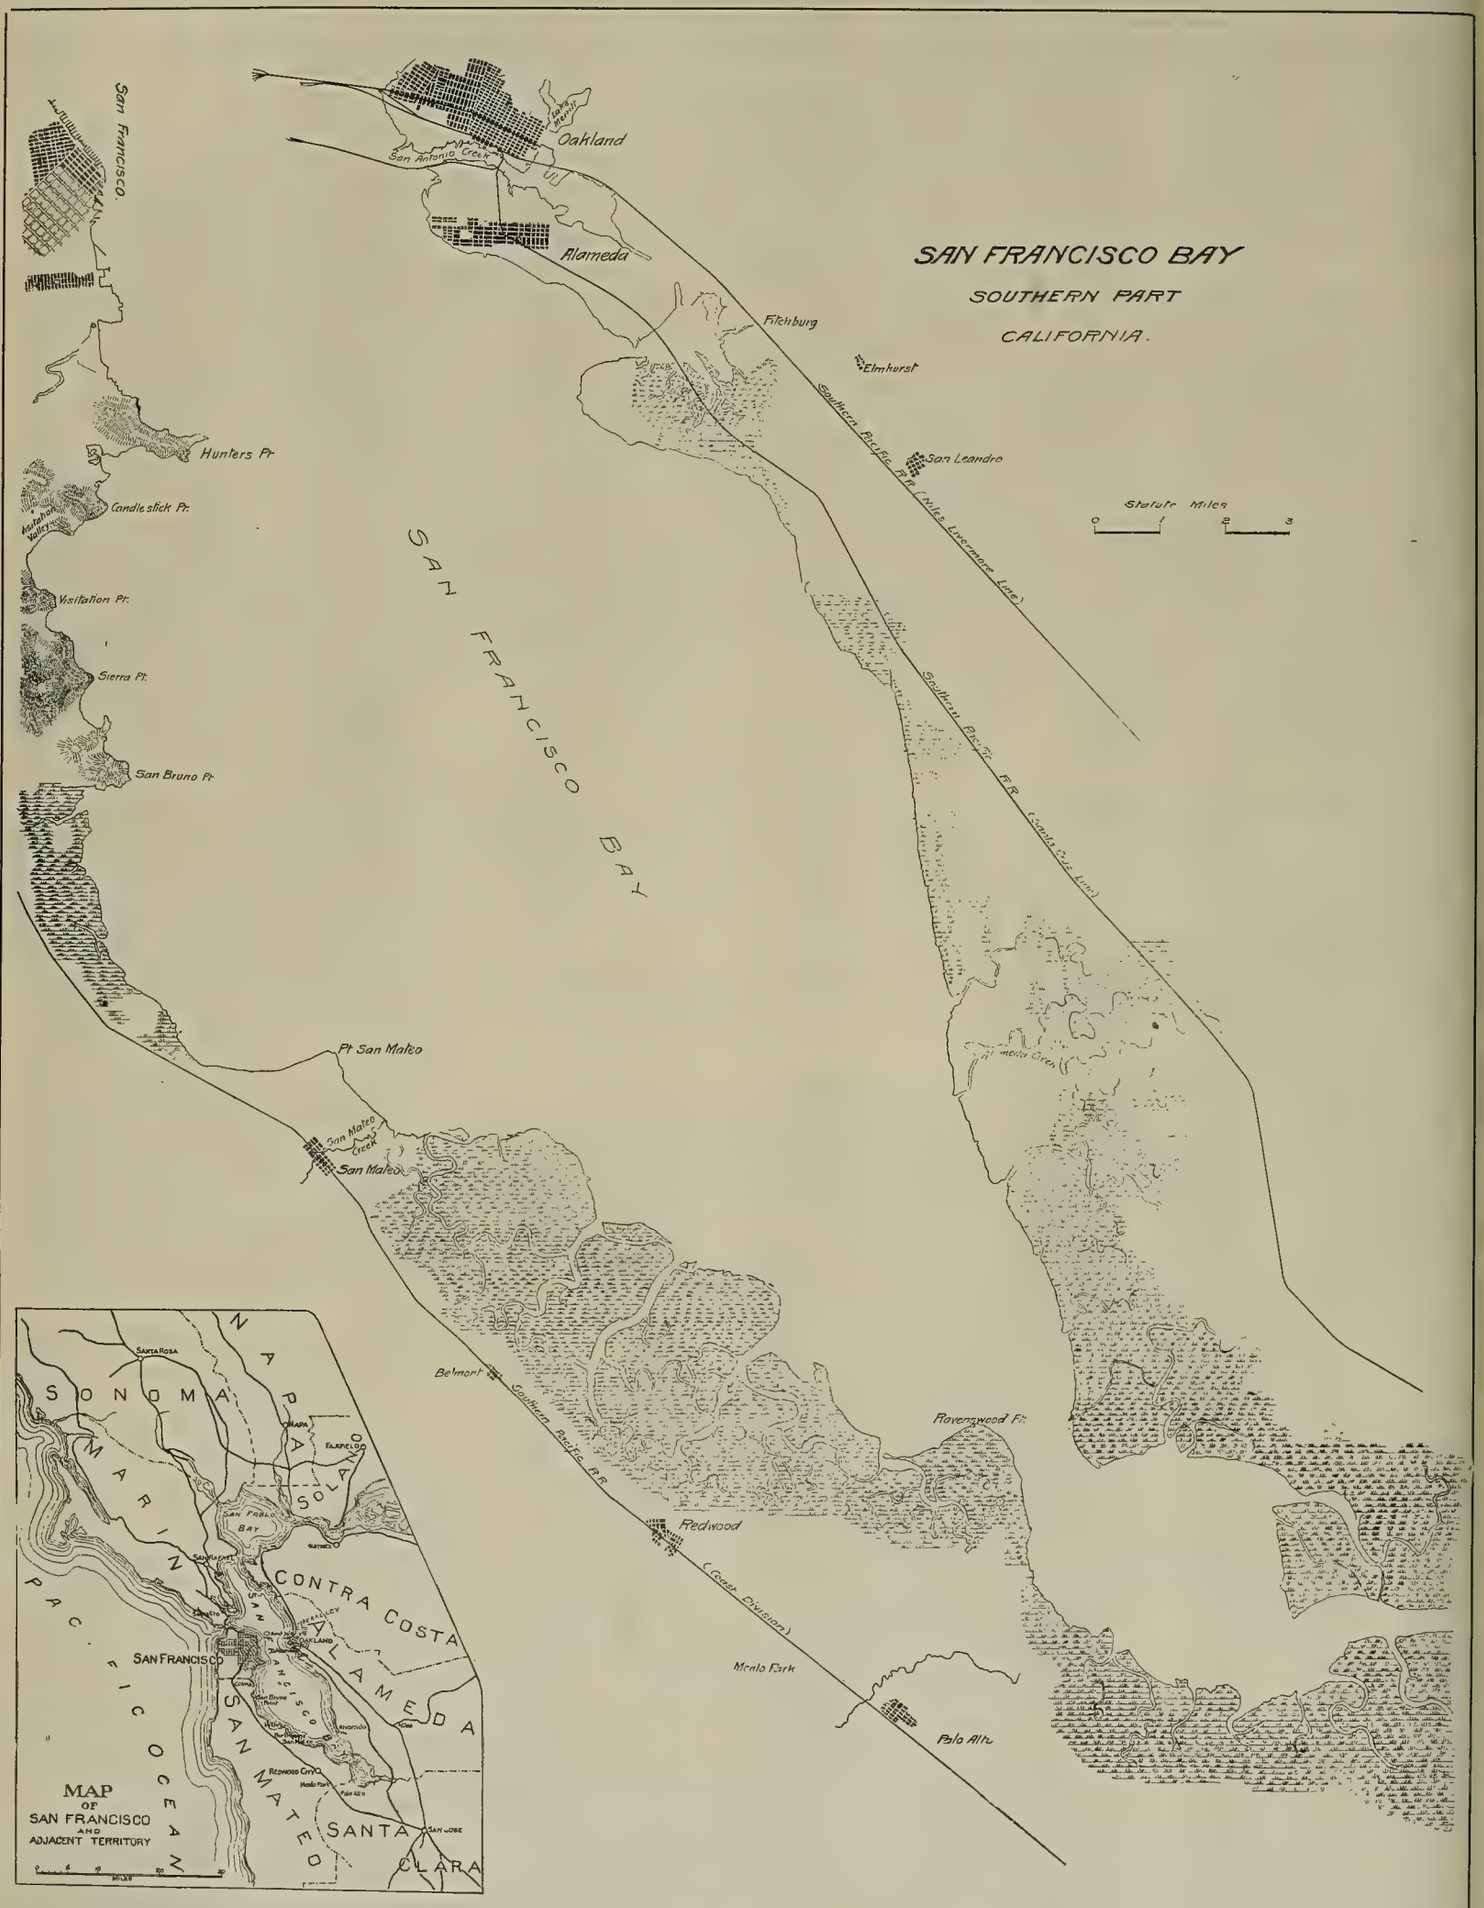
WILBUR E. SANDERS.

Helena, March 16, 1906.

[In regard to the use of two drills on a single bar, Mr. R. V. Norris writes saying that: "There is no difficulty whatever in the use of shaft-bars, at least up to 16 ft. long and carrying two drills. I have used them successfully under these conditions with 4½-in. Ingersoll-Sergeant drills, in ten shafts aggregating 8,780 ft. deep, the smallest of which was 12 by 16 ft. and the largest 16 by 51 ft. in excavation; the rock varied from a soft slate to an extremely hard, white conglomerate. In no instance was it found necessary to use tripods, nor have I heard any complaint of trouble with the shaft-bars." In connection with this discussion we give the size and arrangement of compartments of the Red Jacket shaft, 4,980 ft. deep, of the Calumet & Hecla mine. —EDITOR.]

THE method of handling explosives by the big mines in the Cœur d'Alene, especially at the property of the Federal Company, is commendable. The quantity required for a 24-hour day is thawed in a local outside magazine on wooden shelves by steam or hot-water radiators regulated to a very even temperature. It is handled entirely by one man, who distributes it through the mine between the night and morning shift, while most of the crew is out, where it is placed in short crosscuts from the main levels at some distance from the shaft. These crosscuts are cleaned of refuse daily. They are provided with an incandescent or covered light, and protected with heavy slat wooden doors that are kept locked, and nobody carries a key to them but the powder-man and shift-boss of the level, who hands out the powder, at shooting time, in small canvas sacks supplied with a loop or lap by which they can be swung over the miner's shoulder, giving him both hands free to climb with and handle his light and primer. Caps and fuse are always kept at considerable distance from powder stores.

AN extremely simple method of cutting a gauge glass is described in the *American Machinist*. It consists of taking a match, cutting it and thoroughly wetting the head. Then, after measuring the glass, put the wet match head inside the glass where it is to be cut and turn the glass several times until a ring is formed on the inside. Now hold a lighted match under this mark and the glass may be easily separated at the desired point. This method of cutting the glass should be more accurate than using a file to mark and break off the glass.



MAP SHOWING SITE OF THE NEW COPPER SMELTER.

The New Smelter.

On the opposite page we publish a map of San Francisco bay showing the site of the new copper smelter about to be erected. It is on the east end of San Bruno point, nine miles south of San Francisco, on the west shore of the bay. While the depth of water at this spot is only five feet and the locality is on the side away from the main railroad terminals, this site has been selected for the specific purpose of creating the minimum of annoyance.

The records of the weather bureau show clearly the direction of the prevailing winds; the tabulated statement which follows, gives the percentage of wind from the several points of the compass during five successive years:

Year—	North.	NE.	East.	SE.	South.	SW.	West.	NW.
1900	7	3	2	7	6	27	34	9
1901	11	2	2	8	5	28	36	7
1902	9	3	2	10	7	17	44	7
1903	12	4	2	8	4	16	43	9
1904	9	4	2	9	5	17	42	11

These figures speak for themselves. It remains but to add that in case of a westerly wind, which blows nearly half the year, the distance across the water, due east, is 14 miles; in case of a northwest wind, that is, during about a quarter of the year, the distance from San Bruno point to the marshes at the southern end of the bay is 27 miles. When the south or southeast wind blows toward San Francisco, the smoke will be deflected by the mountain, 1,100 ft. high, which crosses the peninsula just north of the smelter, so that the fume will be dispersed over the water. The northerly wind will take the smoke toward San Mateo and Burlingame; these are pleasure resorts and places where many of the wealthy have built beautiful country houses. From them come already protestations. But the wind that blows their way prevails only for about ten per cent of the time and never longer than 10 hours at a stretch, so that the nuisance will not be serious. During those rare periods when the air is slightly tainted, such men as D. O. Mills, Charles W. Clark and Walter Hobart will do well to remember how much of their wealth they owe to metallurgical processes, and if they are philosophic they will regard the whiff of sulphurous smoke as the incense blown from the altars of their prosperity. This matter is discussed at length on our editorial page.

To the community as a whole the establishment of this smelter is an event of pleasing importance. It will build up a town of several thousand people and, by treating 45,000 tons of charge per month, it will stimulate mining in all the States tributary to the Pacific coast. While it is designed to treat copper ores, the smelter will, of course, afford a market for the dry or silicious ores to be mixed with copper sulphides. San Francisco will benefit directly, for the tonnage mentioned—and this is likely to be increased—will represent the turning over of, say, half a million dollars per month in ore and half that amount in wages and supplies. The money that comes here in connection with this business is more likely to stay than in almost any other part of the world, because California is a country of homes—and homes, like smelters, require a modicum of money for their comfortable operation.

Separating Iron From Tin.—An ingenious method is now employed at the Loudon mill, Irvinebank, North Queensland, to separate the iron from the tin concentrate. The ore from the Vulcan mine contains magnetic iron, and the trouble always was to eliminate so undesirable a substance. The specific gravities of the tin and iron, however, so nearly approximate that separation was exceedingly difficult, and was never satisfactorily accomplished. James Tunnie, assayer to the Irvinebank Tin Mining Co., owners of the mill, proposed using electricity to overcome the difficulty, and with John Moffatt, who takes a keen interest in ore dressing, a scheme was evolved. Water containing the tin and iron was highly charged with electricity, which increased the magnetic influence of the iron, and this created cohesion between the iron particles. The ore was then run over vanners, and the united iron particles, irregularly joined, offered much greater resistance to the water, and were more affected by the vanning motion than the close-lying tin. As a result separation was easy, the iron particles readily leaving the table along with the lighter material.—*North Queensland Register.*

The gold output in South Africa for January and February was 836,306 fine ounces, as compared with 733,069 for the same period in 1905, and 578,326 in 1904, and 151,746 in 1902. The employment of additional Chinese labor has been stopped, which may check the increasing production. It has caused a heavy fall in South African shares, as there is a possibility that the Chinese already there may be sent home.

Spring and well waters contain in 10,000 parts about $\frac{1}{10}$ part solid matter, consisting largely of lime salts. Well-water that contains much lime is called hard. Well-water also contains some carbonic acid and air in solution, both of which give it its refreshing taste; distilled water tastes flat.

Iron vs. Wood for Cyanide Leaching Tanks.

Written for the Mining and Scientific Press by Francis L. Bosqui.

The following facts in regard to iron and redwood leaching tanks for the cyanide process will determine which type is best to use in a given locality.

In warm countries, where the winters are not severe enough to require housing the plant, the iron tank is to be preferred. Iron tanks are more expensive in first cost and erection than redwood; they are also more expensive to maintain, owing to the necessity of frequent coating to protect both the iron and the cyanide solutions. They must be set up with special care and subjected to water-tight test, as leaks are difficult to stop, especially in the bottom, after the filter has once been laid. A serious objection, not generally recognized, is the lack of rigidity of iron tanks when under pressure of a charge of ore, and the tendency of the periphery to shift from the line of the true circle. This shifting or bulging will take place during the filling or after solution is applied, and is due to the charge not being uniform in density and of varying pressure at different points. Such a variation, with the consequent yielding of the iron, will oftentimes produce cracks throughout the charge of sand. This prevents uniform percolation and is a serious matter. It can be prevented, however, in great measure by using sufficiently heavy material and reinforcing the tanks with bands of angle iron.

The redwood tank is perfectly rigid, and is much cheaper in first cost and maintenance than the iron tank. It does not require as frequent coating with protective paint. There is a popular prejudice against wooden tanks owing to their alleged greater liability to leakage, and their absorption of values. The leakage may be prevented by good workmanship in setting up the tank. The redwood leaching tanks at the Smuggler-Union cyanide plant in Colorado are 40 ft. in diameter, and are absolutely tight; and I am quite positive that the same may be said of the large 54-ft. tanks at the Homestake. Rare cases have been reported of losses from absorption. I investigated this point several years ago. The results of the tests made on that occasion are quoted herewith from my article in *The Engineering & Mining Journal* of February 26, 1898.

A piece of redwood 5 ft. 2 in. long and 2½ in. thick was submerged for three weeks in a gold solution at Bodie. Weighing before and after submersion showed an absorption of 2⅜ lb. in 80 hr., equal to 22% of the original weight. Assuming that a tank weighing six tons would absorb as much as 50% of a $5 cyanide solution, the absorption would amount to three tons, or $15—an almost imperceptible loss in a plant treating several thousand tons per month.

Another way to account for loss of gold by absorption is to assume that the absorption is cumulative—that is, in a leaching vat submitted to intermittent contact with solution, the gold is deposited in the wood by a series of partial evaporations. To determine which was accompanied by the greater loss by absorption — continuous or intermittent contact—and whether either was responsible for any considerable loss, the following tests were made:

First series (continuous contact).

A. A piece of dressed redwood, thoroughly seasoned, weighing 2 lb. 2 oz. and exposing 180 sq. in. of surface, was submerged for three weeks in a solution carrying an average of $5 per ton in gold. The wood was then taken out and dried, and reduced to charcoal in a clean solder stove and further reduced to ash in a new assay-muffle. The ash was carefully fluxed, cupeled, and the button weighed, with the following results, silver being valued at 50c. per ounce:

	Gold.	Silver.	Total.
Actual absorption....mg.	1.65	2.75	4.40
Absorption per ton of wood....grams	1.552	2.588	4.14
Value absorbed per ton of wood....	$1.03	$0 01	$1.07

B. A piece of seasoned dressed pine weighing 3 lb. and exposing 180 sq. in. of surface was submerged at the same time as the redwood and subjected to the same conditions:

	Gold.	Silver.	Total.
Actual absorption....mg.	1.7	2.6	4 3
Absorption per ton of wood....grams	1.133	1.733	2.866
Value absorbed per ton of wood....	$0.75	$0.02	$0.77

C. A piece of rough pine weighing 2 lb. 7 oz. and exposing 144 sq. in. of surface was taken from the bottom of a discarded screen-frame, which had been constantly and directly exposed to a strong solution (averaging $5 per ton in gold) for a period of eight months, and again for a period of four months:

	Gold.	Silver.	Total.
Actual absorption....mg.	9.5	10 8	20 3
Absorption per ton of wood....grams	7.794	8 86	16.654
Value absorbed per ton of wood....	$5.18	$0.14	$5.32

Second series (intermittent contact).

A. A piece of dressed redwood weighing 2 lb. 7 oz. and exposing 180 sq. in. of surface was subjected to intermittent submersion in a strong gold solution for three weeks. The piece was left in the liquid for 16 hr. in 24, and then removed and dried in the sun for the other eight hours:

	Gold.	Silver.	Total.
Actual absorption....mg.	4.8	2.1	6.9
Absorption per ton of wood....grams	3.657	1.6	5.257
Value absorbed per ton of wood....	$2.43	$0.02	$2 45

B. Two pieces of rough pine, weighing together 3 lb. 4 oz. and exposing each 160 sq. in. of surface, were taken from near the top of the disused screen-frame from the gold tank. This portion of the frame had been alternately exposed and dried for 12 months, and was probably about one-half of the time under solution:

	Gold.	Silver.	Total.
Actual absorption....mg.	6.7	13.7	20 4
Absorption per ton of wood....grams	4 122	8 429	12 551
Value absorbed per ton of wood....	$2.74	$0.13	$2 87

It may be noted that the portion of the screen-frame subjected to long continuous submersion showed the highest absorption—$5.32 per ton of wood—and that the piece of redwood exposed intermittently to solution for three weeks indicated almost the same degree of absorption as the top portion of the screen-frame exposed for several months.

The indications are that in no case would the absorption be much of a factor in gold losses, even in a vat of unprotected surface.

Origin of Coal.

Coal is a rock of organic origin, containing oxygen, carbon, hydrogen, and other constituents. If air be admitted to vegetable substances, when at a high temperature, they take up oxygen and are gasified; and if heat be applied without air, as in a retort, the hydrogen and oxygen are driven out, and the carbon remains. This process is known as dry distillation, and in this way coal has been formed from land and water-plants, especially the latter. The clay-slates, containing mica and potash, afforded a rich soil, and the moisture in the air fostered the growth of the plants. As the more perishable decayed, they furnished nitrogen to plants of higher organization, such as *sigillaria* and *lepidodendra*, in which the coal measures are rich. A subtropical climate, with a temperature of 68 to 77° F., seems to have been universal, and an atmosphere charged with carbon dioxide and water-vapor. To secure this moderate and equally diffused warmth, it has been supposed that the climate was independent of the earth's position toward the sun, and that the inclination of its axis was not so considerable as it is now. This luxuriant vegetation was probably transformed into coal in its original position.

When air reaches a dead plant, and it cannot be gasified by oxidation, a substance known as *humus*, containing carbon and lime, is developed inside the plant-cells. *Humus* is found in peat, and it is in the growth of peat, in which bubbles of carbon dioxide and marsh-gas rise to the surface of bogs and burst, that the formation of coal may still be studied. In the process of carbonization, the gases of marsh-plants, hydrogen, oxygen and their compounds, were driven off, and this is still going on in coal mines; in the later brown coal-seams, carbon dioxide, and in the earlier stone coal seams, marsh-gas was liberated. Upon this fossil and carbonized vegetation strata of clay and sandstone supervened, heat was generated, the pressure was high, the water rapidly driven out, and dry distillation with decomposition took place. The slower the process, the poorer was the coal in oxygen and hydrogen, and the richer in carbon. Geological upheavals, dislocations, faults, etc., caused different degrees of carbonization, and where the pressure was greatest the coal was converted into anthracite. Bituminous coal is of later formation, and brown coal still more recent. The quality and heating value of the latter varies greatly, showing that it was carbonized at different stages; but all brown coal is low in carbon and contains a high percentage of water and ash. Lignite, the latest of all coal, still retains its woody structure.

The origin of coal and peat has been ascribed to fermentation, and a certain similarity in the process of generating alcohol and stone-coal, and in the products, has been pointed out. The writer considers that this applies only to the earlier stages in the formation of coal, and that the temperatures attained are too high to allow of the working of fermentation-agents.

The spontaneous combustion of coal cannot take place without heat, and the presence of oxygen or air and the process of generating the one and absorbing the other is known as oxidation. Heat is a movement of atoms and molecules, increasing their distances from each other, and the marsh-gas, carbon dioxide and nitrogen, enclosed in the pores of the coal, are liberated. Pyrite, in the coal, also favor spontaneous combustion. It is oxidized into sulphurous and sulphuric acids, the heat developed by chemical action dries and heats the coal, and if air be admitted it ignites and burns.

Coal absorbs atmospheric air, condenses it, and increases in weight; while, if disintegration continues, the weight falls, carbon dioxide and hydrogen are set free, and the heating value of the coal is reduced. The capacity of a given coal for spontaneous combustion may be determined by the amount of bromide with which it is able to combine. The chief substances in the coal which contribute to combustion by their readiness to unite with oxygen are the hydrocarbons, and the oils produced during natural decomposition.—F. Janda, *Osterreichische Zeitschrift, B. und H.*

The Effect of a Snowslide.

Written for the MINING AND SCIENTIFIC PRESS by STEPHEN L. GOODALE.

On Saturday evening, March 17, 1906, at 7:10 P. M., a snowslide demolished a large portion of the stamp-mill of the Camp Bird, Ltd., at Ouray, Colorado. For a number of days previous the fall of snow had been exceptionally heavy and continuous; so that the depth of freshly fallen, unpacked snow was very great, and was the cause of the unusual violence of this and many other slides in the neighborhood.

The slide ran straight from the top of Mt. Hayden, in its course taking out first some thirteen towers on the wire-rope tramway; then, leaping down a high cliff, it struck the hillside, and took out several warehouses, a coal-shed and large water-tank above the mill and wrecked the mill itself. Lastly, a small bunk-house, about 200 ft. from the stamp-mill, was struck with sufficient force to crush in the lower story on one side, and was saved from more complete destruction only by a large rock that split the slide and reduced its force before the house was hit.

The lower story of the bunk-house had been devoted to a reading-room. Seven men were caught there in the snow and debris, but all were rescued in a short time and without serious injury.

Electric power lines and all other wires to the mill had been taken down by slides elsewhere earlier in the day; so, as the mill was not running, only three men were inside at the time. One of them, Andy Eke, was untouched, though caught in the wrecked portion of the mill; one, Strickland, was dug out some two hours later from under about three feet of snow and timbers, with only slight bruises; and one was killed outright. Eke was too scared to answer the calls of the rescue party for some minutes. Strickland said that after the first warning crack, he would have had time to yell—but no more—before he was buried; and that he did not even yell, so quick was it. Most of the noise made by the slide was the cracking of timbers in the buildings struck. Many of these slides run with but little noise and with no previous warning. I saw the so-called 'water-hole' slide—whose path is down the side of Mt. Hayden into Cañon Creek, run, at 3:20 that afternoon, from the mill, a distance of perhaps a half mile. This was a big slide, and took out all the wires to Ouray, but there was practically no noise from it audible at the mill, though the whole cañon quickly filled with a mist of snow, which was some minutes in clearing.

Fig. 1. Stamp-Mill Destroyed by Slide.

Strickland was dug out of the snow by the Huntington mill on the extreme right of this photograph.

Accompanying photographs show something of the condition of the stamp-mill and bunk-house after the slide. The two warehouses were carried onto the vanner floor of the mill and nearly buried there under snow. The boiler-house and the end of the stamp-mill next to it were not destroyed. The opposite end of the building, housing four Huntington mills, was completely wrecked. A middle section of the mill was knocked out entirely, and between this and the Huntington end, a section, housing 20 stamps, was left partially standing. The step-like affair in the middle of one photograph (Fig. 1) is an overturned piece of roof; to the right of it can be seen one end and the roof of warehouse No. 1, which formerly stood 200 ft. up the hill on a spot a little to the right of the area included within the photograph. The bunk-house was left standing, one side crushed in below. See Fig. 2.

The slide ran in a well-defined track through the forest, but had never been known to run with anything like the force and volume it had on this occasion; and the site of the Camp Bird mill had been generally considered to be one of the safest places in the San Juan, so far as this particular danger was concerned. Snowslides resemble unloaded guns. They usually run in certain known places and not elsewhere. Unloaded guns usually do not go off. When either abandons its habits something is apt to be doing.

At the Camp Bird mine a huge slide tore out some of the timber sheds, but did no further damage.

Fig. 2. Bunk-House, the Day After.

On Tuesday morning, between 1 and 2 A. M., fire was discovered by the night watch in the upper part of the boiler-house, and all of the stamp-mill that had been left by the slide was totally destroyed by the flames. It was only with great difficulty that the concentrate dryer, connected with the stamp-mill by the overhead passageway shown to the left in Fig. 1, the machine-shop and the blacksmith-shops and cyanide plant were saved from burning; as the water-storage tank used for fire protection had been destroyed by the slide, and only a tank of water used for the cyanide mill was available. The destruction of the stamp-mill and boiler-house by fire was complete. For three or four days in certain parts of the smouldering ruins the odor of quicksilver was very strong. The amalgam on the battery plates was pretty thoroughly parted and the 'quick' driven off, leaving a gold plate on the copper. In the clean-up pans most of the amalgam had also been parted, and the gold was left as a well-retorted dirty sponge; but a little amalgam and quicksilver were also left.

The cyanide mill was not injured by either avalanche or fire. The slope of Mt. Hayden is such that a slide starting above this mill would be deflected by a shoulder of the mountain and turned to one side or the other. The work of clearing up is already under way, and the construction of a new mill will be pushed as rapidly as possible.

PANAMA CANAL.—The total volume of excavation for the sea-level plan is estimated at 231,000,000 cu. yd., of which 110,000,000 yd. is in the Culebra cut, 8 miles long. For the lock canal project the total quantity of excavation in the Culebra cut is reduced to less than 54,000,000 cu. yd. It is estimated that the construction of the Gatun locks, which will require 3,660,000 cu. yd. of excavation and 1,300,000 cu. yd. masonry, will take about as long a time as the excavation of the divide cut. The total estimated cost of constructing the lock canal recommended in the minority report is in round numbers $140,000,000; and the time necessary is estimated at seven and one-half to nine years. In comparison, the estimate of the majority of the Board for its sea-level project is $247,000,000, and from 12 to 15 years is the estimate of time required for its construction. It should be stated here, however, that both these estimates are for a much deeper and wider canal than any heretofore contemplated. This increase in dimensions is made necessary by the wording of the Spooner Act, which provides that the canal "shall be of sufficient capacity and depth as shall afford convenient passage for vessels of the largest tonnage and greatest draft now in use, and such as may be reasonably anticipated." The Isthmian Canal Commission of 1901 proposed a canal with a bottom width of 150 ft. and a depth of 35 ft. This was, it may be noted, a great increase over the original De Lesseps project, which was for a canal 29.5 ft. deep with a bottom width of 72 ft. The lock chamber adopted by the 1901 commission was 84 ft. in width and 740 ft. in length.—*Engineering News.*

A FREAK of giant powder was witnessed by the crew of the Congress Consolidated Mines Co.'s train in Yavapai county, Arizona, recently. They were taking up a lot of powder on the little train and in a low-sided box car. In some manner a box of the powder was caused to fall from the car and roll under the wheels. The box containing the powder was cut in two pieces and two sticks of the dynamite were exploded, but the remainder of the powder refused to join in the disturbance, which would have resulted in great damage and perhaps fatally to the men on the train, as it is likely that if the broken box had exploded the other powder on the car would have followed suit.

The Assay of Cyanide Solutions.

Written for the Mining and Scientific Press by William Magenau.

About a year ago I had occasion to search for an extra rapid method for determining gold in cyanide mill solutions, to be used in controlling the operations of an agitation plant which handled charges of 100 tons each. The process involved special chemical treatments, and washing by decantation; and a quick solution-assay was imperative right through. As a basis, I gathered from textbooks and files of the technical press all suggestions along this line, and tried but a few before finding one which, with some modifications, answered well.

It may interest cyaniders to know this method, especially as they may have had the same discouraging experience as I had with the method as published. It was described in the *Engineering and Mining Journal* of March 28, 1903, by Alfred Chiddey; in substance it was as follows: Add to four assay-tons (or more) of the solution 10 c.c. of 10% solution of lead acetate; then four grams zinc shavings; boil a minute; add 20 c.c. HCl (strong). When action has ceased, boil again and decant from the ball of spongy lead which has been compacted a little with a glass rod, and wash same by decantation. Transfer to a piece of filter-paper, roll into a compact ball, and place (without drying) on a hot cupel in the muffle.

Mr. Chiddey states that a result can be obtained in 25 min., which I failed to confirm. It is certainly the experience of most of us that it requires several times that length of time to bring four assay-tons (120 c.c.) of solution twice to a boil, to *dissolve four grams Zn in HCl*, to conduct a cupellation, then part and weigh, to say nothing of manipulation. But far from making any speed records, I could not get the method to work at all, following the scheme to the letter. Instead of the lead coming down spongy, it was finely divided and showed no tendency to agglomerate, and had to be filtered out to collect it at all, which it was the very merit of the proposed method to avoid. But the precious metals were perfectly precipitated, and realizing the advantages of the scheme, I experimented with other proportions of reagents than those given and got good results from the following:

Take in a large beaker (about 600 c.c. capacity) five or ten assay-tons of solution, and if it is very weak in KCy add enough of strong pure solution to bring it up to about 0.5% strength. Add 10 c.c. of a 10% solution of lead acetate, slightly acidified with acetic acid (12 c.c. if 10 assay-tons were taken); then add by rough measure on the point of a spatula between 0.3 and 0.4 gram (not more) of zinc dust, this being sufficient to precipitate all lead present and leave an excess of zinc to act on Au and Ag. Stir and bring to a boil; then add 15 c.c. strong HCl and leave on the hot plate until excess Zn is dissolved and lead has gathered into a sponge. This will take but a few minutes, and the assay should then be taken from the heat, else the lead will begin to dissolve. Now gather the lead a little with a glass rod whose end has been flattened while hot, or with the fingers encased in a rubber cot, decant rapidly, wash by decantation two or three times with large quantities of water, pick up the lead (which should be soft and strongly inclined to stick together when pressed) in the fingers and compress it into a ball, which place upon a piece of lead foil 1½ in. square. (Using filter-paper instead of lead-foil, the spongy lead is apt to separate in the cupel). Fold up in such a way as to leave an egress for steam, and drop into a hot cupel in the muffle, having first added a bit of silver, if the assay is for gold only.

The solution on which this method gave excellent results, and checked perfectly with the old evaporation methods in minimum time, carried about 0.075% KCy and from nothing to one ounce Au per ton with almost no Ag. It is possible that Mr. Chiddey's method, as published, works better on other solutions, though it is not clear why so much as four grams zinc need be used, taking a long time to dissolve, when one-tenth as much, in the shape of 'dust,' is ample. Perhaps different proportions of reagents will be necessary to suit each case, but operators will find it worth a little experimenting to secure a method which involves no filtration, no fusion nor scorification, is accurate and rapid, easily performed and equally suited to large batches and single assays.

The method may be used without application of heat, as the precipitation of precious metals is perfect in the cold, but the lead does not agglomerate well and the excess zinc takes longer to dissolve. When done this way, the precipitated lead (plus Au and Ag) must be filtered out and the paper, unwashed and still wet, rolled up in a piece of lead foil about two inches square and dropped into a hot cupel.

It may be of further interest and a convenience to have the list of methods which I gathered, chiefly from the American technical journals of the past eight years; cyanide chemists may be encouraged thereby to give them a trial, and let the profession know the results. Gold determination has been the chief concern, but these methods, except where noted to the contrary, may be used equally well for silver.

I. METHODS INVOLVING CRUCIBLE FUSION OR SCORIFICATION BEFORE CUPELLATION.

1. *Evaporation* in a lead-foil tray, either direct, or after concentration to small bulk in a porcelain dish, the finish to be conducted at a very low heat. The tray is rolled up so as to enclose the residue, and is scorified with test lead before cupellation, parting and weighing. With small charges (say one assay-ton) of solution carrying only small amounts of dissolved matter, the scorification can be omitted. A variation of the method which avoids the lead tray, is to sprinkle into the charge of solution (in a porcelain dish) 20 grams litharge, in such a way as to cover the bottom; then evaporate to dryness, and scrape the residue with a spatula into a crucible containing 10 grams sodium bicarbonate, five grams borax glass and one gram flour or argol. The dish can be thoroughly cleaned by moistening with dilute nitric acid and mopping out with small pieces of filter-paper which are added to the crucible. Fusion results in a lead button, which is cupelled, etc. The evaporation method is the oldest in use, and when carefully done is accurate. It involves much time, but little and simple manipulation.

2. *Precipitation as Sulphide in Acidified Solution.*—This is given in the *Engineering and Mining Journal*, November, 1898, by Henry Watson, and is stated to be quick, accurate and economical.

Acidify five or 10 assay-tons solution with HCl and heat to boiling; while boiling, add a solution of two grams lead acetate and pass a current of sulphuretted hydrogen until all Pb is precipitated. Allow to cool a little while, still passing H_2S, then filter, precipitate, dry and reduce to a lead button by either scorification with lead test or fusion with fluxes in a crucible; cupel, etc.

3. *Precipitation by Cement Copper in Acid Solution.*—Albert Arents in *Trans.* A. I. M. E., Vol. XXXIV, p. 182: Add a few cubic centimeters H_2SO_4 to six or eight assay-tons of solution, stir well, and add one gram (not much more nor less) of commercial cement copper. Boil hard for 10 min. Filter through a large gray paper without washing. Place in an assay crucible one-third of a fluxing mixture consisting of 30 grams litharge with usual amounts of soda, borax and reducer, and on the drained filter, another third. Then pick up the filter, tuck it into the crucible and cover with the remaining third of flux. Now fuse, cupel, etc. Instead of cement copper, a solution of $CuSO_4$ may be added and then some aluminum foil. Boiling the assay for some time brings down the copper. The aluminum foil should be added to the fusion of filter.

4. *Precipitation by Silver Nitrate.*—Credited to A. Crosse on p. 161 of Gaze's book on the 'Cyanide Process.' Add an excess of silver nitrate solution; filter and wash; dry filter and either scorify it with test-lead after incineration, or fuse with fluxes in a crucible, cupelling the resultant lead button. This method, of course, can be used for Au only. Gaze also gives a modification of this which employs a bichromate of potash indicator to determine when there is an excess of Ag NO_3, and directs that a few grams of zinc-dust be added beside. After stirring well, an excess of H_2SO_4 is added. Then filter and wash, dry, fuse and cupel; or the incinerated filter may be cupelled direct when wrapped in lead-foil. Mercuric chloride may be used instead of silver nitrate.

5. *Precipitation by Copper Salt.*—Maurice Lindemann in *Engineering and Mining Journal*, July 1, 1904. Heat 10 assay-tons until quite hot: add ammoniacal copper nitrate solution to a permanent blue; carefully acidify with H_2SO_4; stir and filter immediately. Dry and incinerate the filter, fuse or scorify, cupel, etc. Some chemists claim this method will not work on foul solutions

Grant D. Miller in *Engineering and Mining Journal*, June 23, 1904, treats 34.3 assay-tons (one liter) of solution in a two-liter flask with one to two grams copper sulphate. After shaking well, add 10 to 15 c.c. strong HCl and shake well again. Filter, dry, and incinerate, fuse, cupel, etc., as before.

6. *Precipitation by Zinc Shaving or Dust in Acid Solution.*—H. L. Durant in *Jour. Chem. & Met. Soc.* of S. A., December, 1902. Place a large measured bulk of solution in a flask, acidify strongly with H_2SO_4 and bring to a boil. Add 30 grams zinc shaving, about five grams at a time, waiting with each addition until all that previously added is dissolved. Keep solution strongly acid throughout. When all has been added and dissolved, put in one gram precipitated silica to collect floating matter, filter through double papers, dry and char the papers on a scorifier, and then add test-lead, scorify and cupel. This method can be used for Au only, since Ag dissolves as sulphate.

A much more practical method is used in the Black Hills and elsewhere. To eight assay-tons of solution are added enough silver nitrate solution to furnish inquartation for gold; then 0.33 to 0.5 gram zinc-dust and sufficient H_2SO_4 to react completely, say 5 to 10 c.c. Stir a little and filter through an ordinary paper, dry, incinerate, and fuse in a crucible with litharge and reducer for a lead button, which is cupelled, etc.

7. *Precipitation by Emulsion of Zinc-Dust in Lead Acetate.*—This method was used in some large mills in Colorado a few years ago, but I am unable to give more than a bare outline, and do not know how it will work out. Make a thin paste of zinc-dust in a strong solution of lead acetate and add about 8 c.c. of this to 20 or 30 assay-tons of solution. Agitate and let stand for a time. Filter and add dilute H_2SO_4 to the filter and wash. Dry, filter, incinerate, fuse with litharge (or scorify with test-lead) and cupel, etc. This is virtually the same as suggested for cold treatment of the modified Chiddey scheme, already described, though differing in manipulation.

II. METHODS WHICH GATHER PRECIOUS METALS IN LEAD THAT CAN BE CUPELLED DIRECT.

1. *Evaporation* either conducted entirely in, or finished in, a lead-foil tray, when solution is comparatively small in amount (one to two assay tons) and contains only small amounts of dissolved salts [see I (1)].

2. *Chiddey Method*, or modification described. This seems to be really the only method properly and exclusively in this class.

III. COLORIMETRIC METHODS (for gold only).

1. *By Stannous Chloride Following Precipitation and Re-solution of Gold.*—Prister in *Jour. Chem. Met. & Min. Soc.* of S. A., December, 1903, gave a method which would seem too long for practical use. He adds to the acidified and boiled solution under assay a few cubic centimers of a 10% solution of $CuSO_4$ containing 20% NaCl, and acidified with acetic acid after having been boiled 10 min. with copper shaving and cooled. The precipitate resulting from addition of this reagent is filtered out and re-dissolved in a KCy solution, and to this is added a half gram of zinc-dust. After agitation for a few minutes, this is filtered off and treated on the filter with dilute HCl. Treatment of the same filter with aqua regia (minimum quantity) dissolves the gold, and in the solution an excess of strong stannous chloride solution gives the 'purple of Cassius' test, which may be compared with standards.

Later Prof. Prister published a simplification of this scheme which reads better. The solution under test is brought up to 1% KCy. To 234 c.c. (eight assay-tons) add one gram zinc-dust and heat to boiling. Filter; pour on filter 20 c.c. hot 10% H_2SO_4, repeating until all the zinc is dissolved. Treat residue on the filter with 10 c.c. hot aqua regia (6HCl, $2HNO_3$, 6 water), passing the 10 c.c. repeatedly through same filter at a boil. Collect in a test tube, cool and add a "few drops" stannous chloride as before. Prof. Prister does not say how he avoids disintegration of the filter by action of hot aqua regia. From work I have done with 'purple of Cassius' tests on aqua regia solutions of gold, good and constant colors cannot be obtained unless the acids are present in small amounts and a large excess of stannous chloride is used.

2. *With Stannous Chloride Without Previous Precipitation of Gold.*—Henry R. Cassel has given a promising quick test as follows: To 10 c.c. of solution in a test-tube is added 0.5 gram potassium bromate, then pure strong H_2SO_4 slowly until action starts. When action has ceased, add drop by drop a strong solution of stannous chloride, until the solution is just colorless. In about half a minute the purple color will form. Mr. Cassel says the test can be performed in three minutes, and is delicate to a value of a few cents per ton of solution. By concentrating by evaporation very low grade solutions or diluting those too strong in gold, this method may apply to a wide range.

He also used other agents than potassium bromate as a destroyer of the interference of cyanogen, namely, potassium chlorate and HCl, or H_2SO_4, with long boiling; potassium bromide followed by sodium peroxide and neutralization with H_2SO_4, after which HCl and stannous chloride are added to give the color. This last acts well. Another scheme is to add to the solution one-third its bulk of strong ammonia and then neutralize with strong H_2SO_4. The solution will then react with stannous chloride. For quantitative work, standards must be prepared, and to make these durable is a great difficulty of the method. Considerable skill is also needful.

IV. ELECTROLYTIC METHODS.

1. *Deposition on Lead.*—In *Trans. Inst. of Min. & Met.*, May 16, 1905, F. B. Stevens gives a method which does not appear to possess any advantages over the chemical processes in points of time, convenience or accuracy. Fourteen to twenty assays of 10 assay-tons each (292 c c.) are electrolyzed by current from 110-volt lightning main for four hours, using a lead-foil cathode of cylindrical shape 2½ in. high and 1 in. diam., with three V notches around the bottom, and a large iron nail for anode. To each assay 12 to 15 c.c. of strong ammonia is added. The cathode should be covered with one-half inch of solution. Twenty assays give just right resistance, and with less than 14, electric lamps must be put in circuit. With a current varying from 0.06 to 1.2 ampere, according to foulness of the solution, the gold comes down bright. The cathode is washed, dried, rolled up and scorified with test-lead before cupelling.

The only figures given for completeness of precipitation state that a solution carrying $10 to $15 in gold will be cleaned to about 10c. in four hours. If this is the best that can be done, the method is not

applicable to low-grade solutions. It would seem that cupellation of the cathode might be made without preliminary scorification.

It will be noticed that for most of the above methods charges of 10 assay-tons, or less, are recommended, which will perhaps seem inadequate to some, particularly South African operators. Most English authorities (as Julian and Smart) insist that only very large charges be used. The authors named say not less than 30 assay-tons and up to 200. In America balances can readily be purchased which are sensitive to 0.01 mg., or even one-fourth of this. Taking the former figure, 200 assay-tons would give gold results accurate, so far as the weighing is concerned, to 0.001 per ton. What conceivable use such a degree of precision can be is not stated. Even 30 assay-tons would weigh down to 0.007, which is far finer than available methods of sampling and measuring ore and solution tonnages justify. Ten assay-tons give a bead weighable to 0.02, and nothing beside investigation work need be concerned with less than this.

The Wunsan Mines of Korea.

Written for the MINING AND SCIENTIFIC PRESS by W. G. ANDERSON.

Occasionally we hear of the mining that is being done by the Oriental Consolidated Mining Company, but little is known of their history and the difficulty and hardships in getting the enterprise properly started, on account of the remoteness of the locality and the difficulty of teaching the natives modern mining methods. This was a task greater than the ordinary man's ability. To Leigh Hunt, H. F. Meserve, Dan Buckley and Duff brothers belongs the credit. They were the pioneers. The writer, though not one of the first, was a close follower.

Teaching the natives how to use the shovel was one of the hardest tasks. Their language was difficult to learn, but it has been mastered, and in a comparatively short time the Koreans have become good miners, engineers and blacksmiths. The Korean method of working a mine is to build a fire on the ore, and, when it gets hot, to throw water on it for the purpose of breaking it; then it is carried to a flat stone, where it is ground by a half-rounded stone with two poles lashed to it so that two men can rock it, while another man feeds the ore between the stones; when ground fine enough, the pulp is panned to recover the gold. The natives worked their mines by such methods to the water level. At some of the mines there were thousands of natives working in this way.

Shortly after the war between Japan and China, the Emperor of Korea concluded to work the mines with modern machinery. He employed two white men, purchased a 10-stamp mill, with 600-lb. stamps. It was a very inferior mill, an old rattle-trap. The two men employed proved incompetent; they consumed a great amount of time in getting the mill to the mines. Not having the ability to set it up, the Emperor discharged them. About this time Mr. Leigh Hunt arrived in the Orient. He personally examined the mines, obtained a large concession from the Government, erected the 10-stamp mill at Chittabalbie, set up a whim, which was worked by a bull, sunk the Korean shaft, which was noted for its crookedness, and raised the water with hand-pumps. The pumping was done in stages, lifting the water to earthen crocks set at intervals in the shaft, not having barrels for this purpose. In this way, eventually a level was cut below the Korean workings. Shortly after the mill started the cam-shaft broke; a new one was needed and San Francisco was the nearest place where one could be obtained. It reached Chemulpo all right, but here it had to be re-shipped on a junk, which sank within 40 miles of the mines. Despite these and hundreds of other difficulties, they have conquered. They have now 200 stamps running on their concession. They have taught the natives how to mine and opened the country, so that now its great mineral wealth can be easily extracted.

Korea has many inducements to the mining world, in copper and gold, with the advantage of good and cheap labor; also a healthy climate. The pioneers have blazed the trail.

LEAD is used medicinally mostly for external applications for disorders of the system that manifest themselves upon the skin. Lead acetate is an internal remedy for certain fevers. Lead carbonate and lead iodide as well as lead oleate are used in ointments, plasters, etc.

Labor in Mexican Mines.

Written for the MINING AND SCIENTIFIC PRESS by EDWIN H. DAVISON.

The hiring of labor in Mexican mines and the manner of its employment is very different from the practice in the United States. Time books, as we understand them here, are seldom, if ever kept, as the men are engaged by the day or shift and paid upon its termination. There are two systems in vogue, and in each the same idea of daily engagement and liquidation are carried out. Men working on *raya*, as day's pay is called, to distinguish it from contract work (which is let by the month or other stated time) are hired at the commencement of the shift by the shift-boss. All men and boys who wish to work on the shift assemble at the mine entrance and to those selected are issued candles, hammer, scraper and drills. The Mexican miner preparing to go on shift divests himself of his clothing, retaining only a breech-clout, a pair of crude leather sandals and his inseparable *sombrero* or sugar-loaf hat. These hats in shape all look alike to the 'gringo.' but to one accustomed to the country, the nativity of the wearer can be ascertained as the hat of every State has its distinguishing feature. Entering the mine, each man, or pair of men when working double-handed, is set so many holes to drill of such depth and in such direction as ordered by the boss. The amount of meters to be drilled varies correspondingly with the hardness of the rock and other conditions. In hard rock, shaft work, wet places and hot raises, less work is expected than in the more favorable parts of the mine.

Day Shift at Fortuna Mine, San Fernando, Durango, Mexico.

In the States of Sonora, Sinaloa and Durango, at most of the mines with which the writer is familiar, the miner's pay is 1½ pesos (Mexican dollars) per shift of nine to ten hours. To earn this, he must drill from a meter to a meter and a half according to the nature of the rock, and he is allowed as much or as little time as he pleases to do his shift. If he is a good workman and does his work quickly, he is permitted to idle the balance of his shift; he is seldom allowed to do more than his allotted task, but should he fall short of what was set for him to drill, he will be docked accordingly. Drills, as fast as dulled, are exchanged for sharp ones with the tool-boy who makes frequent rounds through the workings for this purpose. The drills are checked out to the tool-boy at the shop and he in turn exchanges with the miners, drill for drill; by this method the loss of drills through carlessness is obviated. About half an hour before the end of the shift, the boss makes his rounds and measures up the work of the drillers and at the same time gives them the powder necessary for each hole. The miners charge and fire the blasts and, on coming to the surface, they turn into the shop their hammers and drills. Muckers are also put to task-work whenever practicable, and trammers are given a stated number of cars to run out, the number varying according to the distance. Their pay is generally one peso per shift, in fact, this is the standard pay on the West Coast for all unskilled labor in Mexico, whether on the surface or underground. Timbermen, as a rule, earn more than the miners, and while they are hired from day to day, yet owing to the uncertain nature of their work, they are seldom put on piece-work.

Under the *boleta* (ticket) system of paying the men at the expiration of the shift, the boss pays each man by means of checks or tokens made of celluloid or brass, of which he has several denominations calling for 25c., 50c. and one peso each. The men turn these into the mine office and the value called for is punched in the proper place on a ticket which is subdivided into squares corresponding to the days of the month; the men retain this, and should they care to make any purchase at the company's store, they can do so by presenting their ticket. The amount of their purchase is punched out and at the end of the month any credits remaining are paid in cash. On the first of every month each man is given a *boleta* with his name written on it. This system has proved efficient in mines where a large number of men are employed. In smaller mines, the *memoria* is more in use; this is nothing more than a daily report to the company's store, showing the men's earnings for the day, so that credit for that amount may be given them. Under either system the men live so closely to their earnings that very few of them have any money coming at the end of the month. Company stores are profitable, as they earn from 100 to 500%. Owing to the fact that the Mexican miner can seldom be depended upon to work steadily, for he comes and goes as he pleases, this method of regulating their time seems to be best.

The accompanying illustration is that of the day-shift at the San Fernando mines in Durango, and includes miners, muckers, trammers, ore sorters, water-boys and tool-carriers. The children in the front rank are also workers performing minor duties which come within the range of their capabilities.

Aluminum Solder.

A solder has been invented whereby aluminum is easily soldered. It was discovered that by combining tin, zinc and aluminum with chloride of sodium in certain proportions a new composition is formed which has many valuable properties. In making the compound these elements are fused together in the proportion of twelve parts tin, two parts zinc, and one part aluminum. One per cent chloride sodium is added to this alloy. By varying these proportions somewhat the composition formed by them may be made harder or softer according to the various uses to which it is to be put. Sometimes a small amount of metallic antimony is added which increases its hardness without materially changing the nature of the composition.

The alloy is pure white color, and is capable of receiving a high polish, which will not tarnish. It may be molded, welded, and worked in many ways. One of the valuable uses claimed for it is that it will adhere strongly to many metals, to glass, and to other substances without the use of flux and without any special preparation of the surfaces to which it is to be applied.

It may be applied by an ordinary soldering-iron, but the use of copper for this purpose is not necessary.

This composition is particularly adapted to soldering aluminum, as it adheres to it strongly and is as readily applied to it as it is to other substances, such as copper and tin. Bars and wires of aluminum and other substances, may be welded together by its use. Its high conductivity and the fact that it is not subject to electrolytic disturbances make it of value in soldering or welding electrical conductors of copper or aluminum or other suitable material.

AN INTERESTING OCCURRENCE OF GOLD is described by Mr. A. E. Kitson, of the Victorian Geological Survey, in a report on the Evans Reward mine. The rock is described as gray grano diorite (granite), and the gold is distributed among its decomposed and disintegrating constituents, particularly in a strip from two feet to three feet wide. It occurs in small heavy pellets or irregularly shaped specks. This strip is between two fault plains, and the feature of special interest is the presence of the gold without association in any way with vein quartz. It appears to have been deposited by percolating waters. The origin of the gold cannot, however, be settled until the workings get deeper and into undecomposed rock. It is probable that lower down sulphides of iron and copper occur with the gold in mechanical association.—Queensland Government *Mining Journal.*

FLUORSPAR.—The uses of fluorspar in foundry work and in steel making have largely increased the demand for this mineral, but notwithstanding the increased demand there have been no new deposits opened during the last year or two, and Illinois and Kentucky still continue to be the chief sources of supply of this mineral. The principal mines are near Rosiclaire, Elizabethtown and Cave-in-Rock, small towns on the Ohio river.

Sinking a Shaft Through Water-Bearing Material.

In sinking the Auburn shaft of the Robert Gage Coal Co., at Bay City, Michigan, there was much difficulty caused by soft, water-bearing material; finally, after two attempts at shaft-sinking in the ordinary way had failed, steel-sheet piling was successfully employed. The *Engineering News* gives the particulars:

The sinking was commenced March 10, 1904, and the shaft was made 9 by 16 ft. in the clear. After going through about 50 ft. of clay, a bed of sand and gravel was encountered, producing a very large amount of water. Work was continued for about four months, using a steel shoe which was forced through the sand by 40 jack-screws, but when this had been sunk about 30 ft. into the bed of sand (and was still about 15 ft. from the underlying rock) the surface caved in around the shaft, owing to the pumps having removed large quantities of sand with the water. As a result of this caving, the timbers were broken and the shaft was thrown out of line, so that the work was abandoned. Two other attempts were made in the same neighborhood, but these resulted in similar failures. Mr. Charles Coryell, the general manager, estimates that about $75,000 were lost in these three unsuccessful attempts to sink the shaft through the bed of water bearing sand and gravel. There were sometimes as many as seven 6-in. streams of water coming from the sand, and it was found impossible to prevent the sand from coming in with the water and causing large voids behind the timbering.

The use of steel-sheet piling was then suggested, the special feature of the plan being that the piles would be driven through the treacherous material to solid bottom and a complete caisson formed before any excavation of this material was begun. It was decided, therefore, to make another attempt and to use the Friestedt interlocking steel piling. The fourth shaft was then started, being sunk in the usual way through the 50 ft. of surface clay and about 10 ft. into the sand bed. At this point the use of the steel piling was commenced, and the piles were driven to a depth of 20 ft. Each 20-ft. pile was made up of two 5-ft. pieces and one 10-ft. piece, the short lengths being used in order to get the pile-driving machine under the braces in the head-frame of the shaft. The 5-ft. and 10-ft. sections of adjacent piles broke joint with one another, and the joints in each pile were spliced with plates bolted on, a band of copper being fitted between the ends of the sections.

The splicing took but little time and did not retard the driving of the piles. Some boulders were encountered, but were either broken or driven out of the way with little difficulty. At the bottom the piles penetrated 18 or 20 in. into the slate rock, making a tight joint. When all the piles had been driven, so as to form a complete caisson, the excavation of the sand was commenced, the shaft being timbered as the work progressed. The shaft was 7 by 14 ft. clear inside the timbering, and after reaching the rock it was sunk through that in the usual way.

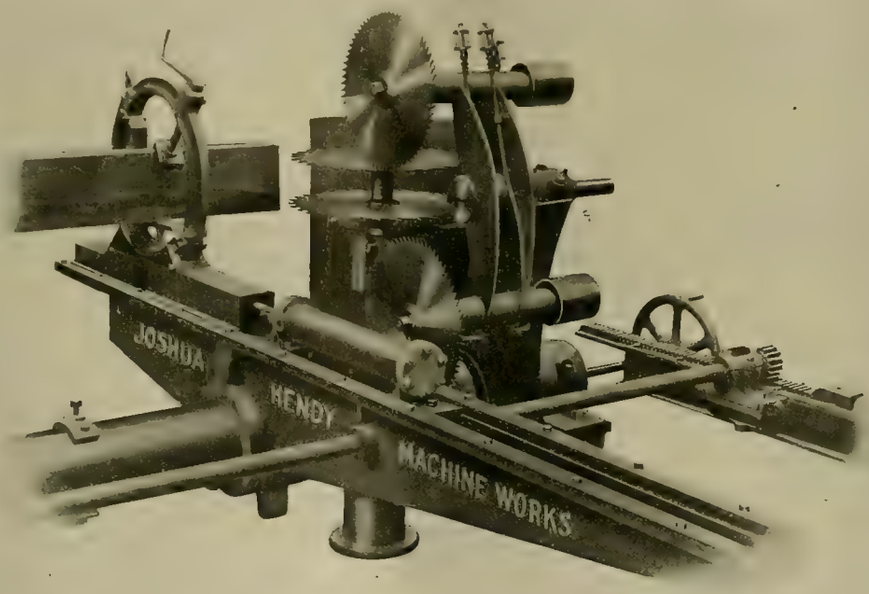
The method employed for driving the piles at the bottom of the excavated shaft is of special interest. At the surface and near the top of the shaft was a Star drilling machine, handling a 1,600-lb hammer by means of a jerk-line and giving it a drop of about three feet. The hammer was guided by a system of sheaves and guided directly over the piling by a large piece of pipe made of heavy sheet-steel. The use of a water jet to facilitate the work was tried at first, but this caused the sand to boil up in the shaft, and was abandoned. There was no trouble in driving the piles, but considerable time was consumed in changing the tackle to drive each piece.

It is estimated by an authority on copper that the largest individual consumer of copper in Europe is the German Electric Co., of Berlin, which uses about 18,000 tons annually, or about 40,000,000 lb. This is about the same amount with which the Westinghouse Co. is credited with consuming each year. The total visible supply of copper March 1, '06, was, according to Lewis & Sons, of Liverpool, 8,946 tons which is less than it had been for several years past.

An Improved Timber-Framing Machine.

The accompanying illustration shows a timber-framing machine of a type furnished to some of the largest mining companies of the West. The following description will make clear the construction and operation of this labor-saving machine, the purpose of which is to reduce the cost of framing either round or square timbers for mine use.

A heavy finished iron column forms the bed on which the various parts slide when it is desirable to change the length of the timbers. This column is held by cast-iron boxes and is prevented from turning by steel pins. The parts shown on the right are set and remain stationary except in changing the sizes of the tenon. Those on the left are connected by threaded rods and can be moved together by a screw inside the column, so as to shorten or lengthen the timber; they can be adjusted to suit the tenon desired and to line up the saws. The vertical saw-arbors are driven by quarter-turn belts from the counter-shaft and have a number of collars by which the saws can be set as desired. The horizontal arbors are mounted on a swinging frame, by adjusting which these saws are made to line up with those in front. The frame has also a side movement on its spindle, which is clamped by the cap-bolts. This change can be effected without altering the belt, as will be seen by tracing its course from the top of the driving-pulley to the upper-saw pulley, around the small pulley on the adjustable counter-shaft just behind the machine, to the lower-saw pulley and return to the driver.



A Timber-Framing Machine.

The various parts mounted on the column are prevented from turning by gibs, keys and set-screws, in addition to which the main frames are provided with jack-screws to stiffen them. The illustration shows the method of holding square timbers, but, by a quick change in the chuck-jaws, round timbers, also, from 8 to 18 in. diam., can be clamped. The chucks are made entirely of steel, and have teeth by which they are rotated 90° by an air-actuated rack and piston. The chuck and its cylinder are mounted on a slide, on the under side of which is a rack operated by a pinion on the long shaft that passes through the frames. This shaft can be rotated at will by means of the air-cylinder shown on the right.

With the saw in operation the timber is placed in the jaws, the chuck is closed and locked, the clamp-screws set down, and air is admitted to the large cylinder, causing the timber to pass through the saws. It is then returned, and air admitted to both small cylinders, causing the chucks to rotate 90°, when the second cut finishes the work. The valves controlling the admission and exhaust of air to and from the cylinders are placed in a position convenient to the operators. The question of lubrication of the rapidly revolving saw-arbors has been carefully worked out, each bearing having a sight-feed lubricator placed in plain view. All racks and pinions are steel and have cut teeth. Saw-guards are provided to cover the horizontal saws and end-gauge for setting the timbers.

The particular machine shown was made to work timbers from four to nine feet long between shoulders, 10 and 12 in. sq.; and round timbers from 8 to 18 in. diam., all of which sizes can be varied to suit the case.

The principal features of this machine have been thoroughly covered by patents secured by the Joshua Hendy Machine Works, San Francisco.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

Of the two samples from Lost Cabin, Wyo., one is limonite (iron oxide); the other, syenite.

The black heavy mineral from Leete, Nev., marked M. L., is magnetic iron oxide (magnetite).

Sample No. 1 from Douglas, Ariz., is gray copper. It also contains lead, zinc, and iron sulphide. No. 2 is micaceous hematite (specular iron ore).

The sample from Fortuna, Cal., is asbestos, of the kind that is usually ground for commercial uses, not having sufficient strength of fiber for weaving into asbestos cloth.

The mineral specimen from Cuyamaca, Cal., is tourmaline. The dike in which this mineral occurs should be developed with a view to ascertaining whether it contains gem stones of any description.

The sample from Gibbonsville, Idaho, marked T. M. O., is a metamorphic, semi-schistose rock, consisting mostly of quartz and fibrous hornblende. It is not a typical rock and cannot be distinguished by any particular name like granite, diorite, rhyolite, and similar specific terms.

Of the samples from Mayer, Ariz., marked J. C., the greenish rock is quartz, carrying chalcocite (copper glance), with malachite (green copper carbonate), as the result of the alteration of the glance. The dark colored rock is metamorphic—a tourmaline schist. There is considerable of this character of rock in Yavapai county.

Sample No. 1 from Kingman, Ariz., is volcanic ash, of no particular value. No. 2 is hematite. This may be from the gossan of a copper-bearing ledge, but this is difficult to determine. It is quite as likely to carry either gold or silver, and should be assayed for these metals. If copper be lower down in the vein, development will prove this later. It greatly resembles silver ore from the Silver King mine, at Calico, Cal., and also is similar to the gold ore of the Rose mine, east of Victorville, San Bernardino county, California.

A proper solution for removing scale and rust from iron would be one which removes the coating without attacking the underlying metal; but due to the fact that iron is attacked by all the known solutions more easily than the rather resisting scale, such a result is not likely to be attained. The action in pickling is due to the acid attacking the metal itself, and the scale is detached very largely because of the hydrogen formed, which quickly disengages it. The scale, when examined carefully, shows considerable porosity and cracks, which enable the acid to get in at many points; otherwise the disengaging of the scale would be very slow, and much metal would be consumed. Scale is either ferric oxide (Fe_2O_3), or ferro-ferric oxide (Fe_3O_4), the latter oxide, however, being the more important. A distinction may be made between two classes of baths: The dip, in which a practically concentrated acid is used, where it is desired to brighten the metal by the mere action upon the oxides, the concentrated acids not attacking the metal so readily; and the pickles, where diluted acids from about 3 to 20% in strength are used.

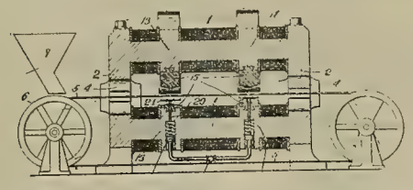
The Minerals of France.—The mineral production of France consists of lead, zinc, copper, coal and lignite, iron, antimony, arsenic and salt. An immense quantity of building stone and slate are quarried. The cement and phosphate production is large, aggregating sums far up in the millions of dollars. Coal is the chief mineral product. In 1904, 34,838,000 tons of coal and 634,000 tons of lignite were mined. The production of pig iron in 1904 amounted to 3,000,000 tons; wrought iron, 550,000 tons. The production of steel was as follows: Billets, 2,080,000 tons; rails, 246,000 tons; merchant steel, 937,000 tons; and plates, 299,000 tons. In 1903 there were 55 smelting works in activity, with 114 blast furnaces.

Mining and Metallurgical Patents.

PATENTS ISSUED MARCH 27, 1906.

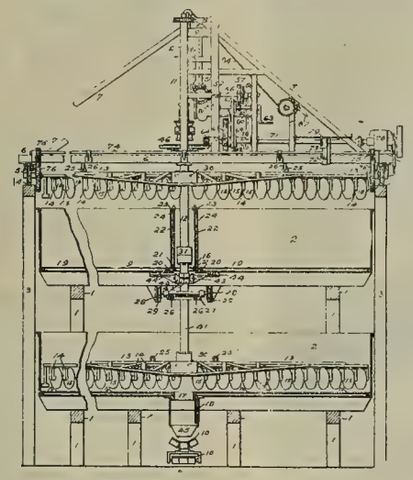
Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

MAGNETIC ORE SEPARATOR.—No. 816,491; R. R. Moffatt, Brooklyn, New York.



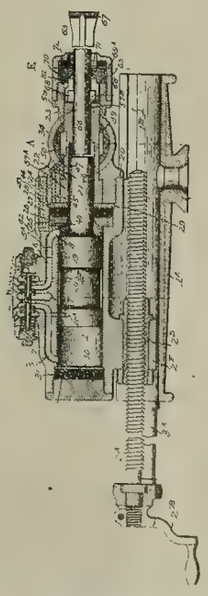
In magnetic ore separator, combination with a magnet comprising two sets of opposed poles producing two fields of different intensity, two cores each connecting one pole of one set in magnetic circuit with one pole of the other set, and side frames, having apertures, connecting the poles of the same set in magnetic circuit with each other, of a feed conveyer adapted to pass through the said apertures in the side frames, and two separating conveyers.

SYSTEM OF EXCAVATING AND FILLING VATS.—No. 816,065; H. W. Blaisdell, Los Angeles, California.



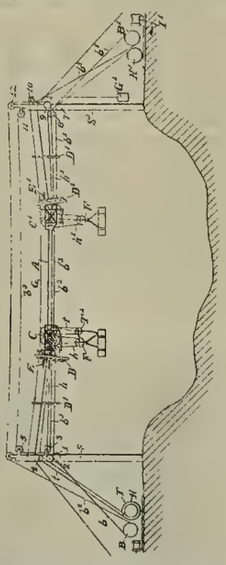
A system for discharging material from a plurality of rows of tiers of receptacles, provided with means for discharging material from the superimposed receptacle, a device constructed to receive the material discharged from superimposed receptacle and distribute the same uniformly within a subjoined receptacle and mechanism for alternately actuating means and for operating device.

DRILL-BIT-ROTATING MECHANISM FOR ROCK-DRILLING ENGINES.—No. 816,021; J. G. Leyner, Denver, Colorado.



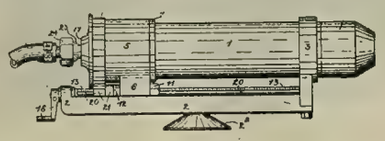
In a drill-bit rotating device for rock-drilling engines, suitable supporting casing, piston arranged to reciprocate in casing and containing an aperture, spring controlled pawls secured to piston in aperture, drill-bit holding chuck rotatably mounted in supporting casing and extending through the aperture in piston, ratchet teeth surrounding the periphery of drill-holding chuck and positioned thereon in operative relation to pawls, a rock-cutting drill-bit receiving aperture in drill-holding chuck, a drill-bit adapted to fit in chuck, means for attaching rock-cutting drill-bit to chuck and means for reciprocating piston and pawls to rotate step by step drill-holding chuck.

CONVEYING APPARATUS. — No. 815,963; C. H. Locher, Lemont, Illinois.



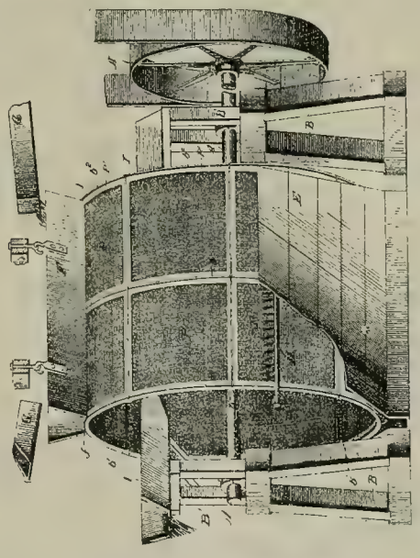
In cableway, in combination, single trackway, two carriages thereon, separate hoisting and traversing mechanisms for each carriage, hoisting-rope carrier for the hoisting rope of each of carriages and a single button-rope supporting the carriers of both hoisting-ropes.

ROCK-DRILL OR ROCK-DRILLING MACHINE. — No. 816,090; H. Hellman and L. C. Bayles, Johannesburg, Transvaal.



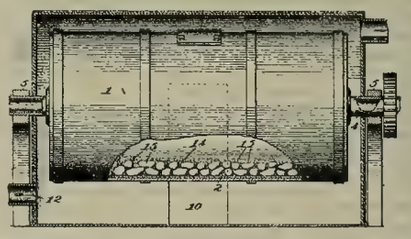
A rock-drilling machine or engine comprising in combination drill-cylinder carrying percussive apparatus, shell or cradle provided with forward guide in which cylinder is slidably mounted, a loose sleeve encircling cylinder constructed to slide in guideways formed in shell or cradle, feed-nut carried by sleeve, feed-screw stationarily carried by shell or cradle, and means for rotating the screw to traverse the sleeve and with it the cylinder longitudinally of the shell or cradle.

REVOLVING DRUM SCREEN —No. 816,426; J. P. Brew and E. P. Suiter, Basin, Montana.



A revolving screen comprising central shaft, a drum having peripheral covering of screen material and open ends, central supporting frame connecting shaft to drum and consisting of a central spider with radial arms rigidly attached to shaft and having adjustable spoke ends, an external hopper placed above the drum for feeding the material on the outer surface of the same and two reversely inclined discharge troughs arranged in the drum and extending from the center outwardly and downwardly through the open ends of the same and external supports for these discharge troughs.

PROCESS OF TREATING ORES.—No. 816,061; C. E. Baker and A. W. Burwell, Cleveland, Ohio.

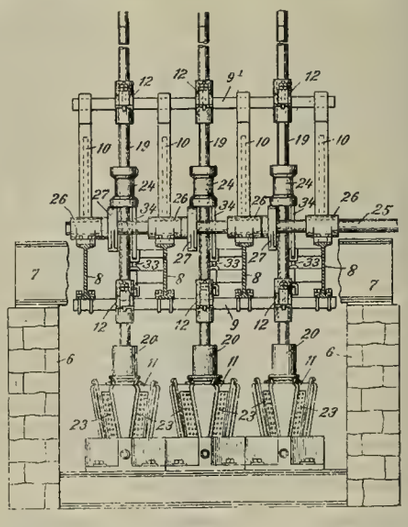


The process which consists in reacting with chlorine on a pulverulent ore containing metal or metals and a metalloid, producing the chloride of the metal or metals of the ore and recovering the metalloid in elemental state.

AMALGAMATOR.—No. 816,243; W. H. Morgan, Los Angeles, California.

An amalgamator comprising an inclined sluice box provided with an amalgamated surface and having depressions forming riffles sunk in the bottom and spaced apart and charged with mercury; the upper walls of riffles respectively being overhanging and deeper than the lower walls, and a screen arranged to shield the amalgamated surface.

STAMP-MILL.—No. 815,936; M. P. Boss, San Francisco, California.



In stamp-mill, the combination of longitudinal girder, supporting pillars therefor, situated entirely independent of the mortar boxes of mill, a series of parallel sills connected at one end to girder, means for supporting the opposite end of sills, guide girths connecting sills, guides on guide girths, series of mortar boxes arranged in a line, series of stamps movable in guides, and means mounted on sills for reciprocating the stamps.

Special Correspondence.

LONDON, March 28.

The Spassky Copper Mine, Ltd., was formed in 1904 with a nominal capital of £300,000 in £1 shares, of which 250,000 are issued, and £102,400 of 5% debentures. There is a board in Paris, as well as one in London. The property, which was purchased for £200,000 in fully paid shares and £100,000 in cash, comprises the Spassky smelting works and copper mines, the Yuspenssky copper mines and the Karagandy coal mines, all in the Akmolinsk district, Siberia. The nearest station on the Siberian railway is Petropawlowsk, 500 miles distant along a post road, yet the cost of freight on copper from the mine to the railway is only about £5 per ton, the sleighs in winter and carriages in summer traveling at the rate of 100 miles per day. At the first annual meeting last week the chairman, Mr. Arthur Fell, stated that the district yielded iron, fireclay and other minerals, and that plentiful supplies of wheat, meat, etc., can be obtained at extraordinarily cheap prices. A report on the Yuspenssky mine has been received from Mr. E. T. McCarthy. From this it appears that the mine, as opened up by the former owners and dealt with by the company, consists of two shoots, one known as the Vladimir and the other as the Annensky; the two shoots are believed to join. When the company originally took the property over, the Annensky shaft was down 258 to 280 ft.; this shaft was sunk to the 350-ft. level, and the drift from the shaft to the orebody was extended. For the first 36 in. it ran 40% copper; then it went through 20 ft. of 20% ore, and then 51 ft. further still ore that assayed copper, and faded down to 1% at the extreme further 8% side. This body of ore has now been opened up to a large extent, and from it, above that level, Mr. McCarthy estimates the company should extract 38,000 tons, beside sundry small amounts which are in the level above. That, the chairman pointed out, is in the Annensky. The Vladimir shoot is only 200 ft. off; according to Mr. McCarthy's report, this contains 21,000 tons of ore, as far as opened up. He also estimates that the ore-shoot may reasonably be held to continue 100 ft. below, because at the bottom there is a splendid floor, part of it almost half copper, and the other part about a quarter copper. He expects this will go down another 100 ft. and estimates a further 116,000 tons. The amount of copper in the 100 ft. and in the 75 ft. down to this drift amounts to 13,000 tons in one part and 24,000 tons in the other, and the value of this copper he puts at £3,374,000, that is, taking copper at the price of £90 per long ton. The chairman said that at the present price of copper, the figures of Mr. McCarthy would have to be increased by £749,000, which would make the total amount £4,125,000; in addition to the ore already proved, he says we may believe that the enrichment, through leaching, will continue down to 600 ft., and then the workings will get into the normal condition of this ore, which, although not so rich, must pay handsomely.

Other deposits are referred to in Mr. McCarthy's report — as shown by the old workings — which cannot at present be valued, and there are also outcrops on other parts of the property, impregnated throughout with blue and green carbonates. The smelting works are at Spassky, 72 miles distant from the Yuspenssky mine. These works were originally placed there by the former owners for two reasons: (1) Because there was a good water supply, and (2) because there were large copper mines actually within 100 yards of the works. The report states that there are 25 claims or mines round the Spassky smelting works, but it is impossible for the company to undertake the opening up, prospecting and deepening of these other mines while they have so much work in hand. That will have to be left for the future and, possibly, to subsidiary companies.

At the coal property, 20 miles from the smelting works, the manager has reported the cutting of two seams, one 60 in. and the other 55 in. thick. This coal has been in use, and by it all the copper produced by the company during the last 18 months has been smelted. Up to the present the output of copper has been limited to 100 tons per month from the old works, but the modern plant is now being erected to produce 300 tons per month or more. For the period covered by the first accounts—15 months—the profit, using the old works, amounted to £33,000. After writing off preliminary expenses, cost of the debenture issue and development work, there is a carry forward of £17,000. A cool observer is bound to assume that it is only in anticipation of the good things to come that the £1 shares have been talked up to £7 15s. in the market.

A still newer claimant for favor is the Phillips River Gold & Copper Co., Ltd., started in January last with a capital of £100,000 in shares of £1 each. The property is in Western Australia. According to the information given at the statutory meeting, the amounts called up have provided £37,500, out of which some £26,700 has been remitted to Australia for the purchase of leases and options, and for working expenses; £720 has been paid in London for the formation expenses, etc., and there is £10,080 cash on hand. The chairman pointed out that no intermediate profits have been made on the purchase of any of the properties and options; and that no bonus shares have been issued or provided for, nor has any money been paid, nor is there any money to be paid, for underwriting. Some three years ago the possibilities of the Phillips River district attracted attention, and the discoveries made by prospectors were carefully watched by the directors and their agents in Western Australia. Toward the latter part of last year the field had been so well prospected and the developments so promising that in September options were secured on eleven leases. Mr. Fred Morgan was then appointed manager and commissioned to make a more thorough examination. Options on five of the leases were abandoned, three leases were purchased, and the options on three others are still running. The total area purchased and under option is 247 acres. Recent developments confirm the manager's previous report and the favorable opinion of Mr. Montgomery, the Western Australian State mining engineer. Mr. Charles Kaufman, the chairman, in concluding his speech, said that in the whole of his long experience in mining, after three years carefully watching the developments and the advantages of the Phillips River district and the more recent developments on the company's properties, it was his opinion that the company possesses the possibilities of great mines.

The prospectus has been advertised of New Junction Deep Leads, Ltd., capital £80,000, in shares of 5s. each. Two of the directors are on the boards of other deep leads in the same district. The company has been formed under the auspices of the West Australian Goldfields, Ltd., to acquire the whole of the undertakings of the Junction Deep Leads of Victoria, Ltd. The property to be acquired adjoins the Charlotte Plains Consolidated Gold Mines, Ltd., and the Victorian Deep Leads, Ltd. The Charlotte Plains company has now unwatered its property sufficiently to enable trial washings of the gravel to be made, with satisfactory results, while at the Victorian Deep Leads the pressure of water is decreasing; consequently, it is believed by local advisers and engineers that these pumping operations will have had a considerable effect in reducing the pressure of water that will be encountered on the Junction property. The main drift or tunnel is now in a distance of 700 ft., and it is estimated that an additional 600 ft. will bring it under the wash dirt.

Near the junction of the two gold-bearing leads, and on the property to be acquired, a shaft has been sunk to a depth of 325 ft., at the bottom of which a pump-chamber has been cut into solid rock, 45 ft. long, 25 ft. wide and 20 ft. high, which contains a three-throw plunger pump with a capacity of 2,500,000 gal. a day. This pump will be driven by a 250-h.p. electric motor, the power being supplied by the Deep Leads Electric Transmission Co. This power company has a capital of £45,000 (all of which is invested in plant). Its central station is believed to be one of the finest in Australia.

According to the latest cabled news from the Charlotte Plains, the result of treating 189 fm., taken from the drifts put in to drain the wash dirt, was 119 oz. 6 dwt. of gold; a patch of black sand has been struck, which assays up to 30 oz. per fathom.

The estimated profit of Esperanza (Mexico) reported for the month of February is $378,919, an increase on January, but not up to December amount. The market has shown disappointment in the rate of the dividend declared for the quarter to March 31 — six pence per share, with an addition of 5s. per share, instead of the extra 10s. paid for December quarter. After falling to £3 15s. the shares have recovered to £4, but anxious enquirers on this side fail to elicit the cause of the lower dividend.

Camp Bird must be considered to have beaten the record for a rapid succession of lurid catastrophes—first the snowslide, then the devouring fire. The market has begun to recover from the shock, helped by the assumption that there is nothing to prevent development at the mine being continued, for which and the reconstruction of the mill, etc., ample funds are available. Meantime dealers and speculators have had the chance of a turn in the shares.

JOHANNESBURG, March 12.

Like a thermometer, the Rand has its ups and downs. For a while we were on the mountain tops, for it seemed as if the chief difficulty, that of labor, had been solved. Now we are down in the valleys. There is a bigger outbreak of 'dumps' on the Rand today than has existed for years. Not that the pay of the wage-earner has been reduced, or that cost of living has suddenly doubled. The condition of the employed is, for the present, quite satisfactory. It is the outlook on the future and the number of unemployed in our midst which gives most people the 'blues.'

The Rand Aid Association has issued a circular, a report of which in the press is headed, "Don't come here!" The number of men of all trades and professions, who have applied to the organization for work, has greatly increased during the past month. Many artisans have been employed in the construction of large buildings in Johannesburg. The Carlton Hotel (the finest hotel in South Africa) is now finished, as are the Cullenan Buildings, the Johannesburg Consolidated Investment Buildings, etc. As there are no new buildings going up, these skilled artisans are now out of employment. Commercial houses have found it necessary to curtail expenses and have dismissed many clerks. The neighboring colonies seem to consider the Rand a Mecca, and many workers from other parts of Africa have come to Johannesburg. The number of 'wasters' in the ranks of the unemployed is large. These men make off to the nearest bar with their first pay. But unfortunately there is a number of capable, respectable men, only too eager to work, who cannot find employment. The demand for relief has considerably increased. And yet there is a paradox in this question of unemployed. While the press has been pointing out how many idle men there are in our midst, quite a discussion has gone on over the scarcity of really skilled miners on the Rand. It is highly improbable that there are many first-class miners, with local experience, in the ranks of the unemployed today. The only real demand seems to be for skilled miners and rock-drill men. Of course, there are hundreds of so-called miners looking for work.

Much the same state of affairs prevailing today was noted in 1897. The explanation is simple. The Transvaal has actually one industry. If men are discharged from mines, there is practically no other sphere for them to enter. Curtailment of expenses on a few properties, and the closing down of a mine or two, soon creates a problem of the unemployed. So th Africa's power for absorbing white labor is extremely limited. While realizing the futility of making this a 'white man's country,' like Australia, one cannot help sympathizing with those enthusiasts who have tried to increase the opening for white labor, by advocating it for the rough work now done by Chinese. The explanation for the depression is not to be found in the collapse of the Rand. Potentially the Rand is as great as ever. Recent exploratory work has enormously extended the horizons. The trouble is almost solely political. Provided the political difficulties can be overcome, and an ample supply of unskilled laborers is provided, the Rand will leap forward once more. But the Liberal party in England has upset all the arrangements made for the supply of unskilled labor from China. Nobody knows exactly where we stand, or what is going to happen. Expansion at the present moment, with so much uncertainty, is out of the question.

SALT LAKE CITY, April 9.

Ground has actually been broken for the new concentrating mill to go up near the townsite of Garfield, under the direction of the management of the Boston Consolidated Mining Co. Contracts for the structural material and equipment for the mill and power-house will soon follow. There will be a great deal of interest attached to the building of this plant, and that of the Utah Copper Co. near by, as millmen and metallurgists will have excellent opportunity to observe what stamps will do in ore crushing as compared with rolls and Chilean mills. Identical ores are to be treated; but the metallurgists of the respective companies differed as to methods. The staff of Samuel Newhouse, for the Boston Consolidated, decided in favor of stamps, and the Utah Copper's management is an adherent of the roll and Chilean mill. The result will be watched with interest, and doubtless a gain in knowledge.

The board of directors of the Jefferson Consolidated Mining Co. has commenced suit against the former president of the company to compel him to return to the treasury of the company 50,000 shares, in accordance with a certain agreement alleged to be in existence. Schmittroth owns 240,000 shares and the court is asked to restrain him from disposing of any portion of it until the case is settled. The company owns property near the mouth of Little Cottonwood cañon.

The mill at the Overland gold mine at Sunshine, Tooele county, will be started in about 60 days. It has reserve-bin capacity of 150 tons and tank capacity of 2,000 tons. For nearly a year the company has directed its energies toward sinking a new vertical working shaft, the old incline having caved and left it unfit for further use. The new shaft is down over 900 ft., entering the orebody at 860 ft. The ore at this depth carries values slightly better than was disclosed in the workings nearer the surface. The average is close to $3.50 in gold. E. W. Clark, Ophir, Utah, is manager.

The Columbus Extension Mining Co. has been organized to operate the Jacobson group of lode claims at Alta. The stock has all been subscribed. The company will start off with about $200,000 available for development and equipment. The property adjoins that of the Columbus Consolidated and Consolidated Flagstaff companies. A. Jacobson is president; A. O. Jacobson, vice-president; S. A. Whitney, secretary and treasurer, all of Salt Lake City.

There has again been delay in starting the new Godiva mill at Eureka, owing to the failure of certain parts of the equipment to arrive, which is now being installed. The plant will be running, however, before the close of the month.

Increasing interest is being taken in development work in the north Tintic district, near Eureka. The Selma group has been incorporated. The officers and directors are: Lars C. Peterson, Judge Thomas Marioneaux, of Salt Lake; Dr. A. L. Castleman, Bingham; E. K. Olson M. E., and Culbert Olson, of Salt Lake City.

Better results are being obtained from the operation of the concentrating mill of the Newhouse Mines & Smelters corporation, which is situated in Beaver county. The ores of the Cactus mine are treated at this plant and the record for the last week in March showed an average of a little more than 12% copper in the concentrate produced, whereas, about the beginning of the year, the returns were 8 to 9%. President Newhouse says about 75 lb. of concentrate are being shipped daily, representing the returns from 700 tons of ore treated. Within a few weeks the mill will treat 1,000 tons daily. It will probably be two months yet before the work of stripping the two acres of surface is completed and the commencement of mining by steam shovel begins, when the bulk of the ore going to the mill will come from this source, when, according to Mr. Newhouse, the cost of mining will be reduced from $1.50 to 40c. per ton. Economic methods have resulted in reducing the milling costs from 75c. to about 47c. per ton and the management expects to bring it down to 35c. The mill is saving about 85% of the values.

Engineers in the employ of the American Smelting & Refining Co. are making an examination of the Mammoth mine in Tintic district.

The directors of the Uncle Sam Consolidated Mining Co. have declared a dividend for April of $5,000.

With 80 acres of ground, adjoining the Albion mine at Alta, the Secret Mining Co. has been organized and will begin development. The officers are: W. M. Minor, New York, president; Charles P. Minor, Kansas City, vice-president; H. S. Harper, Salt Lake, City secretary.

An order was placed during the week for 18 Chilean mills to do service in the new mill of the Utah Copper Co. at Garfield. Another order covering the steel structural material, to weigh about 2,000 tons, for the second unit has been let to the Minneapolis Steel & Machinery Co. Excavations for the second unit are being made and are to be finished and foundations in by August 1.

It is expected that the announcement will soon be made officially that F. Augustus Heinze and associates are in control of the Bingham Consolidated Mining & Smelting company.

Developments at the Daly Judge mine at Park City are growing more important daily. A large orebody has been opened on the 1500-ft. level. Driving both ways on the shoot is in progress and it has been opened for over 200 ft. The width has not yet been ascertained, but is known to be at least 10 feet.

High-grade ore struck on the 700-ft. level of the New York Bonanza mine, at Park City, has created new interest in that property. The ore is about three feet wide.

Eastern parties are having the Utahna mine, in the Errickson district, examined with a view to purchase.

Development at the Kennebec mine, in the Big Cot-

tonwood district, has been resumed. A contract to drive the intermediate tunnel 300 ft. further has been let.

Sinking below the 900-ft. level of the Scottish Chief mine, near Park City, is about to begin.

Recent rains in the south practically destroyed about 15 miles of the 40-mile road built last year by the Utah & Eastern Copper Co. The road runs between the mine and smelter and Acoma, a station on the main line of the San Pedro, Los Angeles & Salt Lake railroad.

The owners of the Jenny and Utahna mines at Fay, Nev., have decided to put in a 30-ton mill. Charles A. Short, of Fay, is manager.

The Southport Mining Co. has been organized to work at Stockton, where 100 acres, adjoining the Honerine and Cyclone properties, form the basis of operations. The incorporators and officers are the following: J. R. Rand, of the Ingersoll-Rand Drill Co., New York, president; W. C. Alexander, manager of the Black Diamond Mining Co., Salt Lake, vice-president; L. H. Farnsworth, cashier Walker Bros.' bank, Salt Lake, secretary and treasurer, who, with Charles H. Scheu, of Salt Lake, and William E. Beach, Lafayette, Indiana, are directors.

What appears to be the most important strike of ore ever made in the Eagle & Blue Bell mine of Tintic has been made on the 1,000-ft. level of that property. Nothing official as to the extent of the find has been given out.

The total shipments from Park City mines last week amounted to 4,094,860 pounds, the shippers and amounts being: Silver King, 1,617,860; Daly West, 1,400,000; Little Bell, 115,000; Daly-Judge, 773,000; Daly-Judge (zinc middlings), 194,000.

The ore and bullion settlements reported by Salt Lake banks last week aggregated $407,800.

Ore shipments from the Tintic mining district last week aggregated 153 carloads, the shippers and amounts being: Ajax, 2; Black Jack, 1; Beck Tunnel, 3; Bullion Beck, 11; Centennial Eureka, 50; Dragon Iron, 2; Carisa, 1; Eagle & Blue Bell, 6; Eureka Hill, 6; Gemini, 22; Grand Central, 8; Joe Bowers, 1; Lo. Mammoth, 5; Mammoth, 15; May Day, 4; Ridge & Valley, 4; Swansea, 2; United Sunbeam, 1; Uncle Sam, 2; Victoria, 6.

BUTTE, April 7.

The March copper output of the Butte district amounted to 29,347,080 lb. The intensely cold weather which continued for two weeks was responsible for a shortage of 3,000,000 to 4,000,000 lb., as many of the mines were handicapped and a number of them had to suspend operations altogether for several days. Except for several days, the Gagnon mines of the Amalgamated Co. hoisted no ore throughout the month. The daily output of ore in tons, the yield per ton in copper, and the total daily yield of pounds in copper are shown in the following table:

Company.	Tons of ore.	Pounds per ton.	Total lb. daily.
Boston & Montana Co.	3,550	68	241,400
Anaconda	3,300	68	224,400
Butte & Boston	500	60	30,000
Washoe	460	63	28,980
Parrot	550	68	37,400
North Butte	1,100	120	132,000
Butte Coalition	1,600	70	112,000
Clark's Original	800	80	64,000
Pittsburg	200	80	16,000
East Butte lessees	200	100	20,000
Raven	50	110	5 500
Miscellaneous	500	70	35,000
Total	12 810	...	946,680

The following table shows the total ore tonnage and total copper output in pounds:

Company.	Tons of ore.	Pounds of copper.
Boston & Montana	110,050	7,483,400
Anaconda	102,300	6,956,400
Butte & Boston	15,500	930,000
Washoe	14,260	898,380
Parrot	17,050	1,159,400
North Butte	34,100	4,092,000
Butte Coalition	49,600	3,472,000
Clark's Original	24,800	1,984,000
Pittsburg	6,200	496,000
East Butte lessees	6,200	620,000
Raven	1,550	170,500
Miscellaneous	15,500	1,085,000
Total	397,110	29,347,080

The stockholders of the old Butte Mining & Development Co., of whom there is a very large number, will be interested in the announcement that the Butte Copper & Zinc Co., which has purchased the Emma mine on which the former company had a lease and option, is about to resume operations on that property and will build a plant at the mine for the reduction of the large deposits of zinciferous ore, for both zinc and silver. The new company will use the new process which is employed by the Montana Zinc Co., said to be the only process that has been found to successfully treat the Butte ores of that character. The Butte Mining & Development Co. spent about $200,000 in sinking the Emma shaft to a depth of 800 ft. and in crosscutting. Because there was too much zinc in the ore—zinc then being regarded as a detriment and smelters charging a large penalty for treating such ore—the company abandoned the property and relinquished the option. Dr. Maurice Eisenberg secured an extension of the option through the old company and then interested new capital in it, and after devoting three years to it succeeded in reorganizing under the name of the Butte Copper & Zinc Co. Clarence B. Wisner, of New York, owner of the new zinc smelting process, is interested with Dr. Eisenberg. The stockholders of the Butte Mining & Development Co. were given a chance to come into the new company, but only a few took advantage of it. The new company is capitalized as the old one was, for $2,500,000. The company has ordered machinery for an electric smelting and hoisting plant at the Emma and announce that within six months it will be hoisting and treating the Emma ore. The shaft is to be sunk to a depth of 1,600 ft., at which depth it is thought the copper zone will be struck. The company has also acquired several adjoining claims, one of which in past years was worked extensively for silver and was in good ore when further work was made unprofitable by the low price of silver. The plans of the company include the unwatering of the shaft and 2,000 ft. of underground workings; drifting on the orebodies on the 400, 500 and 800-ft. levels, to place the mine in condition to produce about 300 tons of ore per day; sinking the shaft to a depth of 1,600 ft. and crosscutting to the vein at the 1,200 and 1,600. The promoters of the company believe that the zinc will practically disappear at a depth of 1,200 ft., but so far as its zinc smelter will be concerned there will never be a lack of ore in the Butte district, because there is a zinc capping of 500 to 1,000 ft. nearly all over the district, and while heretofore the zinc contents of the ore has been a detriment and a loss and extra expense in the treatment of the ores, it will now become a valuable asset. Mr. Wisner and his associates have for several years experimented with the process and have demonstrated its success by working the ores of the Alice and Lexington mines. For a year a little experimental plant at the Alice mine has been handling about 100 tons a day, part of which came from the Lexington.

The Raven has driven 30 ft. east on the north vein of the Snoozer, from the crosscut on the 1,500-ft. level, and crosscut into the hanging wall, showing the vein at that point to be 20 ft. wide. The ore through the entire width of the vein is good shipping ore. In the distance of 30 ft. the vein has widened from 12 to 20 ft. On the 1,200-ft. level the east raise is also in ore, four feet wide and running about 12% copper. This raise is 600 ft. east of the crosscut. Another raise from the east drift is in good ore, and so are two raises from the west drift. Drifting is still in progress on the south vein of the 1,200 level, and there are now 300 ft. between the two faces of the drifts of ore two to six feet wide. It is all good shipping ore that yields four to six per cent copper and carries silver.

The Butte & St. Louis Mining Co. has commenced to operate on a small scale at the Kessler property in North Walkerville. A hoisting plant is being installed, and sinking on the shaft from the present depth of 100 ft. to to the 300 level will shortly be commenced. The property is under the management of S. M. Roberts, while active operations will be under the direction of Thomas R. Davey. The Kessler some years ago produced large quantities of pay ore, which was mined from the 150 level of the old shaft. Connections from the old to the new shaft have been made, and in addition to sinking the new shaft deeper the company expects to mine ore at once from the old workings. There is a good showing in the mine at the 100-ft. level, a stope 90 ft. long being blocked out. The ledge extends the full length of the Kessler claim.

The Butte Copper Belt Mining Co., capitalized for $7,500,000, has been organized in Butte for the purpose of prospecting and developing an extensive tract of mineral land east of Butte on the continental divide. The company controls about 200 acres, undeveloped. The plan of the new company is to sink three shafts and thoroughly explore it. The officers of the company are James A. Talbott, president; Samuel H. Treloar, vice-president; J. R. E. Sievers, treasurer; Russell P. Howard, secretary; A. J. Poser, manager.

The Anaconda Co. has started to sink the shaft of the High Ore mine 600 ft. deeper. It is now down to 2,200 ft., and is one of the deepest shafts in the district. The High Ore shaft and workings of that mine have been so constructed as to act as a drain for nearly all of the hill mines of the amalgamated company. Steel structural work for an electric plant is also being put up at the High Ore. The plant will receive its power from the Missouri river, about 75 miles from Butte.

F. A. Heinze, who recently returned to Butte from New York, says he will devote his time to mining in Montana and elsewhere in the West, notwithstanding the fact that he sold all of his United Copper interests to the Butte Coalition company, and that in a short time he will be employing as many men as he did before.

TORONTO, April 7.

The Ontario Government this week announced an entirely new departure in connection with its mining policy. As previously intimated, a question of much interest has been the disposal of the particular tract of valuable mineral land lying south of the Cobalt mining area, known as the Gillies timber limit, which has been closed to prospectors in order to allow of the removal of the timber. The situation is peculiar, owing to the known existence of valuable deposits, all claims for priority of discovery being doubtful and confusing. On April 3 Premier Whitney announced in the Legislature that the Government, after considering all the circumstances, had arrived at the conclusion not to dispose of it at all, but to retain title and develop and mine it for the benefit of the people of the Province. As soon as the time set for the removal of the timber expires, which will be on October 1, the limit will be placed in the hands of a commission to operate for the public revenue.

The limit in all embraces about 100 sq. mi., of which the extreme northern portion (which projects into the Cobalt mining area to within half a mile of the town and has an area of some 3½ sq. mi.), is known to be very rich in silver-cobalt ore. In places solid masses several pounds in weight of almost pure silver have been found on the surface and much of it has been carried off. At present it is guarded by a strong force of constables. It is not positively known whether the remainder of the limit has any valuable deposits or not, though it is reported to show indications of mineral wealth. The Government has instructed W. G. Miller, provincial geologist, to make a thorough examination this season of the portion of the limit near Cobalt and ascertain the geological formation and the course of the veins, for the guidance of the Commission in the course of the development. At a later date he will make an exploration of the other portion of the tract.

A general inspection of mining locations in the Temiskaming district will be made as soon as the season permits, by A. H. A. Robinson, recently appointed mining inspector, which may result in throwing open many of the locations lately made. Many claims are held by prospectors, who have staked out locations during the winter when it was practically impossible to make discoveries of mineral, and in such cases their claims will be disallowed.

Mining Summary.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

ARIZONA.

Gila County.

(Special Correspondence.)—Ore hauling from the mines at Globe, which was interrupted for a few days this and last week by the heavy rainfall, has been resumed, although the roads in places are still soft. Two outfits are reported bogged, one on Miami flat and the other some distance west of that point. There are now more teams hauling ore to the Old Dominion smelter than at any time heretofore. Forty teams are hauling from the Live Oak mine, the Gibson Mining Co. has 17 teams, and there are 8 or 10 hauling from the Black Warrior, Geneva, and other mines. The Old Dominion is now in much better shape than it has been at any time since the fire in the Interloper shaft, on February 20. Nearly the full complement of men is at work in the mine and all the levels have been opened. Shaft work is progressing rapidly, and the winze sunk from the tunnel in the lime quarry will be completed to the third level within a few days, which is expected to create a strong down draught and to improve ventilation. The C shaft has reached a depth of 80 ft. and is going down four or five feet daily. At the smelter three furnaces have been running most of the time and the production of copper for the current month will be 2,750,000 lb. The new furnace will be completed by the end of the week.

Globe, April 8.

Mohave County.

(Special Correspondence).—The shaft of the West Gold Roads Co. is down 350 ft. and will be continued to 500 ft., where a crosscut will be run in expectation of reaching the pay-shoot of the Gold Roads mine, which is but 300 ft. away. There is much activity throughout the district. The postoffice for Gold Roads section is now officially known as Gold Roads, not Acme, as formerly.

Gold Roads, April 8.

(Special Correspondence.)—A report has reached Kingman to the effect that a discovery of rich placer ground has been made in the Cedar basin country, to the north of Rioville. The gravel is said to be extensive and the gold coarse. Many people are rushing in there. The Cedar basin is on the east side of the Virgin range, north of the Colorado river. Last year some good veins were discovered and worked. The ore was found to be gold-bearing, oxidized iron. Harry Gentry, of St. Thomas, and M. Redman, of Kingman, were interested in mines in that section. Mr. Gentry at one time had his properties under bond, but the parties failed to take the option, owing to the lack of water and its isolation. The veins showed a good grade of ore, which is easily worked. Now that placer gold has been found there, means will probably be found to work them.

Arrangements are being made for the purchase and erection of a concentration mill on its Vanderbilt mine at Cerbat by the Cerbat Mountain Mining Co., of which John Boyle is general manager. The mill will have a capacity of 25 tons per day. The ore now being taken from the lower level will be shipped to the smelter. Ore from the upper levels will be milled, the concentrate calcined and amalgamated. In this way a saving will be made in freight charges. The mine is proving one of the best properties in the district.

Thomas E. Ludlam, of Sea Isle City, New Jersey, who arrived in Kingman recently, has gone to the Mocking Bird mine in Minnesota district, of which he is general manager. The Mocking Bird, under recent development, has exposed six feet of ore which assays more than $300 gold per ton. A force of men has been developing water the past two months, with success. Two carloads of ore are to be shipped to the smelter and milling tests are to be made.

Kingman, April 9.

It is reported from southwestern Utah, one of the wildest spots in the West, that placer fields have been discovered in what is known as Cedar basin. The mines are north of Iceberg cañon, one of the tributary cañons of the Colorado, and on the east side of Virgin mountains. Last summer rich veins of gold were found there, but lack of water made it impossible to work them. The placers are reported to be rich in coarse gold and the field extensive. A rush from St. George, Utah, and the Muddy valley, in Nevada, is now on, and many people are outfitting and will go into this latest Eldorado.

Yavapai County.

(Special Correspondence.)—The mill on the properties of the Arizona Gold Lodes Co. is running steadily on ore from the mine in Cherry creek district. The main working shaft is down over 200 ft. and in good ore.

Briggs, April 8.

CALIFORNIA.

Butte County.

In the development of the Sunset mine, in Nimshew district, two miles north of Nimshew, a copper-bearing ledge 50 ft. wide has been cut, some of the ore being high grade. The mine is owned by M. C. Torrison, who became interested in the Indian Springs gravel mine some years ago, and spent considerable money in an endeavor to re-discover the channel, which had been lost by former workers. The Indian Springs was at one time one of the biggest gold producers on the Nimshew ridge. There are two or three miles of underground development on the property.

Calaveras County.

Frank Bernardi, of Mokelumne Hill, has bonded the Deep Gulch, Gold Standard and Steep Gulch mines for two and a half years for $50,000. The mines are just north of town, in a district which has not been worked to any great extent. Eastern capital is interested and work will commence May 1, when 15 men will be employed.——Work on the Nuner tunnel is making good

progress, with a full force of three shifts of eight hours each.——Work on the Ariel mine has been started up by Frank Cortmarsh.——The repairing and retimbering of the tunnel at the North Star is progressing. Other mines in the district will resume as soon as the weather appears to be settled.

Inyo County.

A smelter is being built near Keeler to treat the ores of the Cerro Gordo mines, which were extensively operated in the later 70s. At that time a smelter was in blast at Cerro Gordo, but the old works were dismantled years ago. During the 80s some sorted ore was shipped from Cerro Gordo to Selby's, but of late years there has been little activity in the old lead camp.

Nevada County.

The annual report of the North Star Mines Co., of Grass Valley, shows that during the year 1905 the total output of ore was 77,530 tons, yielding $11.30 per ton, costing $4.92 per ton for operation and $1.30 per ton for development work; a total of $6.22 per ton, leaving a profit of $5.08 per ton. This is without allowance for improvement outlays, which amounted in 1905 to about $1.28 per ton of ore. The total value of the ore produced was $876,361.31, at a current operating cost of $381,313.73 and an operating profit of $495,047.58. During the same period sums amounting to $207,750.19 were expended on other accounts, mainly for development and improvement.

Shasta County.

(Special Correspondence).—The managing director of the Mammoth Copper Mining Co., A. F. Holden, has completed an inspection of mine and smelter, and is so well satisfied with the results already obtained that he has decided to install two more blast furnaces, making a total of five; also, mechanical roasters and a reverberatory furnace to treat the fines and flue-dust. The company's smelter superintendent, R. D. Rhodes, is at Salt Lake City, and may remain there completing alterations at the U. S. smelter. Jas. Kerwin is filling Mr. Rhodes' place, with W. S. Keith as his assistant.

The Balaklala Copper Mining Co. is preparing for the erection of its matting plant just below Kennett, on the Sacramento river, the product of which will be shipped to the American Smelting & Refining Co.'s proposed smelting works at San Bruno, on San Francisco bay.

Kennett, April 9.

Tuolumne County.

(Special Correspondence).—Operations will be resumed at the Carlotta-Pennsylvania, one mile north of Tuolumne, about April 15. It is the intention to sink the two shafts, each at present 200 ft. deep, to a depth of 600 ft., connect them at this level and run crosscuts to intersect the six veins running parallel through the properties before milling ore. J. T. Thompson, the general manager, who has been in the East for some time, is here making necessary preparations. The mill will be increased from 7 to 15 stamps when the development work outlined has been completed. The shaft on the Carlotta is not on the same vein as that of the Pennsylvania, as these are about 500 ft. apart. These veins have an average width of 20 in. The last 100 tons of ore milled from the Carlotta went $19 per ton free gold. Numerous assays from the bottom of the Pennsylvania shaft showed $76 to $3,218 per ton, and a mill test of 600 lb. of ore from the same place gave $130.——A 10-stamp mill will shortly be erected at the New Calico mine, on the Mother Lode.——The Porto Fino mine, near Tuolumne, is being put in condition to enable Eastern people to inspect it. This property is near the Carlotta and Pennsylvania.——The new superintendent at the North Star has arrived and work will begin at once.

It is reported that the owners of the Grizzly and New Albany mines contemplate the erection of a 100-stamp mill. Since the company took the property large and valuable bodies of ore are reported to have been uncovered, and a great quantity of medium and low-grade rock is in sight. The most recent discovery of importance was made at the 900-ft. level, where the vein is 15 ft. wide, three feet of which is high-grade ore. A 20-stamp mill on the Grizzly crushes the ore from both mines, but a larger one is considered necessary to enable the handling of the low-grade ore profitably.——The Murphy Ranch mine, near Big Oak Flat, is being unwatered for inspection.

Tuolumne, April 10.

COLORADO.

Boulder County.

Arnold Hughes reports finding a three-foot vein of tungsten ore in the Mystery tunnel, near Eldora. The tunnel is in 160 ft. and cuts the vein 120 ft. in depth. A drift will be driven on the vein a distance of 200 ft. to tap the ore-shoot uncovered in the discovery shaft of the Mystery claim.

The United States Corporation tunnel is in over 1,500 ft. and 300 ft. more will cut the Klondike vein. The tunnel is being driven at the rate of 100 ft. per month. It is the intention to put on a double shift May 1. The Monroe vein, 600 ft. from the portal of the tunnel, is being developed with satisfactory results, 12 in. of sulphide ore showing in the face of the drift, which is in 60 ft. W. Mitchell, for a long time superintendent of the property, has been succeeded by G. Kneal. of Boulder. Mr. Mitchell takes charge of the United States Corporation's property at Sugar Loaf, which is to be extensively developed this season.

Clear Creek County.

A contract has been let to Peter Hector to drive the Wilcox tunnel an additional 1,000 ft., which will take the tunnel to the 4,900-ft. point, and to, if not beyond, the Kitty Ousley vein. Work has been commenced by Mr. Hector.——The three-compartment raise from the tunnel on the Commonwealth vein is about 160 ft. The ore-streak has been continuous.——In addition to the strike of 15 in. of copper pyrite on the Paymaster vein, there is adjoining the solid ore, similar ore, but more scattered and about two feet in thickness, of fine concentrating material. Superintendent Tingle says that in all the veins cut by the tunnel none show any appreciable amount of galena or zinc-blende, while the surface workings on the same veins produce nothing but galena and zinc. The line of the change in the character of the ore has not as yet been determined. Gold and copper have replaced the lead and silver, although the copper carries silver in addition.——Preparations are being made to resume work on the Stevens mine, and the mill will be put in operation as soon as there is a sufficient supply of water. It is the intention of the management to sink the shaft on the tunnel level to greater depth.——Grubb & Co. made a shipment from the Stemwinder last week that milled 99 oz. silver per ton.——Garbolino & Co. had a 13-ton shipment from the Comet which ran 40 oz. silver per ton.——A cave-in occurred on the Fort Dodge last week, 200 ft. in, which uncovered a vein of ore overhead.

Four men have been put to work in the stope on the Junction level of the Bonanza tunnel and shipments will soon commence.——The Terrible mill, which has been closed several months on account of the scarcity of water, was started up the first of the month.——Work has been going on for some time on the Pueblo property on Griffith mountain. The adit is in 700 ft., and a streak of lead and zinc ore has been opened up.——Lawrence & Robeson are about to complete negotiations for the Hall tunnel, which is in 3,500 ft. They intend to drive the tunnel ahead to cut the 1,000-ft. shaft of the Colorado Central mine, from which point the Hall properties can be easily and economically worked. It is thought that this will lead to the consolidation of the Colorado Central-Allunde and Hall properties, which will make one of the greatest combinations in the State.

Gunnison County.

More than 10,000 ft. of the Gunnison tunnel has been completed. The number of feet completed from each heading is as follows: Heading No. 1, 2,885 ft.; No. 2, 3,336 ft.; No. 3, 1,274 ft.; No. 4, 2,643 ft. Several accidents and breakdowns have occurred in the past few weeks to delay work, although at no time has work ceased on all headings, nor has more than two or three days elapsed before work was resumed. A large flow of water has been struck in the tunnel and pumps have been ordered and will be installed soon.

Ouray County.

Work has been continuous at the Bright Diamond and Memphis through the bad weather, and the shaft in the Bright Diamond is down 125 ft. and sinking. It is expected that the quartzite in which the shaft has been sunk will soon be passed and ore found beneath. Development has been going on in both mines. Fourteen men are employed in the Memphis and the Bright Diamond, and as soon as the quartzite in the Bright Diamond has been passed the force will be increased. All the mines north of town are looking promising.

At the Mineral Farm, near Ouray, all the machinery is now at the mine and its installation nearly completed. Wires will be run from the lines of the Telluride Power Co. to the mine and the machinery will be operated by electricity.

Work on the main tunnel at the Joker, near Ouray, has been stopped and crosscutting to the Yankee Girl started. Thirty-five men are employed.

Snow is reported to be five feet deep, and in the Park it is more than six feet deep.

The production of ore from the mines north of Ouray is being investigated. Plans have been under consideration for some time past for the re-opening of the old pyritic smelter, but nothing has been done in the matter as yet. It is believed, however, that the Slide-Newsboy, Bright Diamond, Black Girl and other mines in that district will produce sufficient ore to pay for the opening and operation of the smelter. There is a large amount of low-grade ore in the vicinity which hardly pay for shipping to Salida or Pueblo, but which would net good returns to the owners were the local smelter to be put in operation.

The Bachelor mill, near Ouray, is being repaired and will be operating within a short time. A large amount of ore is ready for treatment, and the output of the mines in that neighborhood will be increased as soon as the weather permits. Newton, Carr & O'Byrne, who are leasing on the Bachelor, will contribute materially to the operations of the mill. At present there are 60 men employed in the vicinity of the Bachelor, and it is said that the force will be increased to 100 men within the next 30 days. The ore-shoot of the Bachelor was discovered in the early '90s and has since produced a large amount of high-grade ore.

Park County.

(Special Correspondence.)—The Alma district is more prosperous than for some years past—no idle men, more properties shipping, fewer empty buildings, and an air of prosperity are noticeable.

The Moose is shipping and has struck some high-grade silver ore, which looks AI. Just what this strike will develop into remains for the future to determine. The Moose ore is packed down the mountain. The Atlantic is shipping and the showing is good for a continuous shipper.

The Hock Hocking is again in good ore and is shipping. This property has some low-grade zinc-lead ore blocked out, all of which carries some silver.

The Clipper is shipping and now has four four-horse teams hauling ore.

The Russia is shipping some fine ore, which is packed down, and anyone who thinks that packing ore from above timber line at this time of the year is a summer picnic should go up and make one trip with the packer, and just help dig out a few of the jacks after they are stuck in a snowdrift—temperature about zero and wind blowing a gale. That is one reason why a packer 'cusses' so hard; it seems to keep him warm.

The London is shipping a fine lot of ore; has four four-horse and three six-horse teams hauling. This is one of the big mines of Colorado. The principal values are in gold. The London fault is receiving a lot of attention just now. Pawless, Wolf, and others, are doing some development on the London fault, near the south end, on Sheep mountain.

Several other properties have ore out and are ready to ship as soon as the snow is off so they can get it packed down.

The Snowstorm Hydraulicking Co. is making arrangements to begin work with a force about April 15.

Alma, April 7.

Summit County.

(Special Correspondence.)—There have been several strikes of importance in the Frisco camp within the last week. Albert Newton, who is developing claims on the southeastern side of the Masontown Mining & Milling Company's property, has unearthed some rich float. It comes into his tunnel in the form of quartz carrying free gold. Assays of this have given from $5,000 to $15,000 per ton. On the Royal group, on the north of the Masontown property, Linquish & Heckman have sylvanite float which returned $3,780 per ton gold by assay.

The Masontown Co. are arranging to sink their main shaft and prospect for the vein from which this rich rock came and are also intending to work the rich sulphide ores which are opened up in the lowest level.——The Mary Verna Mining Co.'s main tunnel is in 740 feet.

The North American Mines Co. are pushing their tunnel into Peak I of the Ten Mile range. It is in over 1,000 ft. Driving on the large orebody recently passed through has been discontinued temporarily.

The Square Deal Mining & Development Co. is taking out a shipment of high-grade ore to be sent to the smelter and also a quantity of lower grade ore to have a mill run made at the Denver Ore Testing & Sampling Works. Their main tunnel is in 360 feet.

At Breckenridge the main tunnel of the Old Union Mining & Milling Co. has intersected the Old Union vein, 125 ft. below the upper workings and between the No. 1 and No. 2 shafts. This vein is 75 ft. from the Union vein along which the main tunnel was driven and which showed up good ore for over 1,000 ft. The water in the old workings will be taken out prior to making connection.

A lease has been secured by local operators on the Sultana group in the Yuba Dam Flats on the Blue river. This property is owned by St. Louis people who have not operated it for several years. It has a record of large production for silver, lead and zinc.

In the Country Boy mine on Nigger Hill the Lanyon Zinc Co. has an excellent showing. There is a two-foot streak of 45% zinc ore showing in the drift. Another carload shipment has been made and more are to follow. The lessees of the Germania mine have shipped another car of high-grade silver ore. The lower grade is being sent regularly to the market. The Colorado & Wyoming Development Co. have made a contract with the Old Union Mining & Milling Co. to deliver 2,000 tons of its dump ore from the Wellington mine for treatment at the latter company's mill.

Breckenridge, April 8.

(Special Correspondence).—The Pennsylvania mine of Argentine shipped several cars of silver-lead ore last week through the local branch of the Chamberlain & Dillingham Ore Co.

The management of the Old Union mine has now a force of men raising on ore recently struck in the main tunnel in the Old Union vein. This work, when carried up 125 ft., will make connections between the old upper workings and the lower workings of the new tunnel, giving free access of air without the necessity of the furnace which now supplies the ventilation.

The Abundance Mining & Milling Co. are making good headway with their main tunnel into Mineral hill. They are now in 460 ft., and three days ago passed through a small vein of good lead-zinc ore.

The Reliance gold dredge, in French gulch, started its season's work on Monday, the 9th inst., and is excavating about 2,500 yards per day.

C. C. Acton, owner and operator of the Chester mines in Summit gulch, is taking out a large quantity of free-milling gold ore which will average $20 or over per ton. This he will start to treat in his little mill early next month. The richer streaks of his six-foot vein run $500 to $600 gold per ton, this grade being shipped direct to smelters.

The Gold Dust Mines Co., operating on Nigger hill, has just received a carload of pipe and machinery for their long tunnel and to enable sinking below that level. The tunnel is in 3,500 ft., and the vein they are now working on is from 12 to 18 ft. wide, and three feet of this is high-grade silver-lead ore, the remainder being concentrating ore. Sinking will be started at once on a rich shoot and a pump installed.

The Laurium mine, in Illinois gulch, has been purchased from Niles & Walker, and the new company intends to enlarge the present mill and put on a large force.

Breckenridge, April 9.

Teller County.

The Portland Co. at Cripple Creek has begun working three shifts in nearly all parts of the mine. Up to the present but two shifts have been employed. The men will be lowered and hoisted through No. 2 shaft, from which operations throughout more than 30 miles of workings of the property will be directed. The two shifts in the Lowell shaft will be doubled into one, and in this department of the mine there will be room for two additional shifts. There is considerable ore in sight tributary to the Lowell shaft and its contiguous workings. It is believed that the production of the mine will be but little curtailed from its monthly average, as there are many ways in which the loss entailed by the fire may be almost made up.

The output for the month of March was $1,382,500, with a tonnage of 45,410. This is a falling off from February of $68,000, and the decrease in tonnage is 2,000. This is accounted for from several different facts.

The Findlay has been closed down throughout the month, the Portland fire caused a curtailment from this big producer. The flood in the El Paso was another feature, and the destruction of the Dorcas mill at Florence by fire helped to make the decrease. Another feature was that no cyanide mills are now in operation in the Cripple Creek district, although several will probably

be treating ore this month. The following table gives the individual treatment of ore by mills and smelters:

	Tons.	Total value.
Smelters	9,610	$480,500
Portland	8,000	208.000
Dorcas	1,800	45,000
U. S. R. & R.	25,000	625,000
Economic (Est.)	1,000	24,000
Total	45,410	$1,382,500

MISSOURI.

Jasper County.

The output of Joplin district in the first quarter of 1906 amounted to 128,526,240 lb. of zinc, which sold for $2,874,875, and 18,928,730 lb. of lead, which sold for $663,-725, the total value of both being $3,538,700. During the corresponding period in 1905 the production amounted to 113,885,470 lb. of zinc, which sold for $2,767,540, and 3,703,040 lb. of lead, which sold for $397,-435, a total value for both of $3,164,475. At this rate of increase throughout the year, the output for 1906 shows an increase of $1,500,000 in value of production over 1905. If the output of the last three months is maintained throughout the year a total value of $14,154,800 would be reached, as against a total value of $13,302,800 in 1905. The zinc ore market in the past month has been steady with top grades at from $49 to $51 a ton, the latter price prevailing early in the month, then weakening to $49, and again advancing to $51 a ton. During the past month the price of lead has fluctuated between $72 and $78, as compared to a top price of $58 a ton in the same time last year.

NEVADA.

Churchill County.

(Special Correspondence).—At present Fairview, a camp established about two years ago, is attracting considerable attention. In the range extending southerly from Fairview there are many prospectors, and one district, 20 miles south, called Monte Cristo, reports numerous promising discoveries. A large number of prospectors, miners, and adventurers of every class are rushing into the region in search of gold. Thus far the work being done is of a superficial character, as more attention is given to locating as many claims as possible, rather than to their development.

Fallon, April 7.

The Nevada Sand Springs Mining Co. has been organized at Reno by G. T. Crosby, J. M. Fulton, C. E. Clough, W. H. Wood and H. Anderson, all of Reno. The claims owned by the company are the Wild Rose, Lost Mule, Surprise and Copper King. On the Wild Rose there is a 60-ft. tunnel. Assays from quartz in this tunnel run $18 gold. Good assays have also been had from the Lost Mule, in a surface cut. A peculiar feature about these properties is what is known as the blue blow-out on the Eagleville and Austin road. Assays from this run $7 gold, on the surface. Five miners left recently to begin work on the Wild Rose, where a crosscut will be made.

A dispatch from Carson states that the newly reported gold discoveries near Cooney Springs has resulted in a general stampede to that section. It is said that early Wednesday morning a string of vehicles and autos left Carson for the new goldfields, Cooney Springs, and the town seems to have been almost deserted with the pell-mell rush for the new scene of the latest excitement. News comes from Virginia City and other towns that the stampede has affected them in the same manner. Tonight there are rumors of another strike within 20 or 30 miles of this city.

Esmeralda County.

Pfeifer, Kelly & Denham have a five-foot ledge of milling rock, near Aurora, and are building a new ore chute and will increase their force of men.——The McKeough Co. are piling up good ore and getting more blocked out in the mine.——The J. S. Cain Co. are working a night and a day shift on their mill, which is nearing completion.——The ore chutes of the Junietta are filled and they will have 5,000 tons of ore blocked out by the time the mill is ready to commence crushing.——Anderson is pushing development on his claims as fast as the weather will permit.——Clayton, Peterson & Co. have been handicapped by the bad weather, but are now blocking out ore and getting ready for the time when the snow will permit hoisting.——Cotton & Barnes, of the Big Injun Co., last week bought a group of three claims, paying cash therefor. They have a force putting the road in condition to permit the hauling of mill and other machinery, now in transit. The mill has a capacity of 15 tons daily. The millsite is being graded and a tramway surveyed. The tram will be one mile long. A large force of miners will be put on and systematic work pursued. The company owns 20 claims 14 miles west of Hawthorne.

Lincoln County.

(Special Correspondence).—There has been more activity here within the last ten days than ever before, and with the present boom there is no question but that Searchlight will be heard from as favorably, as her northern sister camps. Four mills are running night and day, and two more will be added to this list within the next thirty days.——A new strike of copper ore has been made three miles east of town; it has been reported that the vein measures 40 ft. across and has well-defined walls.——Matt Hoveck, superintendent and a director of the Montgomery-Shoshone mine, of Bullfrog, has bought an interest in the Cyrus Noble Extension here, and is president of this new company. L. L. Patrick and others of Goldfield, Bullfrog and Manhattan, have also acquired interests in this camp. This company has secured good property, and it is to be developed under supervision of Robert Lanka.

The Searchlight Diamond Gold Mining Co. commenced operations on their property this week. This company owns three claims one mile west of the Pompeii, and has three ledges traversing the ground; two are east-west leads, while the north-south lead is supposed to be the Cyrus Noble-Quartette vein. The ore at the bottom of the 65-ft. shaft runs $16 per ton. An electric plant, including hoist and pump, is now being installed.

Searchlight Parallel has opened a large body of ore on the 450-ft. level; drifting on the upper levels continues in order to block out the orebody that is now in sight. The company will continue sinking to such depth as the present hoist will permit.

The Searchlight Western Telegraph & Telephone Co. are extending their line to El Dorado Cañon; this should be completed in 15 days. This line will be of great assistance to El Dorado cañon as that district is the scene of much activity at present.

In El Dorado cañon district a strike has been made 150 ft. north of the Venus working shaft of free gold ore. A trench on a parallel ledge has opened up ore that will average $22 per ton, this being the general average for several feet. The Mountain group, which borders on the Venus, has a 30-ft. shaft in high-grade milling ore; the east drift exposes two feet of $500 ore, while a six-inch streak in the west drift runs $2,000 per ton gold. Several open cuts have been run, exposing good ore in a ledge that is from 40 to 60 ft. wide.

Searchlight Mining & Milling Co. have secured such good results in their recent developments that they have decided to add 10 stamps, making 20 stamps all told. This will mean a general increase in the equipment of machinery.

The Golconda Mining Co. has a force on their properties and intend to sink the shaft to the 300-ft. level. This property, which adjoins the Searchlight Mining & Milling Co., has an immense ledge running east and west through its entire extent. This is a new company, and they intend to install machinery in the near future.

Searchlight, April 8.

Three miles east of Searchlight, near Summit Springs, C. A. Caughman, F. J. Flanagan and J. H. Connors have located a mineralized zone traceable for a mile or more and having a width of anywhere from 60 to 400 ft. Little work has been done as yet, but it is believed that it will run well in copper, for besides the copper stain there is a heavy iron cap. The main showing is on the Minnie Haley, one of a group of five claims. A townsite has been taken up and named Emerald City. The strike is about a mile and a half east of the Quartette. The walls are well defined and the vein filling is decomposed quartz-porphyry, with some quartz. The whole vein is covered with a capping a few inches in thickness.——Installing the new air compressor at the Quartette is completed, and in a few days the drills will begin work on the ninth level, which is now opened for a distance of 50 ft. to the east and 30 ft. to the west, both drifts in ore, but the main ore-shoot is still some distance away.

Nye County.

(Special Correspondence).—In this district are many good showings and some established mines. One of the best mines in the district is developed to a depth of 700 ft., showing that the veins go down, assaying from $2 on the croppings, up into the hundreds per ton in gold in depth and increasing from two feet at surface to 30 ft. at 500 ft. depth.——New arrivals are changing conditions in this camp for the better. Miller and Lamprey have resumed sinking on their Silver mine, receiving via Salt Lake Railroad a quantity of lumber and general supplies. They are taking out ore for shipping.——Morrison, Place & Gould are also preparing to ship smelting ores.——'Trail' Johnson of Utah, who owns a group of mines on the east side of the Johnnie townsite and covering part of said townsite, has a shaft down 40 ft. and in a crosscut has the contact on west side with a fine body of good ore with a gouge. Another oil find is reported in Ash Meadows east of here a few miles.——The Lucky T. Co. are still driving their tunnel for the junction of their two big veins, under management of Mr. Muir. This company has driven a long tunnel at great expense, but surface work has proved they have a mine.—Rathburn, the company's storekeeper, is opening up a fine-looking body of ore between the Congress Co.'s grounds and the Bonanza Queen. He has only a fractional claim, but in this camp fractions are O K. He is postmaster, district recorder, notary and almost everything.——Fred Boller has leased some ground of the Johnnie Consolidated Co., which he says prospects $100 per ton on the croppings. He came here from Bullfrog last winter.——A company is being organized to open up the Del Oro mines, a group on the west of town, as soon as lumber, tools, supplies, etc., can be brought in. This property has shown $200 to $800 gold per ton. He has done enough work on it to justify further development. A mill will be erected this coming summer. The company has plenty of water for all purposes and ore enough on their claims to keep a mill running.——A. C. Swain while doing location work on a claim west of the Johnnie townsite has struck a 12-ft vein of mineral running through the townsite. It has a fine, soft gouge of yellow ocher carrying free gold; the quartz looks promising, but no assays have yet been made of it.——The Congress Co., Ramsey, Butler, Ish & Co., of Tonopah, owners, are getting ready to install a mill this coming summer after hoisting by whim and mule power all winter.

We shall soon have daily stage communication with the railroad as the sidings, etc., are being put in at Station 73, 30 miles northwest of Indian Spring on Las Vegas and Bullfrog (Clark's Railroad). Arrangements are also being made to have mail come the same way. With the advent of railroads, thousands of acres of Ash Meadows country will be settled by farmers and stock raisers, as there is an abundance of water for irrigating.

Johnnie, April 4.

(Special Correspondence).—From a group of claims 16 miles southeast of Las Vegas, locally known as the Catlin claims, come some good assays, showing high in gold, one being more than $1,000. The property has a shaft down 30 ft., this being the only work. There are a number of owners, and they are not all here, so it is difficult to say what will be done.——To the northwest from Las Vegas about 30 miles the Siebert group of silver-lead properties are piling up ore.——The Lane claims, on the Colorado river, 30 miles east, continue to show good results, but no systematic work is being done.——The washout on the S. P., L. A. & S. L. railroad north of here, which occurred March 24, is not yet repaired.

Las Vegas, April 10.

The Cowboy and Mother Lode mining companies are reported to have made big strikes. The Mother Lode Co. opened up ore last week on the Mule Skinner claim in the 60-ft. tunnel that will run $1,000 to the ton. The Mule Skinner claim adjoins the Manhattan Consolidated mine. On lease No. 4 of the Iron King, on the Cowboy Mining Co.'s ground, a rich pocket of gold ore has been encountered, some of which will run $10,000 per ton. On lease No. 3, at a depth of 40 ft., a four-foot vein was uncovered which shows free gold estimated from pannings to run $200 per ton.

Storey County.

Mr. Rae is preparing to start dredging operations in Gold cañon, representing the Virginia-Tonopah Dredging Co., owning 200 acres of ground in the vicinity of Dayton.—— Emmet Boyle is employing 10 men in development work on the North Rapidan and other ground owned by his company.—— The Ohio-Tonopah Co. has 20 men employed in blocking out what was formerly known as the Hulley-Logan mine, and has 500 ft. of backs. The company will erect a large milling plant this year. Several prospectors are also employed in developing their mining locations in the district.

A large sum of money is being raised in Virginia City and Gold Hill, Nev., for the forthcoming jubilee celebration of the discovery of the Comstock lode.

A find carrying high gold values was recently made by Goldfield prospectors near Cooney's ranch and springs, 16 miles northeast of Virginia City. For 25 miles to the eastward of Virginia City the hills are highly mineralized and other discoveries will probably be made. A stampede for Cooney's ranch is in progress. Flowery, Badger, Desert and Siegel districts are all in the same range of hills. There is water in the ravines and the Carson river is only three miles to the southward. A townsite has been surveyed and a new camp will soon come into existence in this section, which is west of Siegel district.

NEW MEXICO.

Dona Ana County.

In Ash cañon, San Andreas mountains, M. D. Gaylord and party have opened up five leads by blowing away with dynamite obstructions which covered old workings. When the Mexicans closed the mines they were sealed with stones and powdered lime rock mixed as cement, which soon took on the color of the cañon walls and obliterated all traces of the mine, the evidences of the workings having been carried back into the mine before it was sealed. Traces of smoke above former openings led them to prospect below, discover the cement and blow it out. Skeletons were found, and also rich ore. All the openings seem to belong to one mine, as they are close together.

Grant County.

(Special Correspondence).—C. P. Crawford, with Moses and Portwood, have secured a renewal of lease of shaft No. 7 of the Santa Rita mine at Santa Rita, and are shipping 50 tons of ore daily to the company's concentrator They are stoping an orebody several sets wide, and as soon as that is removed they have another ready to continue the work. The company attempted to work this same ground on several occasions, but failed each time to make the operation profitable. Crawford & Co. are making a good profit, demonstrating once more that leasers can make a profit where corporate management fails.

Santa Rita, April 8.

OREGON.

Baker County.

(Special Correspondence).—The mining country surrounding Baker City embraces such an extensive territory that no great excitement has ever occurred within its boundaries. The mineralized field is perhaps 100 miles square. It has never been carefully or scientifically prospected. Mining stampedes seem to occur only in districts of limited extent, where interest becomes centralized and enthusiasm escapes under pressure. Just now there is a copper excitement on, which approaches more nearly to a mining boom than anything eastern Oregon has experienced. The cause is the development that has been going on for about a year, at two points on the copper belt, twenty miles northeast of Baker City, and which has resulted in proving orebodies of magnitude and richness, and prospectors are flocking into this district.

The North American Co., an Iowa organization, pioneered the way into this section about six years ago, but subsequently became entangled financially, after which work ceased, to the discouragement of others who were watching the result. Two years ago an Indiana Co. commenced work on the copper belt, near Medical Springs, and recently, in a crosscut at the 200-ft. level, they have driven 25 ft. into a ledge of sulphide ore that will run five per cent copper, and about $5 per ton in gold and silver, and they have not yet reached the opposite wall. They have thousands of tons of ore on the dump, and are preparing for the erection of a reduction plant.

Following the success of the Indiana, the North American was revived last fall, and work resumed at their property at Burkemont, near the center of the copper belt, some time in December last. Fifteen feet below where work was suspended, the double-compartment shaft entered a body of native copper ore, carrying also gold and silver. Local interest is now centered on this property, as the shaft has been sunk continuously through 75 ft. of this ore, and the lower wall of the deposit is not yet in sight. A townsite has been laid off, a postoffice established, and the country on both sides of Burkemont is full of prospectors locating everything in sight. The North American is under the supervision of D. W. C. Nelson, who is planning for the erection of a concentrator. The native copper ore in this mine runs from four to six per cent in copper. At the present depth

of 230 ft. there are beginning to appear chalcopyrite and copper glance.

The distinctive feature of the ore deposits on this belt is their great size, which, taken in connection with the extent of this copper belt, justifies the belief that the copper interests of the country will some day include eastern Oregon among the important producers of the red metal. This furnishes also an explanation of the wide-spread interest among mining men now being focused on this district.

The gold camps surrounding Baker are manifesting unusual activity, as a reflex from the copper excitement. Many new properties are being opened in the Sumpter camp, which will be added to the list of producers during the coming year. One of the notable new properties is the Gold Coin mine, near Durkee. It is owned by Ayers & White, of Pendleton. This is a low-grade proposition in which the management proposes to quarry from a conglomerate ledge, 75 ft. wide, ore that will average about $5 per ton in free gold. They are adding to the 10-stamp mill, already on the property, 90 additional stamps, which will constitute this the largest mill in Oregon.

Another new property is being opened in a comparatively unknown district, about twenty-five miles east of Baker, where the Timber Canyon Co., under management of F. J. Davey, is erecting buildings preparatory to installing a mill. In this Timber Canyon mine, it is reported, they have three feet of ore that will average $50 per ton in free gold. Lying between this property and Baker City, in the old Virtue district, at least two new properties will be equipped with mills during the present year. They are the Dan and the Pat properties, on which developments are now in progress. The old Virtue itself, with a record of over $3,000,000 in gold, is steadily producing under the management of W. L. Vinson.

Baker City, April 7.

SOUTH DAKOTA.

Lawrence County.

In the mining operations recently undertaken on the piles of mill and placer tailing in Deadwood gulch, near the mouth of Blacktail, between Central City and Deadwood, several mill-runs have been made.

Fifty tons were treated in the first test run, and $2.80 in free gold per ton saved on the plates, the tailing (suitable for cyanidation) assaying, $5.88 per ton. During the test mentioned trouble was experienced by the breaking of screens and the free gold recovery was low. In a second test $3.40 per ton was saved by amalgamation, and tailing averaged $4.80.

A few feet from the mill a shaft has been sunk to bedrock where the bedrock is 32 ft. from the surface. The hoisting engine is set in the upper portion of the mill, and an incline track runs to the bottom of the shaft. The débris will be mined by open cut system no powder being needed. The ground is loose and can be shoveled. The company proposes to erect, lower down the gulch, a second amalgamating plant of 100 tons daily capacity, and a cyanide plant for both mills close to the second mill.

Pennington County.

J. B. Baker of Lead is making arrangements at Rochford to begin work on the Standby mine. This property has been worked at intervals since 1879. It is equipped with a 60-stamp mill. Mr. Baker will start work on the installation of an air compressor which is on the ground. Cold weather has interfered with this work.

Ten stamps will be fixed up and started. This will be an experimental run on several hundred tons of ore. It is reported that recently the workings have penetrated one of the best orebodies that has ever been opened up in the mine, and that the grade is good.

At Rapid City work has been in progress some time on repairs and alterations at the National smelter, in expectation of starting the plant on April 15. It will be operated as a custom plant, and it already has contracts with mining companies of the Northern Hills to handle their entire output of smelting ores, in addition to which part of its supply will be drawn from the mines along upper Rapid creek. It is proposed to start with one furnace and as soon as business warrants the other furnace will be blown in. The smelter will be in charge of C. H. Fulton, president of the State School of Mines at Rapid City.

The Mariposa Gold Mining Co , at Mystic, on Castle creek, has received machinery for the new plant, including gasoline engine, air compressor and rock drills. The company is equipping for systematic development.

UTAH.

Weber County.

(Special Correspondence).—The Oregon Short Line Railroad Co. has started a grading outfit to work on preliminary construction of a spur leading to the site of the new smelting plant, that will be erected by the Utah Smelting Co., seven miles north of Ogden. When this track has been completed, the material necessary for the building of the smelter will be shipped in and construction work of the plant will be commenced. It is expected that it will be completed and ready for business within six months. This plant will be the first independent smelting concern to enter the field since the trust gained control of all the smelting interests of the country and is, therefore, looked upon as an important move and one that may make Ogden a prominent smelter point. This can be better understood when it is remembered that two months ago Charles M. Schwab, under a threat to start an independent smelter on the coast, forced the trust to grant him a reduction of $5 per ton on all his ores. Mr. Schwab went so far as to lease an old abandoned smelting plant, near San Francisco, but when he secured the reduction mentioned he abandoned the idea of operating it. The actual operation of an independent concern would probably be favorable to the producers.

The Utah Smelting Co. is backed by a strong combination of capitalists, its president being David Eccles, of Ogden.

Ogden, April 7.

WYOMING.

The value of mineral output of Wyoming, as returned for assessment last year, was $1,710,612.23. The total tonnage mined was 6,006,883.14 tons, of which 534,879 tons were iron, and 25,000 tons were copper. The coal sold for an average of $4 per ton, and the copper netted the producers over $500,000.

The tax value per ton on coal and ores was fixed by the bill passed by the legislature four years ago, and is not the actual value of the product, thus explaining the vast difference shown in the valuation of the output for taxation, and the actual value. The tax on mines will bring the State about $50,000 a year.

Carbon County.

The smelting, concentrating, electric and steam power plants of the Penn-Wyoming Copper Co. at Grand Encampment was destroyed by fire on March 28. Loss is estimated at $300,000, partially covered by insurance. The smelter building was saved after a hard fight. The origin of the fire is unknown. The plant had been closed down for the winter on account of the deep snow and improvements under way.

J. B. Hassett, general manager of the Charter Oak mine, reports finding a vein of high-grade copper sulphide in a drift from the 200-ft. level in the mine, the vein being 2½ ft. wide and the ore running 48 to 50% in copper. A large body of low-grade ore was found adjoining the high-grade vein.

FOREIGN.

CANADA.

BRITISH COLUMBIA.

Windemere District.

What is reported to be the largest body of lead ore discovered in British Columbia has been developed this winter at Spillimacheen, half way between Windemere and Golden, and near the line of the Kootenay Central Railroad, upon which the work of construction is soon to begin. The mine, the Giant, is not a new find. While the once famous Blue Bell of Pilot bay, on Kootenay lake, was the first claim in all Kootenay to be recorded, it is claimed the Giant was first located. In the early '80s a mail carrier, who made monthly trips from Golden to Wild Horse, learned from the Indians that they procured the lead for their bullets from the west side of Spillimacheen mountain. The mail carrier, named Bray, got a prospector named Cannon, who was among the first in the Cœur d'Alene, to visit the find. When Cannon saw it he thought it galena, such as he had seen in the Cœur d'Alene, but an assay proved so disappointing that he gave the ground no further notice. Thomas Jones located the property in 1884, but nothing was done until 1890, when Mr. Jones did some work, which so improved the property that Mr. Cowell of Victoria bought it and did considerable development, finally closing down and allowing it to be sold 10 years later for taxes. Mr. Jones, who lives in the valley and is a practical miner, believing the Giant ground good property, kept it in sight, and when he found the claims for sale he got Mr. Devlin, of Golden, and Captain Armstrong, of the Upper Columbia River Navigation Co., interested, and they bought it. Mr. Jones began to work the claim last fall, and miners who have been employed say the ore today is remarkable. Several mining men have lately visited the mine and pronounce it great. E. A. Haggen, of the Frank Smelter Co., reported the vein to be 178 ft. wide, and the face of the crosscut was from 4 to 30 ft. high. A selected sample over the 178 ft., across the veins, assayed 3 oz. in silver and 79% lead. In the lower tunnel, 400 ft. below, the ore goes 12 oz. silver and 20% lead. Several carloads have been shipped and preparations are being made for next summer's work, and a bridge is being built over Spillimacheen river.

Yale District.

The output of Boundary mines for the week ending April 7 was as follows: Granby mines to Granby smelter, 14,038 tons; Mother Lode to British Columbia Copper smelter, 4,384 tons; Brooklyn-Stemwinder to Dominion smelter, 3,366 tons; Sunset to Dominion smelter, 875 tons; Emma to Nelson and British Columbia Copper smelter, 875 tons; Rawhide, 132 tons; total shipments for the week, 23,120 tons; total for the year to date, 336,485 tons.

Smelter treatment for the week was: Granby works, 16,641 tons; British Columbia Copper works, 4,220 tons; Dominion works, 4,373 tons; total for week, 25,234 tons; total for year to date, 351,950 tons.

The output of the Boundary mines for the week ending March 31 was as follows: Granby mines to Granby smelter, 16,366 tons; Mother Lode to B. C. copper smelter, 4,300 tons; Brooklyn-Stemwinder to Dominion smelter, 3,235 tons; Rawhide, 264 tons; Sunset to Dominion smelter, 960 tons; Emma to Nelson and B. C. smelter, 400 tons; Oro Denoro to Granby smelter, 150 tons; total, 25,675 tons. The output of the smelters was: Granby Co., 17,887 tons; B. C. Copper Co., 4,420 tons; Dominion Copper Co., 4,468 tons; total, 26,775 tons.

Shipments for the week ending April 7 from the Yale-Kootenay mines amounted to 30,970 tons, and for the year to date 460,018 tons. Shipments from Boundary mines were 23,123 tons, from Granby, Mother Lode, Rawhide, Ema, Sunset, Brooklyn, Skylark and Strathmore (the last named a new mine). From Rossland shipments were 5,485 tons, from Le Roi, Le Roi Two, and Centre Star-War Eagle. From Slocan-Kootenay the shipments were 2,216 tons, a record for this year, from St. Eugene, Sullivan, La Plata, Eureka, Hunter V, Black Prince, Broadview, Ottawa, Lone Bachelor, Queen, Kootenay Belle, Sallie, Second Relief, North Star, Whitewater, Ruth, Emerald, Majestic, Aurora, Silena and Queen-Dominion—the last three being new shippers. Ore reports at the smelters were: Granby, 14,068 tons; Dominion Copper, 4,564; Trail, 6,770; Hall mines, 761; Marysville, 500.

The B. C. Mining & Development Syndicate, with headquarters at Rossland, is preparing to ship more supplies to their mines near Marysville as soon as the roads will permit. They have had men engaged all winter under contract, and the ore is showing up well. They will increase their force and push work as fast as conditions will permit.

Mr. Leavick, representing capitalists of Colorado, has a number of properties under bond, the principal being the Mystery, owned by Robert Dwar, and situated on Alki creek. He has let a contract for the construction of a wagon road from the main road to the Mystery, and, as soon as this is opened, prospecting will be carried on by the aid of a diamond drill.

YUKON TERRITORY.

The dredging season in the Klondike has terminated, and so successful has been the record in that line of industry that there are prospects of five or six dredges being added to the number already here during the season of 1906. W. H. Isom, vice-president of the N. A. T. & T. Co.; J. M. Elmer, superintendent of the Bear creek dredge and the Lewis river dredge, and Otto Brener, managing director of the Canadian-Klondike Co., which owns the Bear creek dredge, the Williams Concession and water ditches, the French Hill hydraulic properties and plant, and other properties, are all likely to put dredges on the properties this year. Mr. Brener says two more dredges will be placed on his company's Bear creek property and the Bonanza Basin people plan to put in four more. It is known that Treadgold, who owns numerous claims on Bonanza, intends to put a dredge on Bonanza, and the Anderson Concession people are planning to put in two dredges, or more. The Moncrieff people may put in a new dredge, and others are working with similar intentions. It is likely that the majority of these dredges will materialize before spring, and that the White Pass will have another busy season hauling heavy material to Dawson. J. M. Elmer originated the dredging industry in the Yukon basin. He went to Dawson in 1901 with the Lewis river dredge, the first dredge of the Yukon basin and the north, demonstrated it a success in working the Klondike gravels, and last winter succeeded in persuading capital to put in the big dredge at the mouth of the Bear, which cost $200,000, and which has almost, if not quite, paid for itself since it started running for the first time, two months ago. Mr. Brener, of the same company, is also to be given credit for a good part in the financing of the company, but to Mr. Elmer is due the credit of demonstrating the Yukon as a dredging field.

MEXICO.

Chihuahua.

Weisel & Kock, engineers and contractors at Parral, expect to have completed the installation of Pedro Alvarado's 1,000-h.p electric power plant in the next six weeks. All of the machinery is on hand for this plant. It is to operate the Pamilla mine and Sr. Alvarado's rock quarries. The power plant being installed is arranged as one unit, and if it works satisfactorily, Weisel & Kock will install for Alvarado another unit of the same capacity.——The Naica Mining Co., of which G. C. Beckman, of Parral, is general manager, is sinking a shaft of the Felicidad mine in the Naica camp. The property consists of 45 pertenencias.——The Pittsburg Mining Co., B. M. Ray, superintendent, has installed new boilers and pumps and is unwatering its mines in the Santa Barbara section of the Parral district. The Cavaritas mines had been drowned out.——J. F, Johnston, of Parral, is working five mines, three in Chihuahua and two in Durango. Those in Chihuahua are, one near San Francisco del Oro, in the Parral district; one near El Valle, and another in the Sierra Almoloyo district. Those in Durango are, one near the San Juan de Nuñez and the second near San Jose de la Paz. Most of these properties are lead-producing. Mr. Johnston is planning a smelter for Jimenez.——The mine operators of the Santa Barbara section of the Parral district are complaining of car shortage, which prevents the shipment of ores to the smelters. In the vicinity of Santa Barbara there is a greatly increased activity in mining, and the output of ores of shipping grade is the result, but the Mexican Central has been unable to furnish the cars.

Obituary.

ROBERT PFLUEGER, of 927 Linden street, Oakland, Cal., a pioneer miner of Nevada and California, died on April 2 at his home, aged 85 years.

JOHN CHRISTIAN KAFER, past-president of the Engineers' Club, died at Trenton, N. J., on March 30, at the age of 64 years. He had for years been an active member of the Engineers' Club, and was for years connected with the iron industry.

NATHANIEL SOUTHGATE SHALER died at Cambridge, Mass., on April 10. As dean of the Lawrence Scientific School, of Harvard University, he was widely beloved by the men of two generations, and as a geologist he achieved an early distinction. Professor Shaler was born at Newport, Ky., on February 20, 1841, and therefore was more than 65 years of age. After graduating at Harvard in 1862, he served for two years in the Union army during the Civil War and subsequently, in 1868, he became instructor in geology at the Lawrence Scientific School and eventually full professor. He was the author of many books and possessed an extraordinary range of literary talent. His writings include a text-book on geology, popular treatises on this subject, pamphlets on paleontological and geodetic matters, a number of volumes dealing with sociology and finally three volumes of verse, dealing in dramatic form with the Elizabethan period. But Shaler will be remembered for himself as long as his writings are read, which means that the man was a greater influence than the pen he wielded. Like Werner he possessed to a rare degree the power of stimulating the enthusiasm for scientific study, and it was that more than the matter of his lectures that made him a powerful teacher. He was beloved of the Harvard students, who came to him for advice and encouragement. Few scientific men had such a wide acquaintance, and to none will it be given to be remembered more affectionately.

Personal.

C. W. PURINGTON is at Boston.

ALBERT F. HOLDEN is in San Francisco.

J. M. MCGEE, of Oroville, is at the St. Francis.

F. F. SHARPLESS is on his way to the Northwest.

CHARLES CLAY, of Forest Hill, is at the Occidental.

W. G. MOORE has left London to proceed to Borneo.

J. H. KINKEAD is in San Francisco, from Virginia City.

F. C. ROBERTS is inspecting mines in Durango, Mexico.

GEORGE J. BANCROFT has returned to Denver from Mexico.

THOS. H. LEGGETT is expected in New York, from Mexico.

W. E. DEFTY has gone to Los Angeles, on his way to Sonora, Mexico.

W. C. WYNKOOP is visiting San Francisco from Tonopah, Nevada.

EDGAR RICKARD has returned from his visit to Denver, Chicago and New York.

HORACE F. EVANS is investigating mines near Granite Creek, British Columbia.

CHARLES MADDOCK has arrived in New York on his way from London to Mexico.

JAMES A. SNEDAKER, of Denver, was in San Francisco, on his way from Nevada.

JOSEPH LUCE, of Salt Lake City, has come to California to take a well-earned rest.

FREDERICK GRUNDY, of Los Angeles, is in northern Arizona on professional business.

A. H. CURTIS, manager of the Clifton mine, in Rhodesia, is returning to England.

P. W. K. ROBERTSON is general manager of El Plomo mines, at Altar, in Sonora, Mexico.

R. J. WISNOM, in charge of the Butters cyanide plant at Virginia City, is in San Francisco.

F. A. STEARNS has returned to San Francisco from the Aros river, in Chihuahua, Mexico.

T. C. CLOUD, of the firm of Steinhart, Vogel & Cloud, London, is on his way to the Argentine.

HAROLD RICKARD has resigned as superintendent of the San Rafael mine, at Zacatecas, Mexico.

GEORGE W. MAYNARD visited San Francisco on his return from Sonora, Mexico, to New York.

W. H. TREGANOWEN, recently with the Champion Reef mine, in India, is on a visit to England.

H. R. PLATE has gone to Idaho to examine mines; will return to Denver about the end of April.

F. J. BOOTH has gone to Mexico to accept a position with a copper mining company in Chihuahua.

R. D. RHODES, superintendent of the Mammoth smelter, at Kennet, Cal., is at Salt Lake City.

EDMUND JUESSEN will be in Utah the greater part of April, making mine examinations.

JOHN HANLON, superintendent of the Crownpoint mine, near Prescott, Arizona, is visiting San Francisco.

E. W. SEBBEN has recently returned to Denver from a long stay in Arizona, where he examined a number of mines.

HOPE NICHOLSON has been appointed superintendent of the Cosmopolitan mine, at Kookynie, Western Australia.

H. E. WEST sails from Vera Cruz on April 4 to take the technical management of the Berlanga lead mines in Spain.

FREDERICK LEON is in charge of the San Francisco office of the United States Smelting, Refining & Mining Company.

R. H. BURROWS has resigned as manager of the Mineral Development Co., and has opened an office at Guanajuato, Mexico.

FRANK LONGMAID has severed his connection with the Vacas Mining Co., of Durango, and has moved to Cleveland, Tennessee.

J. C. DALY, JR., of Boston, has gone to Hayden Hill, Lassen county, Cal., to accept a position with the Hayden Hill Mining Company.

EDWIN C. HOLDEN is at St. Luke's Hospital, Denver, recovering from a broken leg, sustained while engaged in professional work in New Mexico.

GEORGE S. BINCKLEY, who is constructing an electric railway and complete water-works system for the city of Monterey, Mexico, is in San Francisco.

F. R. HUTTON has resigned as secretary of the American Society of Mechanical Engineers, but he is likely to be elected honorary secretary, with a paid secretary as assistant.

EDWARD H. NUTTER has resigned the superintendency of the Standard Mining Co., at Bodie, to become assistant superintendent at the Liberty Bell mine, at Telluride, Colorado.

WILLARD S. MORSE is about to go to Europe on a prolonged leave of absence, and in consequence the executive committee of the American Smelting & Refining Co. has placed the affairs of its southern department in the hands of WILLIAM C. POTTER, EDWARD C. KNIGHT and T. S. AUSTIN, with headquarters at Aguascalientes, Mexico.

METALS.

SILVER.—Per oz., Troy: New York, (by wire), bar silver, 64½c. per fine ounce; San Francisco, 64½c.: London, 29¾d. (standard ounce, 925 fine); Mexican dollars, 50@51c., San Francisco; 49¾c., New York.

COPPER.—Herewith are given the average prices of copper for the periods specified, as received by wire from New York:

	Week ending April 12.	Week ending April 5.	Average for March.
Lake	18.62@18.75	18.62@18.75	18.50@18.67
Electrolytic	18.25@18.50	18.25@18.50	18.24@18.43
Casting	18.00@18.25	18.00@18.25	17.87@18.17

Mill copper plates, 21c; bars, 21@24c. London, £84 10s. 6d.

LEAD.—New York (by wire, average for week ending April 12), $5.35 per 100 lb; San Francisco, pig, 5.70@6.60c. per lb.; pipe 7¾c.; sheet, 8¼@9¼c.; London: £15 15s. ℔ long ton.

SPELTER.—New York (by wire, average for week ending April 12), $6.07 ℔ 100 lb.; London, £25 12s. 6d. ℔ ton; San Francisco, ton lots, 7c.; 100-lb lots, 7¾c.

TIN.—New York, pig, $38.30@38.65: bar tin, ℔ lb., 42¼c.; pig, 39c. London, £176.

PLATINUM.—San Francisco, crude, $18.50 ℔ oz.; New York, ingot, nominal, $23@25 ℔ Troy oz. Platinum ware, 75@$1.00 ℔ gram.

QUICKSILVER.—New York, $40.00@$41.50, large lots; London, £7 7s 6d.; San Francisco, local, $39.00 ℔ flask of 75 lbs.

NICKEL.—New York, 48@60c ℔ lb.; ton lots, 40@47c.

ZINC.—Metallic, chemically pure, ℔ lb., 50c.; dust, ℔ lb., 10c.; sulphate, ℔ lb., 4c.

BABBITT METAL.—San Francisco, No. 1, 10½c.; No. 2, 8c.; No. 3, 7½c.; extra, 17½c.; genuine, 32½c.; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 23.50c; San Francisco, Plumbers', 100-lb. lots 19.75c.

ALUMINUM.—No. 1, 99%, small lots, 35@38c. ℔ lb.; 100 lbs., 35c.; 1000 lbs., 34c.; ton lots and over, 33c., Pittsburg. No. 2, 90%, small lots, 34c.; ton lots and over, 31c, Pittsburg.

STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, 18.10@$18.35; gray forge, $16.85; San Francisco, bar, 3½c. ℔ lb., 3¾c. in small quantities.

STEEL.—Bessemer billets, Pittsburg, $27.00 open hearth billets, $28.00; San Francisco, bar, 7c to 13c ℔ lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 8½c.; less than 500 lb., per lb., 8¼c.; in 25-lb. tin pails, ¼c. ℔ lb. above keg price; in 1 and 5-lb. tin cans, 100 lb. per case, ¼c. per lb. above keg price. Dry Lead.—In bbl., 1 ton and over, 8c.; do. in kegs, 8¼c.

LIME.—Santa Cruz, $1.35 country, $1.25 city ℔ bbl.

CEMENT.—Imported, $3.00@4.00 ℔ bbl.; California, carload lots, $1.80 f. o. b. at works; small lots, $2.10 ℔ bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

LUMBER.—(Retail): Pine, ordinary sizes, $24.00@25.00; extra sizes higher; redwood, $28.00@30.00; lath, 4 feet, $4.50@5.00; pickets, $21.00; shingles, $2.50 for No. 1, and $2.25 for No. 2; shakes, $13.50 for split and $15.00 for sawed; rustic, $28.00@35.00.

NAILS.—This week the basic prices are: Wire, $1.85; Cut, $1.75. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, $3.35; Cut, $3.55; 10d to 16d, Wire, $3.45; Cut, $3.35; 8d, Wire, $3.50; Cut, $3.50; 6d and 7d, Wire, $3.60; Cut, $3.60; 4d and 5d, Wire, $3.70; Cut, $3.70; 3d, Wire, $3.85; Cut, $3.85; 2d, Wire, $4.10; Cut, $4.10. Special rates for carload lots.

GENERAL SUPPLIES.

ANTIMONY.—New York, per quality, 18½@19½c; San Francisco, 1000-lb. lots, 20c; 300@500-lbs. 21c, 100-lb. lbs. 22c; 100-lbs lots, 23c.

BONE ASH.—Extra No. 1, 6c ℔ lb; No. 1, 5c½.

BORAX.—Concentrated, 9½c ℔ lb; powdered, 10c; fused, 25c; crystal, refined, 8c.

CANDLES.—Standard Oil Co.—Electric light, 16 oz., 11½c: 14 oz.,10½ c; 12 oz., 9c; Hotel, 12 oz., 9½c; Granite (mining), 16 oz., 11½@12c; 14 oz., 10½@10¾c; 12 oz., 9¾c; 10 oz., 9c; Paraffines, White, 1s, 2s, 4s, 6s, 11c; 12s, 11½c; colored, 1c higher; Radiant Paraffines, 4s, 6s, 14 oz., 10½@10¾c; 10 oz., 8c.

CAPS.—3x, $5.50@6 per 1000; 4x, $6.50@7; 5x, $8@8.50; Lion, $9@9.50, in lots not less than 1000.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1**, 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2**, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, $1.50 per keg; less car lots, $2.00 per keg.

CHEMICALS.—Cyanide of potassium, 98%–99%, jobbing, 23@24c ℔ lb.; carloads, 23@23½c; in tins, 30c; soda ash, $2.00 ℔ 100 lbs.; hyposulphite of soda, 3@3½c ℔ lb.; caustic soda, in drums, 3@3½c ℔ lb.; Cal. s. soda, bbls., $1.10@1.20 ℔ 100 lbs.; sks., 90c@$1.00; chlorate of potash, 12@13c; nitrate of potash, 6½@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2¾c; powdered sulphur, 2¼@2½c; flour sulphur, French, 2¾@—c; alum, $2.00@2.25; California refined, 1½@2c; sulphide of iron, 8c ℔ lb.; copper sulphate, 6½@7c; chloride of lime, spot, $2.50@2.75; sulphuric acid, in carboys, 66% B, 1½@2c ℔ lb.; nitric acid, carboys, 8c ℔ lb.

COAL.—San Francisco, coast, yard prices to dealers: Wellington, $7.50; Seattle, $6.50; Coos Bay, $5.50; Cargo lot, Eastern and foreign: Wallsend, $7.50; Brymbo, $7.50; Pennsylvania, hd., $14.00; Scotch, $8.00; Cumberland, $14.00; Cannel, $8.50; Rock Springs, $8.50, long ton; Colorado Anthracite, $14.00. Coke, $11.50 per ton in bulk, $13.00 in sacks; Sunnyside, $8.50, long ton.

OILS.—Linseed, boiled, bbl., 56c; cs., 61c; raw, bbl., 54c; cs., 59c; Lucol oil, boiled, bbl., 48c; cs., 53c; raw-bbl., 46c; cs., 51c. Kerosene—Pearl, per gal., 17c; Astral, 17c; Star, 17c; Extra Star, 20c; Eocene, 19c; Elaine, 26c; Water White, in bulk, 10½c; Mineral Seal, iron bbls., 18½c; wooden bbls., 21c; cs., 24½c; Mineral Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 15½c, do., cs., 22c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 12½c; do., in cs., 19c; Lard Oil, E. W. S., bbl., 65c; cs., 70c; Neats-foot Oil, pure, bbl., 63c; cs., 78c; Sperm, crude, 53c.; Natural White, 68c; Bleached, do., 57c; Whale Oil, cs., 57c.

FIRE BRICK.—Domestic, carloads ℔ 1000, f. o. b., factory square, $25.00; soap and split, $22.50; arch and wedge, $27.50; skewback, $30.00; circle, $32.00.

BISMUTH.—Subnitrate, ℔ lb., $2.10.

CHROMIUM.—90% and over, ℔ lb., 80c.

FIRE CLAY.—Domestic, ℔ ton 2000 lbs. in 125-lb. bags double, and dry ground, f. o. b., factory, $8.50.

FUSE.—Triple tape, $4.00 per 1000 feet; double tape, $3.55; single tape, $3.10; Hemp, $2.85; Cement No. 2, $3.10; Cement No. 1, $2.75, in lots of 3000 and up.

LITHARGE.—Pure, in 25-lb. bags, 9½@10½c ℔ lb.

MOLYBDENUM.—98@99% N. Y., $1.75 ℔ lb.

PHOSPHORUS.—American, ℔ lb., 70c.

RED LEAD.—500 lb. and over at one purchase, ℔ lb., 8½c.; less than 500 lb., 8¼c.

SILVER.—Chloride, ℔ oz., 90c@$1.00; nitrate, 54c.

SODIUM.—Metal, ℔ lb., $1.

TUNGSTEN.—Best, ℔ lb., 90c.

URANIUM.—Oxide, ℔ lb., $3.40.

Commercial Paragraphs.

W. E. DEFTY, of Phœnix, Ariz., has placed an order for mining machinery with the Fulton Iron Works, of San Francisco.

THE Denver Balance Co., 3000 Larimer street, Denver, manufacturers of assay balances, are doubling their floor space on account of increased business.

N. D. PHELPS, manager of sales, and CHARLES E. BRUFF, mining and crushing department, Power & Mining Machinery Co., have returned to Milwaukee from Salt Lake City and Denver.

CHARLES WAINWRIGHT, formerly superintendent of the Blaisdell Machinery Co., of Bradford, Pa., is now superintendent of the Bury Compressor Co., Erie, Pa. S. R. Warner, for years with the Ball Engine Co., of Erie, Pa., is now general States manager for the Bury Company.

THE suit of the De La Vergne Machine Co. against Theodore Kolischer and the Standard Ice Manufacturing Co., of Philadelphia, Pa., which was taken to the Supreme Court, has been finally decided in favor of the De La Verge Machine Co., and a judgment amounting to $130,706.33 rendered in their favor.

THE executive force of the Mine & Smelter Supply Co., consisting of J. H. Fennessy, president; A. L. Fennessy, treasurer; C. N. Tibbitts, general manager; A. E. Loizeau, assistant secretary; W. B. Kinkead, purchasing agent, and F. A. Fleish, traffic manager, will have their general offices at 42 Broadway, New York. A. H. Seep will remain in Denver in charge of all the branch houses.

Trade Treatises.

The Cyclone Drill Co., of Orrville, Ohio, has issued a circular describing their hand-power core drill.

The C. A. Bartlett & Snow Co., of Cleveland, Ohio, have issued Bulletin No. 17, descriptive of their rotary driers, and Bulletin No. 18 on conveying machinery.

Power & Mining Machinery Co., of Cudahy, Wis., have issued Catalogue No. 4, describing rock-crushing machinery, with many excellent halftone engravings and line drawings.

EDITORIAL.

AS stated in our last issue, the offices of this journal are now at Berkeley, where we have secured an excellent suite of rooms in the First National Bank building, a new five-story steel structure of the best type, which went through the recent severe test without a mark. In an adjoining building is the Standard Publishing Company, with whom we have made arrangements for printing. The linotype machines and the Miehle presses, together with other mechanical appliances, are all of the best; and in addition to this equipment, we have secured the cooperation of the public-spirited gentlemen who control the establishment.

IT was a merciful coincidence that among the few structures which did not succumb either to the earthquake or to the sequel of fire, were the Mint and the Post-office. The millions of currency stored in the first will be a prime factor in re-establishing financial conditions, while the preservation of the mail service will promote organization. As the disaster came at dawn, there was not much mail in the boxes and chutes, they having been cleared before midnight; moreover, the earliness of the hour saved the incoming mail, which was on the trains.

A few hours after the earthquake, we telegraphed to the authors of contributions that were lost when our office in San Francisco was demolished. By reason of their prompt response, we received copies of many of the articles within the week following the disaster. This is one of the advantages of the modern use of the type-writer. Formerly, authors had to trust to the preservation of their original copy, so that fires consumed a vast amount of valuable manuscript of which no duplicate had been preserved elsewhere.

THE value of a self-contained machine or complete unit is strikingly proved by the timely service given by the motor car during the conflagration. It is true there is many a wrecked automobile now lying in the streets of the ruined city, but the accident or damage that brought the activity of the machine to an end, did not take place until it had served a beneficient purpose, with wonderful efficiency. In removing wounded, in carrying doctors, in bringing dynamite for the blasting operations, in transporting food and, last of all, in aiding the escape of the terrified people, the motor car was of immense service. It was the only means of rapid locomotion.

"IT is an ill wind that blows no one good." There is evidence forthcoming from the conflagration in San Francisco, such as will stimulate the demand for copper. Our friends who are engaged in mining the red metal will be interested to know that the offices in the Kohl building, one of the best, and in many respects the most modern in construction, or all the larger structures in San Francisco, was protected by copper. The doors, casings and bases, all the interior finish of the offices, together with window-sashes, are covered with sheet copper. The people who have offices in that building, above the sixth floor, have found their papers intact. This use of copper is comparatively recent and the evidence just quoted should do much to encourage the innovation.

IT is our privilege to publish several special articles dealing with recent occurrences. That on 'The Cause and Nature of Earthquakes' is by Mr. G. K. Gilbert, of the United States Geological Survey, and a scientific authority second to none. Mr. A. O. Leuschner, who describes the seismograph records, is director of the observatory at the University of California. A suggestive article on 'Some Lessons from the Earthquake' is by Mr. S. B. Christy, professor of mining and metallurgy in the University of California. He needs no introduction to our readers. Finally, we are enabled to publish authoritative details concerning the Commission appointed by the Governor of the State to gather evidence dealing with recent events, and we give an account of the proceedings at the two first sessions of the Commission. The contributions by our own staff will also be found interesting.

THE first shock of the earthquake, as recorded by the Ewing seismograph at the observatory of the University of California, occurred at 5:12:38 on Wednesday morning, April 18. The earth wave traveled in a direction south-southeast to north-northwest. The principal shock came in two movements of maximum intensity, and it lasted two minutes. In violence, this earthquake far exceeded both that of 1868 and 1898. In each case the earth wave traveled in the same general direction. After the first great shock, several minor ones were felt. These came at 5.13, 5.25, 5.42, 5.59, 6.10, 6.27, 6.43, 6.47, 8.10, 8.15, 11.06 and 12.04. Those that were felt soon after eight o'clock were strong and were accompanied by a distinct rumbling noise. In the afternoon several shocks occurred at longer intervals and at 7.1 there was one, sharp and short, but enough to terrify people who were sitting at their evening meal after a long day of anxiety. At 3.17 on the 25th there was a tremor that caused discomfort to those members of our staff who, by that time, were busily occupied in preparing this issue for the press.

OAKLAND, being just across the Bay from San Francisco, and being peopled with a lot of generous folk, has received an immense crowd of refugees. The streets remind one of Cripple Creek or Leadville in the days of a boom, save that horsemen and rowdies are absent. An air of activity, and even of up-building, is given by the scaffolding and other temporary timbered structures necessary in making repairs to chimneys and to buildings that suffered from the earthquake. The tangle of wires and the accumulation of brick that marked the catastrophe were soon straightened or made to look tidy. By reason of the total destruction of every composing room and printing establishment in San Francisco, the daily papers all had to trespass on the courtesy of their contemporaries in Oakland, and as a consequence the number and frequency of special editions hawked by a multitude of small boys, gave Oakland the appearance of a town given up to a big political convention. Whatever the outward appearances, and they varied from grave to gay, from that which was tragic to that which was only amusing, there was, out of sight, in many hundred homes, a wondrous wealth of humanity and kindness that will long remain one of the compensating memories of a terrible event.

WE tender most sincere thanks to our advertisers for their valued support in promptly forwarding us new cuts and copy. The response to our telegraphic requests has been splendid and the episode will knit closer friendly relations as only misfortune, when shared and survived, can do. It is our hope to exhibit practical appreciation of this support, given when most needed, by making the MINING AND SCIENTIFIC PRESS a better paper than it has ever been; and the belief that this can be done is strengthened immensely by the fact that the members of our staff united to do their duty at a time when the sense of personal loss and discomfort was keen. It is a saying among the fraternity that a good mine must go through the baptism of a law-suit; few rich mining properties have escaped litigation in some form. Assuredly it is true that those who work together in an enterprise such as this journal, become united in purpose by such an experience as the recent unpleasantness, in a manner not to be effected even by a life-time of ordinary association.

IN regard to the relation between volcanoes and earthquakes, it is necessary to distinguish between those usually minor but frequent tremors, that are a part of eruptive activity and those occurrences which take place at a long distance from volcanic centers and are related to them only remotely by reason of both being manifestations of structural change within the crust of the earth. The volcano nearest to San Francisco that has been active during the human period is probably a cinder cone situated about ten miles from Lassen Peak in northern California, 170 miles from San Francisco. The forest that was buried by the scoria is still in evidence and it is estimated that the eruption took place within the last 300 years. Other extinct volcanoes are those of Mt. Shasta and several in the Kings River district. In the Mohave desert there are several perfectly preserved cones, and while they were active recently, from a geological standpoint, they became extinct in the beginning of human history.

DESPITE the effort of the Mexican authorities to stifle the truth concerning conditions in the Yaqui country, it is evident, from a letter that we publish on another page, that this part of Sonora is best avoided by mining men who do not care about prospecting the last hole of all. Our correspondent writes as one who is no tenderfoot, but, on the contrary, is familiar with mining in Mexico, and he does not give expression to such strong statements without full warrant for them. The news, last week, of the murder of Samuel Williams, the assayer of the Giroux Consolidated Mining Company, and two other members of the same party, comes as an unpleasant corroboration. The Mexican Government has slowly won the goodwill and respect of the United States, and it is hardly

to be believed that conditions such as exist in Sonora will be permitted to continue without investigation, followed by correction. In the meanwhile, the authorities on this side of the line will do well to attend to their duties. There is a pass 40 miles west of Nogales through which guns and ammunition find their way freely into the lawless region on the other side of the line. If one mentions the matter to a citizen of Tucson, he lifts his eyes to heaven with ingenuous astonishment. But such innocence is not in keeping with the air of the border, and it should not prevent an inquiry into a nefarious traffic, which is at the bottom of the atrocities that have disgraced the State of Sonora and discredited the government of Mexico.

AS seen from Berkeley, twelve miles across the Bay, the burning of San Francisco presented a succession of appearances. Within half an hour after the earthquake shock, a hump of dark smoke appeared over the City, growing during the succeeding hours until it rose through the quiet air like the clouds made by a volcano. When night came, the whole front of San Francisco was ablaze, the flames shooting upward at particular centers with the glowing discharge of a blast furnace; the light of the conflagration illumined the heavy clouds of smoke with a pink glow and the occasional rumble of a dynamite explosion gave the picture a suggestion of warfare. The next day (April 19) the clouds of smoke rolled skyward to a height of two miles, their lower layers dark, but the topmost billows sunlit and splendid. As evening came, a wind from the southwest blew the smoke over the Bay toward Mt. Tamalpais; the sun, like a red ball, threw a crimson light over the waters and there was more suggestion of horror than at any time. That night the big wooden houses in the residence portion were burning luridly, so that the flames rose high to heaven and glowing clouds pierced a starlit sky; the sight was one of desolating splendor. On the day following (April 20) the fire had pretty well exhausted itself and a dark murk of drifting smoke hid the ruins of the proud city of the Argonauts. But it was a quiet clear day, one of California's best; the sun that had set in a mist red as blood rose resplendent and full of life-giving promise. Already with the unconquered energy of a people that has developed a continent, the inhabitants began to talk of the re-building that was to give them another and a more beautiful San Francisco.

WE are profoundly grateful to our friends who by word, by letter and by deed, came to our support during a time of trial. The response to the telegraphic request for articles and material for publication has been such as to prove abundantly the faith we had in the innate generosity of our people. The pages of the Mining and Scientific Press during succeeding issues will demonstrate who helped and how effectively each one did it, by sending contributions of unusual interest. The editorial department rarely has dealings with the advertisers, but during the period of stress that followed the great conflagration, we were brought into closer touch with our clients on the business side of this enterprise, and it remains but to say that the evidence has been simply to prove, what we knew already, that men of the highest character and culture are now engaged in that essentially modern field of industrial activity which is termed advertising. Among so many proofs of generosity, we yet venture to single out one message as typical of a breadth of spirit that does honor to the name of American. Mr. G. W. Fuller, who represents the Cameron Pump, said to our New York manager: "We want our bills to run on just the same as if nothing had happened, even if you do not get out a paper for three months. We appreciate your effort in your advertiser's behalf and whatever you publish, if it has the single word 'Cameron' in it, will be fully satisfactory to us for months to come." We are reminded of a story told by Dr. Holland, chief of the Carnegie Museum at Pittsburg. On a certain pleasant occasion he informed us that the white hippopotamus was rare; in fact, there were only nine specimens in existence and one more, making the tenth, had been consigned to him and was then on the way from Africa. Well, we can state emphatically that 'white' men are not so scarce as white hippopotami, and as long as there are plenty of them, this Earth of ours will be a planet pleasant for residence purposes, despite such minor interruptions as are termed earthquakes.

It is fitting that we say a few words concerning the city that has given us shelter and a temporary place of business. At the beginning of the year Berkeley was a place of 40,000 inhabitants, the center of its life being the State University, whose beautiful oak glades and sloping lawns reach from the post-office to the foot of the Contra Costa hills. The group of buildings, of which three are of recent construction and one—the mining building—not yet finished, were uninjured by the earthquake and still stand in quiet repose facing the Golden Gate. Berkeley has always been a place of homes, beginning with the professors, instructors and students of the University itself, and followed by a number of professional and business men who had offices across the Bay in San Francisco. The facilities for going from the home to the office have been much improved during recent years, there being a double service, namely, the old suburban train and ferry service of the Southern Pacific Railroad and the new trolley line and ferries of the Key route. The convenience of living in a beautiful town situated on rising ground, overlooking the Bay, led to a great increase in the number of residents as soon as access to the City became easy. Now, of course, there will be a rapid accession in population and much of the business of San Francisco will take root here. Some of this will return to its former site when the City is re-built, but some of it will remain at Berkeley. While the Southern Pacific and the Santa Fe railroads both pass through the lower part of the town, the former has no station and the latter one that is not much used, but it is certain that recent events will lead to an immediate improvement in this regard. The accompanying map shows the position of the cities that have grown up around the Bay of San Francisco. At the beginning of 1906 the metropolis had a population of 400,000; Oakland came next with 90,000; Berkeley, 40,000; and Alameda, 20,000. Los Angeles, in the southern part of the State, has a population of 200,000, so that Berkeley is the fourth in size. It was named after Bishop Berkeley, to whom is credited the saying: "Westward the path of Empire takes its way." It was Charles Kingsley, in 'Westward Ho' who originated the saying, but whoever said it, the town of Berkeley is one of those that fulfilled it

The Earthquake

An experience such as that undergone a few hours ago by those who dwell on the shores of the Bay of San Francisco is apt to emphasize the fact that the earth we live on is still undergoing structural readjustment. At such times—or a little afterward, when chimneys have ceased falling and we have gathered wits somewhat perturbed by the unfamiliar sensations—we realize why the Greeks looked upon the Earth as a sentient being; the philosophers of the ancient world dwelt beside the Mediterranean, which from time immemorial has been the theatre of earthquakes, volcanoes and other manifestations of terrestrial unrest. It needs less poetry than fright to suggest the idea that like a giant disturbed old Earth is shaking himself awake, growling the while. As we write, at Berkeley, nearly four hours afterward, the clock, shaken to a standstill, marks 5.14 as the moment of the most severe shock. Across the Bay huge clouds of smoke, sunlit at the top like a splendid cumulus, indicate that San Francisco is afire. As we conjecture what may have happened there come two short shocks accompanied by a rumble; the tremor, but not the sound, being such as would be caused by a blast in a stope three or four hundred feet underground. A mine-blast makes a click, not a rumble, when heard at a distance. Meanwhile, like a severely critical building-inspector, Mr. Earthquake has broken every poorly constructed chimney and in our neighborhood the brick towers of a public institution have been shaken, one tower tumbling to the ground, while another has collapsed. People talk excitedly and compare experiences, the birds chatter in a flurried way and there is a general air of tension. But the sunlight is steady and warm, as if old Sol was too far away to be bothered by happenings on such a minor planet as ours.

Earthquakes may happen anywhere, they are not necessarily connected with volcanic eruptions and they are not confined to rocks of any particular age or character. It is true, however, that the agitation takes the form of waves the amplitude of which is increased when transmitted through yielding rock. Thus the Charleston disaster, in 1886, was intensified by the fact that the Southern city stands upon sand and other deposits soft enough to propagate vibrations. Several observers at Charleston watched waves as much as a foot high run across the surface, and these were met by another series going in an opposite direction, making complex movements which tended to loosen first one wall of a building and then another. Of 14,000 chimneys, not one hundred remained intact, but the number of fatalities was small, although the damage to property was estimated at five to six million dollars. But the worst catastrophe of the kind was that which befell Lisbon on November 1, 1755. This remains one of the great horrors of history. For several years preceding, the volcanoes of the Mediterranean had broken out with unusual violence and earthquakes had passed throughout Europe, without serious effect. Early in 1755 they became more frequent and on the night of October 31, Lisbon felt a slight shock. The next morning three severe vibrations were felt, the first of which lasted only six seconds but quite long enough to throw down practically every building in the city; Lisbon became a stone quarry. Shortly afterward there came a great sea wave and as it rolled toward the land, a huge fissure opened along the sea-front, engulfing a new marble dock which happened to be crowded with people who had rushed from under the falling houses to secure safety. They, the quay, and the boats moored to it all disappeared from view; the bottom of the bay was traversed by a chasm which closed over them, leaving no vestige behind. At a later date, soundings were made and these proved that there was 600 feet of water where once the quay had stood. Fires broke out in the city and destroyed what was left of it. It is estimated that 50,000 perished.

Charleston and Lisbon are occurrences concerning which we have reliable data, but the old records tell of many such catastrophes throughout human history. Antioch, though an inland city, has been the scene of an extraordinary repetition of earthquakes, the first recorded being that of 148 B.C. and the last in 1822. No place is immune from them and though they are common in volcanic regions, they may happen—possibly, from a different cause—in localities far removed from evident terrestrial disturbance.

To the miner they serve as an object lesson to bring home the fact that the faults and other ruptures which he sees underground, breaking his vein or dislocating his pay-streak, are due to causes which have not entirely ceased to exist. The earth is still proceeding through its cycle of change, and if the outward and visible signs of unrest appear to be infrequent, it is only because the duration of a man's life is so brief when compared to the time occupied in producing these geological effects, that he is apt to be unaware of them. The shocks felt by us today probably register a break in the earth's crust at some point—geologically—not far distant and the numerous minor tremors indicate a readjustment after the first break, which may be the culmination of a long period of strain among the strata above which our homes happen to be built. The earth in cooling is steadily shrinking and, like the skin of a dried apple, the outer rocky crust is contorted to the point of cracking, as it gradually adapts itself to a smaller interior. As the thickness of rock is ruptured, one side dropping relatively to the other, there is a shock which pulses through the overlying strata and reaches the surface in the form of earth-waves that prove too much for the structures built by man on the assumption of perpetual stability.

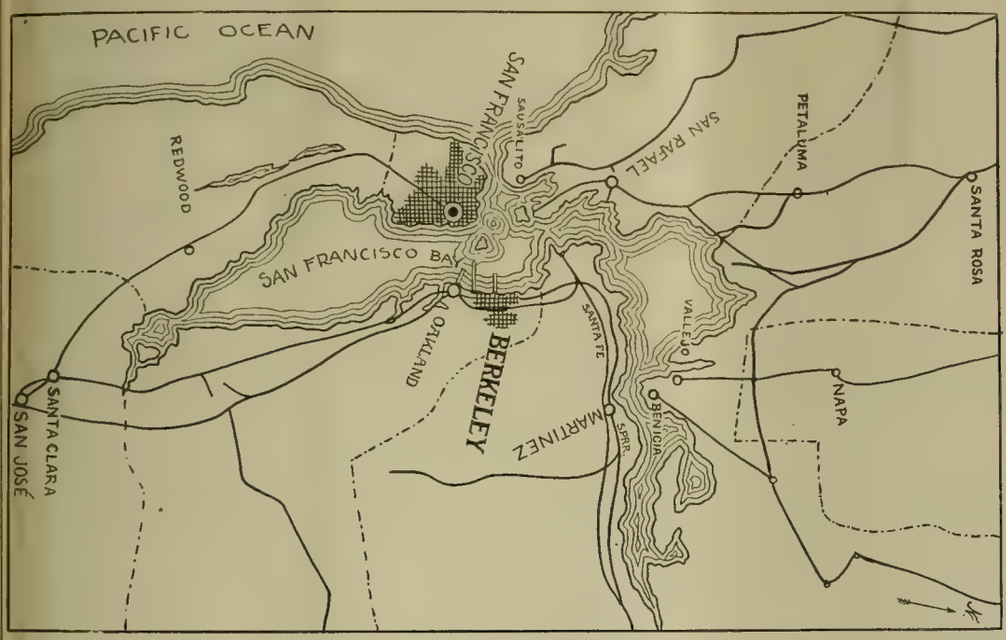
No part of the earth is safe from earthquakes; the place most free from tremors may be the scene of a shock the more severe for having a cumulative energy. The cause of these is only surmised, as due to a rupture within the crust, but the effects have been investigated and the movements measured so well as to indicate the center of the earth pulsation to be far beneath the surface. In the Charleston case, the shocks came from eight and twelve miles deep.

While volcanoes and earthquakes are manifestations that probably have a common origin in this shifting of the rocky integument of the planet we inhabit, it does not appear that earthquakes are necessarily and immediately associated with eruptive activity. The disasters at Charleston, in 1886; in the Mississippi Valley, between 1810 and 1813; at Antioch, on many occasions; and even at Lisbon, in 1755, all occurred at places several hundred miles distant from any volcanic vent. The active volcanoes nearest to San Francisco are those in Alaska.

In volcanic countries—in Central America, in New Zealand and in southern Europe—earth tremors are so frequent that the inhabitants have grown accustomed to them. The 'tremblors' preceding and accompanying a volcanic eruption take place at a comparatively shallow depth and they can be better diagnosed. An upwelling mass of lava, on reaching the ground-water, will provoke shocks, because the molten rock turns the water into super-heated steam, which expands with explosive violence when it penetrates cavities under-

ground; moreover the emanation of lava through a vent—frequently the crater of a volcano—will eventually leave a cavernous space which by the collapse of the overlying rock produces a settlement of the surface accompanied by vibrations, much in the same way, though on a different scale, as when the hanging wall of a stope falls in.

The relation between water and volcanic eruptions is one that is variously explained. The fact that volcances are found either near the sea or actually rising



THE BAY OF SAN FRANCISCO.

through the ocean floor, led to the theory that eruptive action is due to the penetration of sea water into cracks communicating with the molten rock, which, either as a sub-stratum or in isolated reservoirs, exists underneath the cold crust of the earth. The water was supposed to undergo tremendous expansion leading to violent escape, through vents which afterward allowed of an exit for the lava itself. But the best geological opinion holds nowadays that the volcanoes made the water, just as much as the water the volcanoes. The ocean marks an area of sedimentation, over which the detritus, worn away from the land and carried down by the rivers, is deposited. This accumulation of sediment proceeds until the thickness of material is measured by miles and until the pressure on the lower layers becomes so intense as to force out the water imprisoned in them. This water was carried down with the particles of sand and silt as they fell to the ocean floor and constitutes one-twentieth to one-fifth of the consolidated material. The successive layers present an impervious structure to the direct ascent of the water when it comes within the deep zone of high pressure and high temperature, so that an outlet is sought along the edge of the area of sedimentation, namely, along the rim of the oceanic basins. Hence centers of eruption become established along the coast.

The above notes dealing with the geologic causes underlying earthquakes, were written before there was any knowledge of the conflagration that was to destroy San Francisco. As the train and ferry service stopped early that morning, the writer employed the time of anxious waiting to prepare some notes, not anticipating any such catastrophe as supervened. The earthquake itself, which was destructive enough to all save wooden houses or a few of the most scientifically-built steel structures in the City, was also a cause for terror at Berkeley, but it damaged seriously only a few buildings. The vibration seemed to lessen eastward, so that Berkeley felt it less than Oakland, and Oakland less than the City itself or the minor towns on the San Francisco peninsula. In the redwood frame dwellings at Berkeley, one woke up suddenly on that fateful Wednesday morning to find the house shaking, amid violent creaking and cracking, so loud as to drown the crash of falling chimneys. Recognizing that it was an earthquake, one expected it to cease every moment, but after a movement of less violence, the horrible shaking began again, with greater intensity, until it seemed that the house must collapse bodily. To those who were unwilling observers of the phenomenon, it seemed as if the house were being shaken much as a terrier shakes a rat, with a final wrench that promised to make an end—but it was succeeded by a gradual decrease of the vibration. This feeling of a wrench, that is, of torsional strain, was emphasized in some of the taller buildings and it was due probably to the crossing of two sets of vibrations. In regard to other evidence, it is too early to collect accurate data. In San Francisco the street-car tracks on Market street retained their alignment fairly well, but the roadway was depressed fully four feet. Market street is paved with cobbles; where there was an asphalt pavement in the lower parts of the town below Montgomery street, the roadway was buckled so as to make tents, and in other spots there were depressions several feet below the normal level. Southward, along the San Francisco peninsula, the shock was particularly severe and, it is stated, actual fissures, five to seven feet wide, traversed the surface of the ground. Palo Alto felt this and, in consequence, the buildings of Stanford University succumbed. When a scientific investigation is made, as it should be made, either by the State or the proper department of the National Government, it will be found, we believe, that one fact stands out prominently, namely, that the earthquake was destructive in the City mainly from Montgomery street down—eastward—to the water-front. This area is 'made land'; the original shore followed an irregular line that coincides roughly with Montgomery street. By means of piles and filling, the City has encroached upon the shallows of the Bay. Visitors to San Francisco will have noticed how irregular was the level of the side-walk along the lower part of Market street; the pedestrian found the pavement three or four feet higher in front of one building than it was in front of the next. This was due to the City ordinance whereby the side-walk had been raised (to be followed later by a similar elevation of the level of the roadway) so as to secure greater depth for sewers, until they were below the basement floors. Many supposed that these irregularities marked the subsidence of the older buildings, but it was not so, as explained. There was plenty of evidence, however, among the older and poorly constructed buildings, of subsidence, but the irregular side-walk was no part of this testimony. The structures erected on plank were, in several cases, out of the perpendicular and others had sunk, while those built properly on piles were allright. The original fill was made of all sorts of stuff that was deposited to a depth of about ten feet upon the blue mud of the Bay, under which there is a layer of gray sand, seven to eight feet thick and very tenacious. This is succeeded by more mud. The piles not reaching hard-pan are gripped by such material so that in many cases it would be difficult to budge them with a two-ton hammer a month after driving. In the best practice, piles 70 feet long are used wherever hard-pan cannot be reached; this means a depth of 75 to 80 feet below the street, because it is necessary to get below the level of the tide. After the sea-wall of the new ferry building was made, the ground tended to shift less and it seemed that eventually it would become stationary, for the wall hindered the tide in penetrating the filling and placed an obstacle to creeping. The sea-wall made tidal action sluggish within this 'made land', and this did not affect the piles which still remained under water, but it did permit the plank to dry and therefore to rot, so that buildings on plank foundations have been sinking during recent years. This part of San Francisco felt the earthquake severely and in this respect the evidence agrees with that of Charleston. Similarly—although here the distance from the center of disturbance may be a factor—the lower alluvial flats of Oakland and Berkeley were seriously disturbed, while the parts of those cities that spread over the solid ground at the base of the Contra Costa hills felt the shock only slightly. It is apparent that the earth-wave caused by the rupture far below the surface, is propagated intensely in sand, alluvium, filling, made ground, or any other unfirm material. Build your house on a rock—or as near it as convenient—and if you find it necessary to live or to do business on yielding ground, see to it that the best engineering skill is employed, to the end that any natural obstacles may be surmounted by the application of scientific knowledge in construction.

FIRST NATIONAL BANK BUILDING, BERKELEY. OUR PRESENT QUARTERS.

Since the above was written we have been favored with Professor Leuschner's description of the records obtained by the seismograph. He also was prevented from going to the City on that Wednesday morning, although his anxiety to do so can be measured by the

fact that his wife was there, having been to the opera the night before and remaining with relatives until the next day. During the interval, before he could offer help to those on the other side, as he did most effectively later in the day, this scientific man busied himself with collecting data and making observations on the phenomena connected with the earthquake. It is interesting to note his quotation from the report on the earthquake of 1868. This, of course, we had not seen, when we made the remarks in a preceding paragraph and similarly Mr. Leuschner knew nothing of the damage done to buildings upon the filling below Montgomery street when he also referred to the danger incurred by structures erected on ground of this nature. There is room for comment here on the short memories of humankind. Here was an authority—E. S. Holden—who reported on the last serious earthquake forty years ago, and emphasized the danger of building "on the made land between Montgomery street and the Bay." Nevertheless, during the years since that report was published, people have continued to build there in disregard of the evidence that it was dangerous to do so without taking proper precautions. We emphasize these last four words, because as yet the evidence all goes to show that the greatest damage was done to buildings badly built or constructed on designs that ignored the principles of sound engineering. The amount of dishonest construction that escapes undetected in a big city is appalling and it is this that the earthquake, like a relentless inspector, exposes.

In this way the calamitous effects are a visitation or punishment for wrong-doing and if only those who were responsible were punished, there would be nothing to say. Speaking of a catastrophe such as this as a punishment, reminds one that in days gone-by the earthquake and conflagration that have destroyed San Francisco would have been hailed as an act of God. designed to wipe out a wicked and sinful community. While our people may be in a contrite mind and far from haughty at this time of disaster, they look upon the event as due to natural causes, the scientific reason for which they surmise vaguely. It is extraordinary to notice how much an elementary knowledge of geology has spread and how such knowledge has prevented the prevalence of superstitious fear or hysteric collapse. Whatever views people may hold regarding the general direction of the affairs of this Universe, even the most orthodox nowadays impute an earthquake to natural causes and this fact gives them a courage in adversity such as the ignorant and superstitious can rarely possess. Meanwhile, whatever little knowledge men may possess concerning the methods of the Great Architect of the Universe, is not incompatible with gratitude for preservation from a great peril and with hope for the future.

The Earthquake Commission

The Governor of California, with the approval of the National Government, has appointed a commission to make a scientific enquiry into the effects of the recent occurrence. The commission includes A. C Lawson and A. O. Leuschner of the University of California, G. K. Gilbert and Fielding Reid of the U. S. Geological Survey, John C. Branner of Stanford University, George Davidson, Charles Burkhalter and W. W. Campbell.

The commission met at the University of California on April 24. Professor A. C. Lawson was elected Chairman, and Professor A. O. Leuschner, Secretary. After a general discussion of the scope of the work to be undertaken, it was decided, in view of the alarming reports which had been circulated, to issue a statement to the effect:

1. That the times of earthquakes cannot be predicted, and that any predictions such as have been current during the last few days are unwarranted.

2. That severe earthquakes are generally followed by a number of minor shocks extending over several days or even weeks.

3. That the physiographic conditions in the Bay region are such as to preclude any serious damage from earthquake waves, popularly called tidal waves.

At its session next day, the commission prepared the following request for the transmission to it of any observations made by those who happened to be within the area of disturbance:

It is of importance that the citizens of the state of California co-operate with the State Earthquake Commission in its investigation of the recent seismic disturbance. For this purpose it is essential that the Commission receive, as soon as possible, information on any or all of the topics outlined below. All communications should be addressed to the State Earthquake Commission, University of California, Berkeley, California.

Give information on the following:

1. Post Office address; town, county, and State.

2. Place and date of observation.

3. Name and address of the observer, if other than the writer.

4. Give estimate of the intensity of the earthquake on the Rossi-Forel Scale. The Rossi-Forel Scale as amended by the Commission is as follows:

I. **Perceptible** only by delicate instruments.

II. **Very slight** shocks noticed by few persons at rest.

III. **Slight shock,** of which duration and direction was noted by a number of persons.

IV. **Moderate shock,** reported by persons in motion; shaking of movable objects; cracking of ceilings.

V. **Smart shock** generally felt; furniture shaken; some clocks stopped; some sleepers awakened.

VI. **Severe shock,** general awakening of sleepers; stopping of clocks; some window glass broken.

VII. **Violent shock,** overturning of loose objects; falling of plaster; striking of church bells; some chimneys fall.

VIII. Fall of chimneys; cracks in the walls of buildings.

IX. Partial or total destruction of some buildings.

X. Great disasters; overturning of rocks; fissures in the surface of the earth; mountain slides.

5. Give any facts that you can as to the directions the Earthquake Waves seemed to travel. Describe the character of the shock, whether a tremblor or an oscillatory motion, etc., and whether you yourself or others had any clear impression as to the direction in which it was moving, the facts on which this impression was based and whether people agreed as to the direction.

6. Give also any further particulars of interest, whether they are from observation or hearsay. If any changes occurred in the ground, such as depressions or elevations of the surface, fissures, emissions of sand or water, describe them fully. Character of damage to buildings. General direction in which walls, chimneys and columns in cemeteries were overthrown. Springs, wells and rivers are often notably affected, even by slight shocks, and any information in regard to such changes will be valuable.

7. State as exactly as possible the **time of commencement** and the **duration** of each shock.

The exact time of the beginning of a shock (to the nearest second), one of the most important of all observations, is difficult to get correctly, because of the great velocity with which the wave travels, and because the watch or clock must be immediately compared with a clock known to be keeping standard time. If several hours have elapsed before the comparing is made, another comparison should be made an hour later, in order to find whether your timepiece is gaining or losing. The observation cannot be regarded as a good one, unless it is stated that this has been done. Telegraph operators, railroad officials, watchmakers, etc., have especially good opportunities for answering this question correctly, and their cooperation is most earnestly solicited.

If a clock was stopped, give the exact time it indicated (and anything known, as how fast or how slow it was), its position, the direction in which it was facing, and the length of the pendulum.

8. If the shock was not felt in your neighborhood, although noticed at places not very far distant, do not fail to answer the first four questions, as negative reports are of great interest in defining the limits of the disturbed area, etc. State also the nearest point to your station where the shock was felt.

9. Name of writer.

Note.—In replying to these questions, they need not be repeated; but the answers should be **numbered** to correspond to the questions.

[We trust that any of our readers that can help the cause of science and the safety of our people, by transmitting such data as are requested by the Commission, will do so at once, while their memory is fresh. Editor.]

Many tests have been made to ascertain the conditions under which mixtures of air and fire damp become inflammable or explosive. Mixtures of fire damp and air, which are not ignitable by an open light, often ignite or become explosive on addition of a little coal dust, and mixtures which will not ignite on application of a flame of small intensity will do so when a flame of strong intensity is applied to them.—Compressed Air.

The Cause and Nature of Earthquakes

Written for the MINING AND SCIENTIFIC PRESS by G. K. GILBERT.

The scientific study of earthquakes has made great progress in the last few decades. On one hand there is substantial agreement among geologists as to the ways in which they originate, and on the other there is agreement among physicists as to the nature of the vibrations.

Earthquakes have two general sources. One group, known as tectonic are by-products of the subterranean forces and processes which make mountains and elevate and depress portions of the earth's surface. The other group, known as volcanic, are by-products of the movement of lavas from below upward. The tectonic are far the more numerous, and include all the important earthquakes that have been recorded in the United States.

In the formation of mountains and other great features of the earth, the rock masses are forced into new shapes. They are pulled, pushed, twisted and bent; so that strata, for example, which were originally flat, become inclined and curved. If the changes are sufficiently slow, the component particles of the rock readjust themselves gradually; but if the changes are comparatively rapid, the rocks are broken. Before fracture occurs there is elastic yielding, or 'strain'; that is, the rock is compressed or stretched or bent somewhat like a spring; and when its strength is at last overcome the dissevered parts recoil. This recoil is instantaneous, violent and powerful, and is of the nature of a jar. The jar is communicated to the surrounding rock, and is passed on from particle to particle in all directions. Each particle is moved from its original position and returns again, thus making an oscillation. Some conception of what takes place may be derived from the dropping of a pebble on the smooth surface of a pond. A wave is started which travels outward over the surface in all directions, so that at any instant it has the form of a circle. The motion within the earth is also called a wave—an elastic wave—but it travels up and down as well as horizontally and its form at any instant, instead of being circular, is spherical. Wherever this expanding sphere reaches the surface of the earth, there is an earthquake.

Volcanic earthquakes also are the surface manifestations of elastic waves, and many of them originate in the breaking of rock masses, but the initial jar is also given by explosions, and sometimes by the falling in of cavern roofs.

The fracture producing a tectonic earthquake may be a mere parting of the rock, but usually there is slipping along the fracture, constituting a fault. Some of the faults making earthquakes are visible at the surface. The Inyo county earthquake in 1872 was associated with a dislocation of several feet which can still be seen along the western margin of Owens valley. The greater number of fractures are not visible, but occur miles below the surface. The depth of the origin of the Charleston earthquake was estimated at 12 miles.

The fracture may be horizontal, or vertical or inclined, straight or curved. It may be miles in extent. It is not all made in the same instant but progressively, so that seconds or minutes may be consumed. The initial jar is thus distributed through space and time, with the result that the earthquake involves a very complicated movement. Some of the remoter readjustments appear also to consume much time, so that minor fractures take place at intervals after the main fracture—or, at least, that seems a rational interpretation of the fact that an important earthquake is followed by a long series of minor shocks ard tremors.

An earthquake is complex in yet another way. Elastic waves are of two kinds. In one kind the to-and-fro movement of the particles agrees in direction with the progress of the wave; in the other kind the particles move in a direction at right angles to the direction of wave progress. Every earth fracture starts both longitudinal and transverse waves, and the two kinds are started together, but it happens that they travel at different rates, so that at a distance from the origin a single initial jar may be represented by two distinct shocks. The behavior of the two waves is also qualified in an important way by the material traversed. The longitudinal wave may be transmitted by both solids and fluids, the transverse by elastic solids only. When a transverse wave encounters loose, incoherent material, such as sand, and especially when it meets wet alluvium, it is transformed into a wave of a different character, analogous to the surface waves of a body of water. It becomes visible as a surface undulation, its rate of progress is reduced, and its amplitude, or the

space through which the particle moves is greatly increased. It is for this reason that earthquakes are peculiarly destructive on alluvial lands.

Some Lessons From the Earthquake

Written for the MINING AND SCIENTIFIC PRESS by S. B. CHRISTY.

San Francisco, dear to the miners of '49, has been destroyed by fire many times before, but each time has sprung again to life more vigorous and beautiful than ever.

San Francisco, dear to the miners of today, has just passed through a new baptism of fire, but already she is shaking herself free from the ashes that cover her and will again hold the proud place she has won for herself more strongly, more grandly than ever. There is no fear for her future. The most permanent of human institutions are the great commercial centers. These are marked by Nature herself and nothing but the destruction of her noble harbor can prevent San Francisco from remaining the natural gateway for the commerce of the Pacific.

BERKELEY AS SEEN FROM THE HILLS, LOOKING TOWARD SAN FRANCISCO.

As the fires die out and the smoke clears away, some lessons of this great event stand out so boldly that it behooves us to profit by them for the future. In the first place, it is certain that with good foundations good designs and honest workmanship, the earthquake damage in San Francisco would have been as it was in Berkeley, merely nominal. It was poor design and construction that caused the losses. Buildings that stood on a sound foundation and were wisely planned and honestly constructed were practically unscathed by the earthquake. At the University of California, which stood upon the solid ground of the Berkeley hills, the seismograph showed an earth movement of about half an inch. But although actual records are missing there is no doubt that in alluvial soil, loose wet sand, mud, and other loose materials such as covered the lower parts of San Francisco, the earth motion was greater and probably of a different nature from the vibrations in solid rock. Nevertheless there stand in San Francisco, on made land along the water-front, a number of buildings upon deep pile foundations that suffered very little from the earthquake. There is no doubt that the modern steel-frame construction, when properly placed on a sufficient foundation and wisely planned and honestly built, is practically safe from earthquake shocks.

San Francisco contained a number of old fashioned structures, many hurriedly and cheaply built on insecure foundations; these were known to be unsafe and should have been condemned long ago. I saw many "concrete foundations" that had a shell of cement half an inch thick on the outside that were filled inside with loose sand. It is no wonder these gave way and undermined the structures they did not support. The earthquake was a stern exposer of sham and it ruthlessly searched out the work of ignorance, cupidity and graft. The City Hall had long been known as such a structure and it was seriously injured by the shock. But at the University of California, at Berkeley, the California Hall, and the Hearst Memorial Mining Building, designed and erected by the University architect, Mr. John Galen Howard, came out without a blemish. The total damage to all the buildings of the University of California (chiefly chimneys) can be covered by the sum of five hundred dollars.

In San Francisco the wide-spread ruin came from the fire. This too can be avoided in the future, if the lessons of this disaster are wisely utilized. Some of these causes of disaster exist in all modern towns and the like may happen anywhere. Modern cities are too much centralized; just as was the case in San Francisco. The electric power and light, the water and gas services were all at once disorganized. Telephone and telegraph lines failed to work at the time they were needed most. Numerous stations for wireless telegraphy should be established by every large city to meet just such contingencies.

The paralysis of the power plants stopped street-car service, both cable and electric, while the old horse-cars would still have been effective. The automobile service during the fire proved to be of incalculable value. With street-cars idle, telephones down, the automobiles went everywhere. They carried messages, wounded, supplies, dynamite—anything with certainty and dispatch.

The shoddy construction of the cheap flats and tenement houses south of Market street started fires all over this territory; and as the water supply was centralized, an accident to a part crippled the whole. As it was impossible to fight fire without water, the fire spread more and more until it had eaten up three-fourths of the city. The wreck of the water supply was another example of the excessive centralization of modern cities. Many square miles of buildings were destroyed simply because they depended on the general water supply which failed; but the United States Mint, though surrounded by fire, was saved, partly because it was honestly constructed, but also because it had its own artesian well for fire protection and an independent steam-pumping plant. If all other large buildings had been similarly equipped, the fire might easily have been checked.

In the absence of water, dynamite was resorted to. This was very effectively used by the army engineers, but many others who handled it, did not know how to apply it effectively and only spread the fire. Often when it was used, it was employed too timidly and was resorted to when it was too late. If the blocks in Chinatown between Kearny and Stockton had been promptly blown down Wednesday afternoon the entire residence district of the Western Addition might have been saved. A hundred California miners used to handling dynamite could have saved three-fourths of the burned district by intelligent and prompt blasting.

It was fortunate that the military and naval posts were so near, so numerous, and so efficient. The value of military discipline in an emergency was never more strongly demonstrated. It is difficult to imagine what would have happened in San Francisco during the dreadful nights that followed the fire, if it had not been for the presence of the regular troops. With a firm hand anarchy was suppressed every time it showed its head. Many a family owes its safety to the boys in blue. The militia and the cadets of the University of California also rendered very valuable service in protecting the lives and property of the citizens of San Francisco, Oakland and Berkeley. What these bodies lacked in experience was more than made good by superior intelligence and good-will. The University boys, under the able leadership of Captain Nance of the regular army, were hailed with cheers by the people as they marched to their stations, and petitions were circulated among the residents to protest against their removal when they were called back to Berkeley.

It would be a fatal mistake to rebuild on the old plan. San Francisco has a site of rare beauty. The Seven Hills of Rome are no more picturesque than hers. But the ugly streets which ascend the steep hillsides should be replaced by streets that closely follow the contours, on an easy grade, and the higher portion of the city should be laid out in terraces. The lower and flatter portion should be laid out in fire-districts covering not more than 160 acres each. These fire districts should be separated from each other by broad boulevards fully as wide as Van Ness avenue; and at each corner of every fire-district should be a park covering at least one block; so that at the corners of each of these fire-

districts there would be a park four blocks in area, serving as breathing places under ordinary conditions and as places of refuge in times of conflagration.

The space under the sidewalks should be no longer encroached upon by property owners, but should be open to tunnel-ways belonging to the city, for the reception of sewer, water and gas pipes, and for electric power and telephone lines, and should be under the control of the city government. This would make possible the constant inspection, repair, and a maintenance of these important arteries of the city's life, and would facilitate the easy distribution of power to the various residence and business centers; and would avoid forever the constant tearing up of the streets which has caused the destruction of the sewer and water lines by the earthquake.

Each fire-district should have its own independent source of water and power, so that its total destruction could not cripple the rest of the city. In the flatter portions devoted to business and manufacturing interests there exists an adequate supply of water easily reached for fire protection by artesian wells, and each large building should be forced to provide itself with such a supply, with proper fire service worked by an independent steam-pumping plant that would be available in cases of general conflagration. In the fire-districts and the hilly portions of the land there should be reservoirs always kept full of sea-water which can be easily supplied by properly distributed pumping stations. This could be utilized for flushing the sewers, for bathing as well as fire protection. These systems of water supply should be independent of the supply of drinking water.

The police, the military, and the fire departments ought to organize an efficient automobile service with numerous garage stations, supplied with small supplies of gasoline, which, with other inflammable substances, should be kept in underground chambers.

San Francisco should appoint a competent commission of architects and engineers to study, with the greatest care, the effects of the earthquake and the fire upon buildings having different types of foundations and modes of construction. This should be done at once, and a prompt and thorough investigation should be published immediately for the use of those who are intending to rebuild the new city, and the most stringent laws should be passed controlling the types of construction that shall go up in the new San Francisco. Every large building should be supplied with an underground vault similar to those of the banks for the protection of records and plans. Blue-prints of all the power lines, pipe lines, and sewers ought to be stored in such fire-proof vaults in more than one place. The wisdom of this procedure is demonstrated by the fact that such copies as were on file in the University Library at Berkeley have proved of great service. The value of large areas of park land, such as Golden Gate Park, the Panhandle, and the Presidio, has been clearly demonstrated. These areas should be increased rather than diminished. The Burnham plans certainly ought to be made the basis of the new city, although some changes may possibly now be made with advantage which were not possible before the fire.

These measures are absolutely necessary for the safety from destruction by fire, and while it might not be possible to condemn property for public use for the purpose of beautifying the city, it certainly is justifiable to do so as a measure of public safety, and it ought to be done intelligently and promptly. The success of a properly devised system of assessment of damages and benefits resulting from such changes was clearly shown at Baltimore. No city ever had an opportunity so great as San Francisco has at the present moment for utilizing the ideas of modern science and engineering skill.

No one who shared the terrors and uncertainties of the dreadful days and nights of the fire can have failed to be impressed by the noble courage of the men and women who suffered from the disaster. They met the dangers and accepted the losses with a courage worthy of the descendants of the men of '49. No one who witnessed these scenes can have any doubt as to the great future of San Francisco.

For fast cutting in drilling, the straight chisel-edged bit is recommended. This style of bit must be carefully tempered, as the cutting is mostly done by the sharp corners, which are likely to be chopped off if there is the slightest flaw. The hammer blows should be sharp and quick. In hard rock a somewhat rounded and rather blunt bit is more economical, though it will not, perhaps, cut so fast.

The Earthquake

Contributed to the MINING AND SCIENTIFIC PRESS by A. O. LEUSCHNER.

Students' Observatory, University of California, April 18, 1906.

An earthquake eclipsing in severity even that of October 21, 1868, occurred in San Francisco and the surrounding region early this morning. The earthquake came suddenly, without preliminary vibrations. The intensity of the first shock put the sensitive Ewing seismograph, of the Students' Observatory of the University of California at Berkeley, out of action, but a fairly complete record was obtained with the duplex instrument, of which the following is a preliminary account. The best record of the beginning of the heaviest shocks is furnished by the Standard clock of the Observatory which stopped at 5 hours, 12 minutes, 38 seconds Pacific Standard Time, while less severe shocks were recorded by Mr. S. Albrecht some 35 seconds earlier. The principal part of the earthquake came in two sections, the first series of vibrations lasting for about 40 seconds. The vibrations diminished considerably during the following ten seconds and then continued with renewed vigor for about 25 seconds more. But even at this writing, about 12 M., the disturbance has not as yet subsided, as slight shocks are being recorded at frequent intervals on the Ewing seismograph, which has been restored to working order. The principal direction of motion was from SSE to NNW. The remarkable feature of this earthquake, aside from its intensity, was its rotary motion. As seen from the record, the sum total of all displacements represents a very regular ellipse and some of the lines representing the earth's motion can be traced along the whole circumference.

The three severest earthquakes on record in this vicinity are those of October 21, 1868; March 30, 1898, and that of today. From their records an important conclusion may be drawn, which may be of value in constructing buildings in the future so as to guard as far as possible against destruction. The result of observation indicates that our heaviest shocks are in the direction SSE to NNW. In that respect the records of the three heaviest earthquakes agree entirely. But they have several other features in common. One of these is that while the displacements are large, the vibration period is comparatively slow, amounting to about one second in the last two big earthquakes. If today's shocks, as felt at Berkeley, had been instantaneous, inestimably more havoc would have been wrought among all kinds of buildings. The slowness of the vibration is the only redeeming feature in these calamities. The following account of the earthquake of October 21, 1868, as experienced in San Francisco, is taken from Professor E. S. Holden's 'Catalogue of Earthquakes, 1769 to 1897', and will serve to show the features it had in common with that of today. "The first shock was 7 h. 53½ m. A. M. Its direction was northerly and southerly. Its duration was 42 seconds. The second shock came at 9:23 A. M., lasting five seconds. Lighter and briefer tremors occurred at intervals of about half an hour, till 12.15 P.M. The first shock was most severely felt on the eastern side of the City, on the made land between Montgomery street and the Bay. On the solid land no serious damage was done to any well-constructed house. The Custom House was badly damaged. It was poorly constructed. As in 1865, a small crevasse was opened on Howard street, beyond Sixth. The greatest damage was done in a belt several hundred feet wide, running northwest and southeast, commencing at the Custom House and ending at the Folsom street wharf. The tall chimney of the United States Mint was damaged. The ferry steamer Contra Costa was near Angel Island and felt the shock strongly. Shocks were noted at 7.53; 8.10; 8.15; 8.45; 9.20; 9.30; 9.35; 10; 10.30; 11.05 A.M., and 2.58 P.M. Waves came 15 to 20 ft. further inland than usual. There were about thirty casualties in the 150,000 inhabitants. Five deaths occurred from falling walls, etc. Not a single well-built house on the solid land suffered materially, whether of brick, stone, or wood. Wooden houses suffered least."

By following the trace of the pen on the record, it can be seen that the first large motion of the earth was due west. It measures two inches. As the instrument multiplies 4.3 times, the actual displacement of the earth's crust or amplitude of the wave, was about one-half inch. This also corresponds to the average amplitude of the resultants in the direction SSE and NNW. Taking the average period as one second, the velocity of the earth-wave during the heavy shocks is found to be roughly two inches per second, by far the greatest ever observed on the Coast. Heavy masses on fairly smooth surfaces were observed to move as much as three inches. The times of the several shocks were carefully noted by Mr. Albrecht, Fellow in the Lick Observatory, now at the University as a graduate student of astronomy, until 9 hr. 26 m. A.M. After that records were taken by Dr. Crawford and Mr. Einarson with the Ewing seismograph. The last shocks recorded are mainly from east to west. Observers throughout California are requested to send their records to the Students' Observatory. The vertical component of the shocks was also of great intensity but of less frequency. The maximum shock measured in a vertical direction being 0.8 inch.

From Old Friends

NEW YORK, April 19, 1906.

Dear Mr. Rickard:

Your former associates on the staff of the Engineering and Mining Journal hear with deep regret of your probable loss through the catastrophe in San Francisco. We are without particulars as yet, but trust that the loss may not be so severe as our present information would indicate. In any event, we wish to express our sincerest sympathy, and to say that, if there is anything we can do at this distance to assist you, we will gladly render what service we can.

We hope also to hear that your home in Berkeley escaped, and that your family is well and uninjured.

Yours sincerely,

F. HOBART. R. McKEAN.
CHAS. S. PALMER. LILA L. DAWSON.
EDWARD K. JUDD. FRANK McHALE.
W. R. COCHRANE.

NEW YORK, April 19, 1905.

Dear Rickard:

You have my sympathy in this terrible calamity. hope your interests escaped without loss, but I fear not. Is there anything I can do to help? If so, call on me for any assistance that is in my power.

Yours sincerely,
W. R. INGALLS, Editor.

Friends in Need

The following interchange of telegrams speaks for itself:

1. DENVER, Colo., April 20, 1906.

T. A. Rickard, Berkeley, California.

You have our deepest sympathy in the fearful catastrophe that has befallen you. We offer to you all our facilities. We will reproduce your advertising pages of last week, edit and print ready for mail by the time you can get mailing list and instructions to Moore.

MINING REPORTER.

12:30 P. M. Delayed in transmission.

BERKELEY, Calif., April 23, 1906.

The Mining Reporter, Denver, Colorado.

Your friendly offer is cordially appreciated and will not be forgotten. We have made arrangements for our next issue. T. A. RICKARD.

---

2. DENVER, Colo., April 20, 1906.

T. A. Rickard, Berkeley, California.

Accept our sympathy, good wishes and command us if our plant or any part thereof will be of use to you.

THE DAILY MINING RECORD.

4:35 A. M. Delayed in transmission.

BERKELEY, Calif., April 25, 1906.

The Daily Mining Record, Denver, Colorado.

Your kind offer of help is keenly appreciated. We have made arrangements.

T. A. RICKARD.

The following letter has also been received:

Dear Mr. Rickard:

I wish to tender my sympathy, as well as that of my colleagues on 'The Mining World', for the great loss you have suffered from the appalling disaster in San Francisco. In a spirit of friendship we offer you our services, and hope you will not hesitate to solicit the help of a contemporary, 'The Mining World,' to rehabilitate the Mining and Scientific Press which has so long catered to the intellectual development of the mineral industry.

Assuring you again of our good will, and trusting courage will aid you to re-build on the ruins of a once beautiful city, we remain.

Yours very truly,
'The Mining World,'
G. S. SCOTT, Pres.

First Observations of the Catastrophe

Written for the MINING AND SCIENTIFIC PRESS by D'ARCY WEATHERBE.

These notes were made on Saturday, April 21. One who felt the shock in Berkeley at 5:15 a. m.—saw the results throughout Berkeley and Oakland between 8 a. m. and 3 p. m.; spent from 4 p. m. until 8 p. m. within the fire area and the business section of the doomed city of San Francisco on the first day of the disaster, and on the third traversed the wastes from the ferry to St. Mary's College on the Mission road, and from there to the water front end of Van Ness avenue, and back through the burned district to the ferry, should at least be aware of the prevailing conditions, in however poor a mood for description his experience might leave him. Not even the pen of a Zola could properly describe the impression received and stamped in a lasting manner on the mind of anyone of the odd half million people residing in the vicinity of San Francisco Bay on that fatal morning of April 18, 1906. In meager mechanical words, the general effects were a terror that left the recipient in a hopeless, mentally numbed state, followed by a physical nausea, the causes of which are akin to sea-sickness. It appears, too, that a common impression was that the end of the world had come. The reaction naturally was severe. The immediate and complete annihilation of the city by fire and the ensuing panic and consequent wild flight of the inhabitants in every direction was succeeded, as might be anticipated, by cases of starvation, together with looting, violence and demoniacal deeds perpetrated by the half crazed or debauched portion of a cosmopolitan community. Many instances of plundering the dead, wilful incendiarism, persistent selling of liquor, and violence to women were summarily punished by shooting on the spot, and in most instances the punishment was well deserved at such a crisis, though the example to some of the youths in soldier's clothes was bad, particularly as many of these were under the influence of liquor.

Men who are appointed to judge on the spot whether a fellow man merits death and then to act as summary executioner should be specially selected, and it is doubtful whether it were not better to altogether forego such method of punishment than to have law-abiding and respectable citizens butchered on the streets, as has been the case in San Francisco.

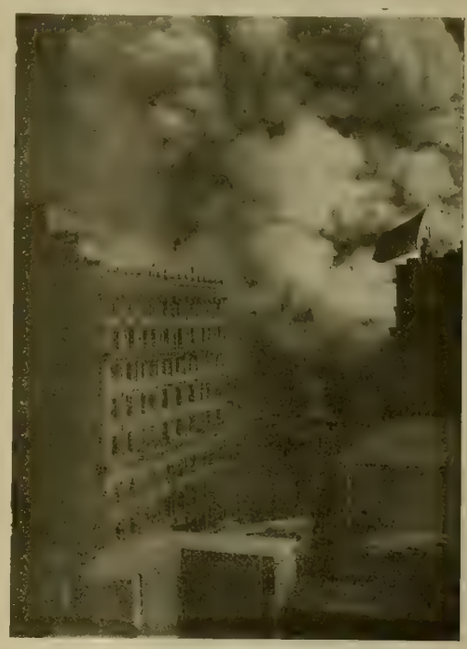
Scenes pitiful or ghastly were the rule at hundreds of points through the blazing city. The fire, which commenced south of Market street, near the water front, gained rapid headway and, almost unhindered by the helpless firemen, who were without water to combat the flames, it passed up town, licking up everything in its way, all the magnificent business structures, one by one succumbing to its fury. At the St. Francis hotel the main rotunda was crowded with the guests, who sat in the dusky twilight (no lights being available) with their hand baggage between their knees and waiting for they knew not what. This magnificent hostelry, which was thought, however, to be comparatively safe, was, seven hours later, completely gutted, the guests fleeing for their lives. With incredible swiftness the conflagration traversed the business portion of the city and seized with greedy tongues of flame upon the handsome residential and the other thickly populated districts. Governed only by the wind, it reached Van Ness avenue late on Thursday and followed north from Market street along the east side of Van Ness. Crossing this beautiful avenue, it wiped out a block on the west side and then, reluctant to give up its prey, turned northeast to meet the other fire which had previously devastated Nob, Telegraph and Russian Hills in its path northwestward toward the Golden Gate. Thus the entire area bounded by Market, Van Ness and the bay is laid waste; on the south side of the main artery—Market street—the devastated ground is roughly bounded by Dolores street on the west and by an irregular line following from about the corner of Dolores and Twentieth streets, down Twentieth to Kansas, and thence across to Twenty-fifth street and easterly by that street to the bay, and on the north by the water front.

The streets of Chinatown, which we passed through, were thronged by fully 3,000 Mongolians of all castes and ages. Some of the older men and women looked more like leprous animals than human beings, and many had probably not been out of their over-crowded dens for years. Their squalid effects, piled in every conceivable shape, impeded progress through the narrow streets, and passing through their district toward dusk we hastened our steps ferryward, traversing that disreputable locality known as the Barbary Coast. Here beasts in human shape in every stage of drunkenness, and delirious from stolen liquor taken from the wrecked saloons, shouted or sang in a perfect pandemonium. Within a few blocks the roar of the flames, the noises of constantly falling walls, and the dynamiting supplied a sufficiently hellish accompaniment to that orgy.

Refugees from the densely populated Mission district fled along the Mission road toward San Mateo, and the sights on this highway on Friday, the 20th, are never to be forgotten. An endless procession had left the city on Wednesday and Thursday with carts, buggies, motor cars and vehicles of every possible description, including hand carts and wheel barrows. Part of the throng camped wearily in the fields on the outskirts of the city, while others kept on toward the southern towns. On the fire burning itself out in this direction some of the refugees returned, and the scene on Friday morning was pitiful in the extreme. Under a blazing sky, the heat of the sun being intensified by the pall of smoke that hung over the city to the east, were seen old men and women helplessly and aimlessly carrying bundles hither and thither. Children with fevered faces and women with babes in arms, trudged through the dust, which lay nearly a foot deep on the road, and was raised in blinding clouds by the passing of wagons; this intensified a thirst already strong by reason of the unnatural conditions. Fortunately, water in this, as in most of the outlying suburbs, became available in reasonable amount, though even this was carefully husbanded. The fearful contingencies that may arise in these enforced camps are famine and disease, the latter spreading quickly on account of the necessarily unsanitary state of affairs. Similar conditions are the case at the Golden Gate Park and the Presidio, though here more facilities are provided for the comfort of the homeless people. In the streets bricks from the ruined structures are everywhere piled in the form of ovens, and meals are being cooked in the open. Crowds surround the occasional relief wagons that have gained access to the city. Flour is received from the cart in hats, in hands or in any available utensil, and is quickly converted into flapjacks or partially cooked dough. In the poorer districts the fact must be emphasized that more kindness and less greed were displayed than in those which could better afford generosity. In the Mission district almost every small grocery or food shop gave away gratis its entire stock. Even then an armed guard was necessary to preserve order. Men and women, with hands outstretched, thankfully took whatever was offered—tinned stuff of all kinds, meat, vegetables and fruit, and even bottles of sauce were thankfully received.

The handling of the conflagration by the fire department, the police and the military was probably, on the whole, fairly well done, though being from the first without water, it was a hopeless proposition. That it took as long as it did (five square miles laid practically flat in three days) was due entirely to the favorable condition of the atmosphere, which at first was without wind, and at a critical time changed so as to turn the flames back partly over the already consumed area. Dynamiting, unless done under skilful direction and carried out with experienced assistance, is practically useless and should be strongly condemned. Some of the methods used in the San Francisco fire did certainly not display either experience or even good judgment. In the district covered by frame houses from 75 to 150 lb of 40 or 50% powder was used. It was generally carried in bulk into the lowest floor of the building, placed in the center and set off with a foot and a half of fuse, taking about one minute to burn; the effect, in the cases that I witnessed, was almost entirely lateral, allowing the ruin to fall upon itself. So far so good. Fire in several cases started from the explosion, and it should have been carefully followed up by the little water available to prevent fire. Moreover, the strip to be dynamited in each case should have been decided upon long before the fire reached it, so that when the flames arrived a more or less barren patch would be presented. As it was, a handful of independent men without any head waited until the flames were within one or more buildings before exploding the edifice, the flying debris in some cases actually taking fire in the air. Several blocks were lost that might have been saved by taking the precaution to examine the contents of the building before blasting. In one case noted it contained explosives and spread the fire. It is, of course, easy for any one to criticize, though not so easy for the same people to have done better. My criticisms are meant in a friendly way. Moreover, we have no precedents of such magnitude as to serve for an example. It was, however, apparent to almost everybody that there was want of organization and system in the city. On the contrary, at Berkeley, the energy and systematized ar-

THE RUINS OF SAN FRANCISCO.



PALACE HOTEL BURNING.

rangements for relief will long stand as a shining example of prompt "first aid to the injured." Many lessons are to be drawn from the disaster and particularly from the effects of shock and fire on structures designed and built to resist both. It cannot be said that tall buildings will not resist shock if well built, for we have the case of the Chronicle and Call buildings. On the contrary, the Monadnock building, also a steel structure, though lower and of large base in comparison, was badly wrecked by the shock. However, the shearing strain on rivets and bolts must have been enormous, and it is probable even had there been no fire it would have been necessary to take down the majority of the large buildings for safety, even though apparently uninjured—as seen from the outside. However that may be, it is early to draw conclusions, and it is hoped that the subject may be gone into thoroughly and used as a text for some useful expressions of opinion.

Temporary Addresses of San Francisco Firms

BOSQUI, F. L., Ross, Cal.
BERTRAM HUNT, 750, 59th St., Oakland.
PACIFIC TANK CO., 518 Eleventh St., Oakland.
CHAS. C. MOORE & CO., 417, 14th St., Oakland.
HOLMES, GEO. L., 143 Santa Clara Ave., Oakland.
NATIONAL WOOD PIPE CO., 518, 11th St., Oakland.
UNION GAS ENGINE CO., 23rd Ave., East Oakland.
W. T. GARRATT CO., 2398 Broadway, San Francisco.
BOESCH LAMP CO., 1569 Grove St., San Francisco.
PRICE, GEO. W. PUMP CO., 105 Eighth St., Oakland.
PELTON WATER WHEEL CO., 1259 Alice St., Oakland.
CHROME STEEL WORKS, 1736 Walnut St., Berkeley.
BAKER & HAMILTON, 2701 Pavific Ave., San Francisco.
NATIONAL WOOD PIPE CO., 518 Eleventh St., Oakland.
REDWOOD MANUFACTURERS CO., 564 9th St., Oakland.
GOODYEAR RUBBER CO., 443 Fillmore St., San Francisco.
HARRON, RICKARD & McCONE, 2nd & Clay St., Oakland.
DEERE IMPLEMENT CO., 131 to 153 Kansas St., San Francisco.
HEALDS BUSINESS COLLEGE, 1451 Franklin St., San Francisco.
A. VAN DER NAILLEN, 5000 Telegraph Ave., Oakland. Alden P. O.
ALLIS-CHALMERS CO., care of E. B. & L. Stone. Broadway, Oakland.
JOSHUA HENDY MACHINE WORKS, 2323 Jackson St., San Francisco.
PARAFFINE PAINT CO., 405 to 403 Union Savings Bank Bdg., Oakland.
BYRON JACKSON MACHINE WORKS, 18 Telegraph Ave., Oakland.
DEWEY, STRONG & CO., 10 Bacon Block, 12th & Washington St., Oakland.
MOORE & SCOTT IRON WORKS, 405 Union Savings Bank Bldg., Oakland.
GEORGE E. DOW PUMPING ENGINE CO., 3116 Washington St., San Francisco.
WESTINGHOUSE ELECTRIC & MANUFACTURING CO., 1115 Broadway, Oakland.
CALIFORNIA HYDRAULIC ENGINEERING & SUPPLY CO., care of C. U. Martin, 1169 Jefferson St., Oakland.

A Good Gasket.—A very serviceable gasket may be made easily and cheaply by the following method: Ordinary heavy Manila wrapping paper should be cut out to the shape of the cylinder end by the ordinary method of cutting gaskets. This paper should then be soaked in boiled linseed oil for a few minutes and then have manganese dioxide applied to it with a paint brush, the linseed oil mixing with the manganese dioxide forms a black paint over the surface. The gasket should then be put on while wet and will form an exceedingly durable and efficient gasket for the cylinders of steam engines or air compressors.

AMONG the many creditable actions to be recorded is that of Baverstock & Staples, assayers at Los Angeles, who offer to make assays in behalf of their fellow-practitioners, the remittance in payment for this work to be credited to the San Francisco assayer who would have made the assays if his establishment had survived.

Personals

Henry Janin is in London.
E. McCormick is at Waldo, Oregon.
John A. Church is at Mexico City.
R. B. Lamb has returned to Hedley, B. C.
Edward Skewes is now at Sault Ste. Marie, Ontario.
C. L. Whittle. has returned to Boston from Costa Rica.
Edward L. Dufourcq has returned to New York from Peru.
Hal. W. Hardinge is at the Engineers' Club, New York.
Jas. W. Malcolmson is on a visit to London, from El Paso.
John B. Farish, of Denver, left San Francisco on April 16.
Albert R. Ledoux, of New York, is absent on a visit in Europe.
H. F. Poland, representing A. C. Burrage, of Boston, is at Butte.
Louis Janin has resigned as trustee of the State Mining Bureau.
O. H. Fairchild is examining mines in northwestern Washington.
W. J. Adams has a temporary office at 2902 Bush St., San Francisco.
H. H. Claudet has reached London, on a visit from Rossland, B. C.
J. Trowbridge Bailey sails on May 3 from New York to go to Brazil.
G. McM. Ross, of Copperopolis, California, is visiting his daughter at Berkeley.
W. L. Nasmyth and J. H. Nasmyth of Victoria, B. C., are in Sierra County, Cal.
T. G. Madgwick is on his way from London to the Orsk goldfield, in Siberia.
Horace A. Morse, president of the Sovereign Gold Mining Co., is at St. Louis.
Forbes Rickard has returned from Sonora, Mexico, and is on his way to Pittsburg.
Lee Glockner, of Cripple Creek, has gone to Wells, Nevada, to examine copper claims.
John M. Beckwith has resigned the management of the Nile Valley Co. and is in London.
Oscar Rohn, manager for the Pittsburg & Montana Co., is recovering from typhoid, at Butte.
Herbert A. Megraw is at the Bellevue Hotel, at High Point, North Carolina, until further notice.
J. J. Bennett, manager of the Kimberly mines, in Washington, has gone to Columbus, Ohio.
G. H. Rotherham, lately of Ymir, B. C., is making cyanide tests at the University of California.
Arthur Laughton has become manager for the Chicago & Mexico Mining Co., at Taxco, Mexico.
Anthony J. McMillan, managing director of Le Roi mine, has returned to Rossland from London.
G. H. Barnhart has ceased operating the Second Relief mine, near Nelson; he is now at Erie, B. C.
H. A. Shipman has gone to Ely, Nevada, on professional business. He will also visit the Tonopah and Goldfield districts before returning to Denver.
T. A. Jaggar, professor of geology in the Massachusetts Institute of Technology, has gone to Naples, to investigate the recent eruption of Vesuvius.

DURING THE EARTHQUAKE AND FIRE.

H. C. Roberts and Charles Butters were both absent, in Mexico.
Bertram Hunt had just returned to San Francisco from a professional trip.
E. W. Stebbins found shelter with his partner, Howard D. Smith, at Berkeley.
Arthur H. Halloran was at Reno, Nevada, at the time of the disaster. He is now at Tonopah.
E. B. Gage, manager of the Tombstone Consolidated, Arizona,, was in San Francisco on April 17.
J. W. Stearns passed through San Francisco on his way to Denver two days before the earthquake.
Austin H. Brown was at the Palace Hotel, on a visit from the Bully Hill mine, at Kennett, Cal.
Christopher R. Corning, of New York, was staying at the Pacific Union Club in San Francisco on April 17.
W. H. Radford lives on Broadway, a long way from the center of the city, therefore his home was uninjured by the fire.
Edward H. Benjamin, who was at 331 Pine St., San Francisco, has already opened an office at 903 Linden St., Oakland.
Albert Burch was in Idaho and he returned to San Francisco on receipt of the bad news. He went to Grass Valley on April 26.
H. P. Garthwaite was at the Palace Hotel, but he escaped with some belongings and is at the house of Charles Butters, at Berkeley.
F. L. Bosqui returned from Goldfield, Nevada, ten days before the event. He and his wife escaped to his father's house at Ross Valley.
George L. Holmes has opened an office temporarily at 143 Santa Clara Ave., Oakland. He has been to Oroville and Folsom this week.
Walter P. Jenney and Jas. W. Neill, who made headquarters at the Palace Hotel, were both absent, one in Nevada and the other in Utah.
H. deC. Richards was at Sacramento when the earthquake came, and he has returned to his quarters at the Cosmos Club, which was not burnt.
Sarat C. Rudra, of Calcutta is stated to have arrived in San Francisco just before the disaster. He had been examining mines in Sierra County, Cal.
Curtis H. Lindley, of 'Lindley on Mines,' lost his valuable library, but he and his family escaped unhurt, to the house of Henry Bratnober, at Oakland.
R. Gilman Brown and wife lived at the St. Dunstan, which was destroyed. They took refuge at the Ingleside Golf Club, on the outskirts of San Francisco.
At Oakland live Alfred von der Ropp, Henry Butters, Charles G. Yale, Arthur Goodall, Herbert Lang, J. R. Scupham, Mark L. Requa, Eugene Braden, Henry Bratnober.
F. W. Bradley and wife, who were living at the Palace hotel, pending the completion of their new house on Pacific Ave., found refuge with Mark L. Requa, at Oakland.
J. F. Halloran was at Washington, D. C., about to go to Europe. He proceeded at once to San Francisco, fearing his property was destroyed. Fortunately his house was outside the fire area.
R. Gilman Brown, Theodore J. Hoover, R. C. Turner and Thos. H. Leggett had offices at 310 Pine St. R. C. Turner had just moved his belongings and was at Tonopah, Nevada, at his new post as superintendent of the Tonopah mine. Thos. H. Leggett was in New York and Theodore J. Hoover in Mexico.
Among those belonging to the mining and metallurgical professions who live at Berkeley, and therefore escaped the worst effects of the disaster, are W. H. Storms, D'Arcy Weatherbe, R. B. Nickerson, P. George Gow, Albert Burch, Charles Butters, F. F. Thomas, F. C. Roberts, M. B. Newcomb, W. R. Thomas, N. C. Stines, W. H. Kett, Howard D. Smith, Alexander Burrell and William Sharwood.
Among those who had offices in San Francisco were: In the Crocker Building; Charles Butters, M. L. Requa. Albert Burch, A. Wartenweiler, H. C. Callahan, C. F. Nourse, Martin J. Heller, W. H. McClintock, F. W. Bradley, J. H. McKenzie, A. H. Ten Broeck, J. S. White, A. Scott, and J. C. Ralston; in the Mills Bdg. were: F. L Bosqui, A. P. Rogers, O. H. Balker, Homer Wilson, William S. Noyes, John M. Wright, and M. J. McDonald; in the Crossley Bdg. was L. C. Trent; in the Merchants' Exchange Bdg. was E. A. Stent; in the Rialto Bdg. were J. C. H. Ferguson, Geo. L. Holmes, O. B. Perry and E. H. Merrill. In the Nevada Block were Janin, Stebbins & Smith; also Ross B. Hoffman.

Oil and Gas in Kansas.—The Independence quadrangle is in the southeastern part of Kansas and includes an important part of the Kansas-Indian Territory oil and gas field. This field has an area of nearly 11,000 square miles and extends from Paola in eastern Kansas southwestward about 200 miles to Muscogee, Indian Territory and Cleveland, Oklahoma. The Independence quadrangle lies near the middle of this great belt. It embraces all of Montgomery county, the southern third of Wilson county and portions of adjoining counties. Its southern edge is the Kansas-Indian Territory boundary, while its eastern edge is approximately 47 miles west of the Kansas-Missouri line. The principal towns are Independence, Coffeyville, Cherryvale, Noedesha, Caney and Elk City. Independence, situated near the center of the quadrangle, is about 140 miles from Kansas City.

HYDROGEN does not unite with as large a number of elements as oxygen. At a higher temperature it displays a strong tendency to unite with oxygen, burning with an almost colorless and very hot flame to form water. This property serves for the identification of hydrogen gas.

IN Mexico a working partner must necessarily devote the whole of his time and attention to the business of the partnership, unless there be an express consent or an agreement to the contrary.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

The slow backward movement of abrupt rock faces due to weathering has been called the 'recession of cliffs,' a name appropriately descriptive of the process.

The slates of the Mariposa beds of the California gold belt have been referred to the Jurassic age owing to the appearance of casts of fossil aucella.

Miners can survey their own claims with considerable accuracy by using a common compass provided with sights and by taking care in making measurements.

Land in California more valuable for granite, limestone, marble or other structural stone, than for agricultural purposes may be located under the mining laws.

When estimating the $500 worth of work necessary to secure patent, any work done by former owners who had abandoned their claim cannot be considered as part of the expenditure.

Quicksilver is obtained on the Pacific coast from four minerals—cinnabar, metacinnabarite, native quicksilver and tiemannite (mercuric selenide). This latter occurs in Piute county, Utah.

The development of a mine is exploration. The stoping and working of a mine after it is developed is exploitation. A good maxim in mining is keep exploration well in advance of exploitation.

A normal fault is one in which the hanging wall has sunk relatively to the foot-wall, and a reverse or thrust fault is one in which the hanging wall side has moved upward relatively to the foot-wall.

The first dividend paid by the Calumet mine, of Michigan, was in August, 1870; the Hecla, then a separate property, paid its first dividend of $5 per share in December, 1869. Since that date these mines have paid in dividends $93,850,000.

Cost of fuel for engines: It will be convenient in estimating the amount of coal for hoisting engines, and the like, to use the following figures: Allow one-third of a ton of coal for each 10-h.p. per 10-hour shift. This rule holds good for most engines up to 80 horsepower.

Do not use laborers to do the work of masons or carpenters, nor should you require skilled workmen to do the work of laborers. A 20-cent man can lift as many pounds of wood or of stone as a 60-cent man. Plan to keep each class of man busy at his particular class of work.

Cylinders of engines and steam-drills are frequently cracked in cold weather by suddenly letting-in steam. To avoid this, open the drip-cocks and the cocks on the steam chest, and blow in steam for a few minutes to heat the cylinder before starting. A broken cylinder may delay work for a week or more.

The discovery of tin has been announced at many places throughout the West in recent years, but few of these reported discoveries are to be taken seriously. Those unfamiliar with tin ores are often led to believe garnet, iron ores and several heavy, dark minerals to be tinstone.

The greatest heat of air in the sun has probably never exceeded 145° F., nor the greatest cold lower than -74° F., at night. About 130° above and 40° below zero are the extremes in the United States east of the Mississippi, and 65° below zero in Montana, all at the common ground level. It is stated, however, that -81° has been observed in northeastern Siberia.

Theoretically a 1000-lb. stamp dropping 6 in. 100 times per minute, crushes 25% more ore than a stamp of 1000 pounds dropping 16 in. 30 times per minute, all other things being equal. It is claimed by those, in Colorado, that use the high, slow drop that the character of the ore demands greater time for amalgamation.

An anticlinal fold is one in which the strata dip in both directions from the crest of a fold. A synclinal fold is one in which the strata dip toward each other from opposite directions. A quaquaversal fold is one in which the strata dip away in all directions from the crest of an uplift. A monoclinal fold is one dipping in one direction only.

When using hanging bolts in shafts, use only large-sized iron washers. There is no economy in small washers. A 4 or 5-inch washer is far better than one 2½ inches in diameter, for should any downward tension exert itself the small washers will sink into the plates and there is sure to be a subsidence in the shaft-sets. Large washers will obviate this to a great extent.

Some of the loss of cyanide that occurs when gold and silver ores are treated by the cyanide process, may be traced to the presence of mineral acids and salts, such as ferrous sulphate and sulphuric acid, and to minerals soluble in cyanide solution. Such salts and acids are called 'cyanicides' or killers of the cyanide. To these must be added a certain percentage of waste in washing the tailing and to the loss by evaporation.

A company operating a mine or a reduction works, no matter how safe the work seems to be, must never neglect insurance of its men if it would secure itself against serious financial injury. There are insurance companies which will agree to assume liability for claims made by a workman or his heirs, except, that when a certain number of men are killed by a single accident, the company will have to stand part of the damages.

The laws of California require that a superintendent or manager of a mining company operating in this State under the laws of California make a weekly official report of the condition of the property, and progress of the work. This weekly report shall be accessible to the stockholders of the company at their principal place of business. Failure to make such report, or the filing of an untruthful report, is a misdemeanor and is a punishable offense.

The Egyptian obelisks are monoliths of great size—some of them nearly 80 ft. in length. That in Central Park, New York, is 68 ft. 5½ in. high, and 7 ft. 10½ in. by 7 ft. 5 in. at the base. A companion to this stands on the bank of the Thames in London. The Egyptian obelisks were usually made nine to ten times as high as they were broad at the base, and the width at the top never less than one-half nor more than three-fourths as great as the base.

Earthquake shocks are rarely felt severely underground, the principal effect being at the surface. The point of origin of the shock may be deep-seated—50 miles or more—but the wave motion is transmitted through the rock-mass without apparently disturbing the rocks until a point is reached near, or at, the surface when the result may be destructive. This is probably on the same principle that several balls may be suspended by strings in a straight line, the balls touching each other. If one of the balls at one end be drawn back, released and allowed to fall against its neighbor, the shock is communicated to each ball in the line successively until the end one is reached, when this will fly outward, the others remaining undisturbed in their position.

When shafts are sunk in rock firm enough to stand without timbering, the shaft may be divided into two or more compartments by means of timbers placed vertically above each other at stated distances, these timbers reaching from wall to wall of the shaft. To these may be secured the guides in vertical or steeply inclined shafts. In some inclined shafts, even these dividing timbers are dispensed with, only plates being placed on the foot-wall side to carry the tracks for skips or buckets, ladders, etc., and only such dividers as are necessary to support air, steam and water pipes.

There is often a vast difference in current reports concerning a mine that is being boomed for what can be made in a stock operation and one which is worked for what profit there is in it. A great deal of free advertising is sometimes given a mine, statements of high values being commonly made, in connection with great breadth of orebodies. During the last few months a large force of men has been reported engaged in development work and have succeeded in sinking a small shaft 60 feet in soft rock. In comparison with this is a gold mine in the Southwest which for months past has shipped large amounts of bullion monthly and yet its name in print is a rarity. These make a decided contrast.

The Court of Appeals of Colorado rendered a decision in a mine patent case, some time ago, in effect, as follows: In consideration of the sinking of a shaft in a mining claim, by certain persons, and obtaining a patent at their own expense, the owner of the claim agreed in writing to convey to them a stated interest in the claim, provided the patent was obtained by a certain date. The shaft was sunk in accordance with the agreement and the miners paid the claim-owner part of the expense of the patent, and notified him that they were ready to proceed in the matter of the patent at any time, but the owner advised delay, saying he would let them know when he would require the balance of the money. The court held that he thereby waived the condition that the patent must be obtained by a certain date, and could claim nothing for non-fulfilment; and also that, as they could not take out the patent, all they had to do was to furnish the money for the patent.

Shaft-timbers may be cheaply and quickly framed by use of templates, which make all framing uniform. Of the several systems or methods of framing shaft-timbers at the corners, the overlap joint is simple and easily made. This overlap is employed in vertical shafts only and is framed by cutting out one-half the thickness each of the wall-plate and end-plate to a width equalling the width of the timber. The upper half of the wall-plate is cut out and the lower half of the end-plate is removed. The wall-plates are first placed in position as nearly as may be, being swung on hanging bolts. When both timbers are on the bolts, a gauge is slipped in at each end, by means of which the timbers are adjusted at the proper distance from each other, when they may be secured in that position by tacking a piece of lagging on top of the plates near each end. The end-plates are then dropped in and the set wedged to place, which is determined by a plumb-line in each corner, suspended from sets above which are known to be in line. The lines should take in not less than three sets in height. If four lines are not used, the sets are likely to be wedged out of line. Lining up sets is a particular job requiring care, patience and good judgment. It pays to do shaft work well, and good enough is only good enough when it can be no better. A slight departure from the true line is scarcely noticeable at first; but, as set after set is put in place with equal carelessness, it soon develops a shaft which is not a credit to anyone. In inclined shafts a dovetailed notch is cut near each end of the wall-plates and a corresponding tenon cut on the end-plate. The timbers are placed in the same manner as explained above. Timbers framed in this way may also be used in vertical shafts. This latter method requires less timber. Where absolute rigidity is required in shaft-sets, it is good practice to put posts at each corner, and in large shafts also at the center, or opposite the dividers. When the shaft is being lagged have the post of the same size as the plates, or, at least, one dimension of the same size. If 10 by 12-inch plates are used, they should be put in with the 12-inch face upward. The posts should be 8 or 10 by 12, the outside faces being placed flush with the outside of the plates. This will make the posts line up with the lagging, and no lagging need be put behind the posts. The amount of timber required is less, and the saving of time is an item of even greater importance.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

THE ASSAY OF CYANIDE SOLUTIONS

The Editor:

Sir —Mr. William Magenau, in your issue of April 14, mentions some modifications in the method of Mr. Alfred Chiddey described in The Engineering and Mining Journal of March 28, 1903. I have used the same method with somewhat different modifications, getting accurate results but consuming a much longer time. The method, as modified, is as follows:

Take 100 c.c. of the solution to be assayed, add 7 c.c. of a 10% lead acetate solution, then add one gram of zinc shavings and place on the hot plate. Heat, but not to boiling, until the lead has gathered around the pieces of zinc. This usually takes about 25 minutes. This precipitation being complete, 20 c.c. concentrated HCl is added and the heating continued until all effervescence has stopped. The lead is then in such a spongy condition, that by the aid of a flattened glass rod, it can be pressed into a cake and the clear solution poured off. Wash the lead twice and then with the fingers press it into a compact mass, drop in a lead-foil funnel, leaving a vent for escape of the steam, place in a hot cupel and proceed as in an ordinary cupellation. This latter operation consumes from 25 to 35 minutes; the lead button is ready for cupellation in about one hour.

I have used this on solutions varying in strength from 0.01% KCN to 0.4% KCN and in value from 0.04 to 3 oz. gold per ton. I have also used it for the assay of silver solutions, but when they are rich the results are lower than those obtained by the evaporation in lead boats.

The secret of keeping the lead from breaking up, is not to allow the solution to come to a boil at any state of the procedure.

NORMAN C. STINES.

Berkeley, Cal., April 23, 1906.

THE TREATMENT OF DESERT ORES

The Editor:

Sir—Referring to Mr. Bosqui's recent article on this subject, athough in the typical oxidized gold ore of the desert regions of Nevada and California the gold is free, it is so extremely fine and flaky that it does not readily amalgamate, but only yields a comparatively small percentage, and treatment by cyanide is necessary. The present fashion of putting in stamp mills and amalgamating arrangements followed by a cyanide annex evidently is due solely to the "compelling power of custom," and not to any proof that this is the best method of treating such ores. To me this looks like attempting to make the ore suit the process, instead of suiting the process to the ore.

The wet crushing followed by cyanidation does not allow the treatment by either amalgamation or cyanide to be done under the best conditions. It often happens, especially when inside amalgamating plates are used, that particles of amalgam become detached and are carried with the pulp to the leaching vats. The gold in this amalgam is not completely recovered in the cyanide treatment, because its solution is very slow indeed. In fact, in practice none of it is got. It can only be recovered after the tailing has been allowed to weather for a sufficient time to oxidize all the mercury to mercuric oxide—this and the gold being readily soluble.

Further, the sand and slime are received in the cyanide department in the worst possible condition for treatment, as they contain a large excess of moisture which has to be displaced by cyanide solution. This occasions a mechanical loss of cyanide and the dissolution of the gold is much slower than if the material had been dry when brought in contact with the cyanide solution.

Many of these ores also contain large amounts of hydrated silicate minerals, such as clay and talc, which have the property of becoming plastic when worked with water, yielding slime which is difficult (and requiring an expensive equipment) to treat. On the other hand in the dry-crushing direct-cyanide method, the material is got in the best condition for treatment by cyanide. As all the interstitial spaces are filled with air, the extraction of the gold is rapid. In the drying also, the hydrated silicate minerals are de-hydrated and lose the property of becoming plastic; therefore the subsequent leaching is much more cheaply and efficiently done. Further, if the ore contains gold too coarse to be dissolved in the time of treatment allowable, the tailing can be easily passed over some amalgamating device and the gold (having been cleaned by the cyanide) will amalgamate readily.

The use of stamp-mills crushing in cyanide solution may be satisfactory in the case of hard clean ores, but with soft oxidized ore, dry crushing is undoubtedly the best. The cost of installation of a dry-crushing direct-cyanide plant is less than that of a stamp-mill and cyanide annex and will be found to yield a higher profit in the majority of cases. As the majority of these oxidized ores give a practically complete extraction by direct cyanide treatment, what is the advantage of using both amalgamation and cyanide to recover the same value? The removal of a portion of the gold as amalgam does not reduce the cost of cyaniding the material appreciably. The consumption of cyanide due to the gold content is negligible.

In many cases these surface desert ores are porous, so that very fine crushing is not needed and a straight leaching plant can be installed at a much smaller cost than a stamp-mill and cyanide annex of the same capacity. These oxidized surface ores are called "free milling," evidently just because they show free gold on panning. This is not correct. A "free milling ore" is one that yields a large proportion of its gold to plain stamp-mill amalgamation. In no instance will these 'free' desert ores yield any large proportion of their gold to amalgamation but in the majority of cases the gold is completely soluble in cyanide.

BERTRAM HUNT.

San Francisco, April 17, 1906.

THE YAQUI COUNTRY

The Editor:

Sir—From the standpoint of a mining engineer who has been into other parts of the Yaqui Territory before, and who has just now ridden over two hundred and thirty miles of country lying in and about the hot-bed of these Indians, and also speaking with the authority of one who has recently discussed the Yaqui question with those in high authority—with prominent citizens of Mexico as well as with the peasantry in the disturbed sections—I am prompted to ask for space in your columns to protest against what, in my opinion, is more ignominious than the scandal that attaches to the question in general; that is, that it should have been possible to circulate a proclamation denying the Yaqui danger, which proclamation is manifestly designed to attribute to bandits such depredations as have been perpetrated, and at the same time intended to minimize the danger of travel in Sonora in respect of possible Yaqui attacks.

It is scarcely to be believed that such a proclamation as was in fact addressed to the Department of Fomento, City of Mexico, that is, to Government headquarters, and found the willing or unwilling signatures, as the case may be, of more than one hundred names, including merchants of Hermosillo, Guaymas and Magdalena, native and foreign alike. These were the names of business men, mine owners, mine managers, mine superintendents, bankers, storekeepers, etc., including even the name of the American consul of at least one of the towns named. I ask the question, does force of circumstances justify this written outrage on public credulity?

Among the names of those who signed this malicious document was that of Don Pedro Meza, presidente of the little mining town of La Dura; he has paid for this the penalty of death, even though he carried an escort of forty soldiers, a fact which in itself gave the lie to the assertion that the Yaqui danger was exaggerated, if it existed at all.

A Los Angeles newspaper of March 26 comes out with an article under the head line, "Story of Massacre Fully Confirmed," and in describing the assassination and butchery of Don Pedro Meza, his wife and three grown girls, Mr. Hoff and his wife, this newspaper indulges in a vivid, distorted and false version of the circumstances of this horrible outrage.

It was my chance to come upon the scene of the ambush two days after its occurrence and to look over, and take photographs of, seven partly burned bodies of the Yaqui dead, which numbered nine altogether, and I saw besides from fifteen to twenty dead horses that marked the direction of the fight. A day later we crossed the trail of this same band of one hundred and fifty Yaquis, who were carrying their wounded, as we knew from a quilt which they had discarded, and from blood stains. The signs at this time were very fresh and indicated, what was corroborated afterwards, that we were very close to the band that had killed Meza and Hoff and their families.

What we saw here, taken in conjunction with the fact that seven men and women traveling in the Meza party were killed and five of Meza's personal servants—constituting his guard—one officer in command and two soldiers of an escort originally forty strong, proclaims only too plainly the horrible truth. No ground is left for dramatic journalism under these circumstances, when the passengers are assassinated and the escort is saved. There is but little doubt that the battle belonged to those who did not survive to tell the story of their brave part in this inglorious episode.

The party with which I was traveling went out under the direction of Mr. George M. Ryall, of New York City, who is a concessionaire of some of the best mining territory contained within the Yaqui zone. It included, in all, five Americans under escort of eighteen rurales and two officers of the rank of lieutenant. In coming upon the scene of the ambush below Otate pass, east of Suaqui Grande, we had followed for two hours the trail of the Yaqui band going in the same direction and had noted the single mule-prints of the animal which was ridden by their chief.

These facts speak for themselves, but that is not enough. I raise my single voice in unwavering protest against the many who in the signing of the shameful proclamation have signed away the lives of tens, and probably hundreds, of men and defenceless women who dare to venture outside the walls of their little towns upon errands that make their travel imperative. It is true that there have been American citizens murdered in ambush; and there will be more to swell the list if they go out into the Yaqui country trusting to the misrepresentations that have been made to the Mexican Government by mining and mercantile interests, and even by their fellow countrymen who have wantonly signed the lying document and cleverly worded death trap that has been so carefully prepared by some of those in authority. If I have the qualifications to enable me to make a statement of the real condition of things as I have seen them, I have also the courage to declare against American citizens who are weak enough to lend their names to such outrageous purposes.

Looking a little closer toward home, there comes an official order from Washington, D. C., according to which American citizens going in and out of the Yaqui infested zone do so at their own risk and peril. I believe that I voice the sentiment of other Americans when I ask, "Is that all the protection the United States citizen is to expect from his Government?" and "Are not these same United States authorities aware that there is virtually no ammunition to be had in the larger towns of the State of Sonora in the region of the Indian trouble?" and further, "Are not the Yaquis getting their rifles and ammunition from Tucson and Nogales and other points about, and north, of the United States frontier?"

In answering such interrogatories our Government will have to admit that there is no restriction placed upon the sale of arms and ammunition to the Yaqui people, and will have to face the fact that our frontier habitations support many Indians who are in constant communication with their fellows in the field. That they are being aided in defense of lands which they claim by right of possession, is poor consolation when one runs the risk of being ambushed at every turn in the road. Many Yaquis are still employed by American interests in mines near the frontier.

The daily importation of ammunition* along the border line, the harboring of Yaquis on the American side, and the employment of Yaqui labor by American interests on the Mexican side, can be verified in each respect by anyone who wishes to inform himself of the Yaqui question, and if he be in the mining profession and he thinks upon the ambush of mining men whom he may have personally known, he may well stop to ponder as to how much the United States Government is doing to protect the lives of its citizens when engaged in developing the mining interests of Sonora before he looks across the line to criticize the Government of a sister Republic. He will find slim consolation either way.

I have talked with the Mexican Government scouts, whose duty it is to post the army authorities on the disposition, movement and numbers of the several

*The Yaqui generally carries the discarded arm of the Mexican army, a 45-90 Remington single-fire rifle, with peep sight; the guns that they are importing are Winchester 30-30's and other modern weapons.

bands of Indians that constitute the Yaqui people to-day. These scouts can, and do, furnish the information required, but in the meantime fatalities are frequently reported in the form of the ambushing of a stage or of a coach party, or of Mexican families, or of the killing of a foreign traveler—sometimes traveling with an escort and sometimes without. It has all happened before and it will happen again. In the course of time it becomes the tearful gossip of a mourning, poverty-stricken people, but the news is never published and information of it is quickly suppressed. The newspapers are under the ban. On the other hand, there is the deserted ranch and houses, roads unused, wells abandoned and cattle left to run wild with two-year-olds unbranded. That is what the traveler will see to-day in going from La Colorado to Tecoripa, to San Javier, to La Dura, to Suaqui Grande and back again. As it is true of this section, it is likely to be equally true of the country in the vicinity, whether it be more infested or less infested, and if there be any reader who questions such description as I have given of the territory within the bounds named, let him go a few miles to the north and northwest, to Cobachi mountain and Mazatan mountain, and he will find something still more interesting.

My final word to professional friends is to advise them to stay out of the Yaqui country until there is some better assurance of security of travel and safety to life than anything that exists to-day, whether going under escort or otherwise.

Under conditions involving so many conflicting statements concerning these Indian troubles, the man who has business that takes him into the Yaqui country has been in the same position as the man who is cautiously watching the questionable maneuvers of a dog that barks and wags his tail at the same time. He is in no position to know which end of the dog to believe. To mining engineers who will take this word of warning I say that the tail of this beast wags deceitfully.

El Paso, Texas, April 11, 1906.

FORBES RICKARD.

BLAST VS. REVERBERATORY FURNACES.

The Editor:

Sir—In reply to the first question, I would say that the choice of furnace should depend on the fineness of the ore to be smelted. Concentrate finer than 16-mesh makes too much flue-dust to be profitably smelted in a blast furnace, and should, therefore, be smelted in reverberatories, after roasting, if they are sulphides and require roasting.

2. In certain localities where coking coal is not obtainable, and inferior light bituminous coal, lignite, or wood are cheap, the reverberatory might be preferable on coarse material.

3. The fluxes necessary might have a strong bearing on the selection of the furnace. Other things being equal, less flux is necessary for a reverberatory furnace running on a silicious charge than is necessary to smelt the same charge in a blast furnace. A reverberatory can get along with less copper than a blast furnace on a silicious charge, while a blast furnace can carry a more basic slag than a reverberatory, and requires less flux, for the reason that a basic slag will cut out the hearth of a silica-lined reverberatory and cause great expense for repairs, which would not be the case with a water-jacketted blast furnace. A reverberatory lined with magnesite brick would not be subject to the same weakness when run on a basic slag, because magnesite brick has a wonderful resisting power to all kinds of corrosives. To give a comparison of the relative value of magnesite, chromite, water-jackets, ground quartzite and clay, I will digress and state the result of some experiments which I have made on these materials.

The matte-tap on the 9-ft. diam. settlers in use at the plant of the Mond Nickel Company in connection with the 44 by 120 in. blast furnaces gave out rapidly, and caused many runaways, with accompanying explosions. It became of great importance to find a tap-jacket that would withstand the action of the stream of 25% copper-nickel matte when tapped into the converters. The water-jacketed tap-jackets, whether made of cast iron, with pipe-coil, or of copper or bronze, were quickly destroyed, and were the cause of explosions that threatened the lives of the furnace-men when making a stop. The stream of matte could not be regulated closely enough, and the converter-charges were irregular in size as a consequence.

I had a block made of chromite with the proper-size hole to tap through, and put it in place of the tap-jacket. It lasted about one week, which was about twice as long as a water-jacket under similar running conditions. Then a similar block was made of magnesite, and it has been in use for two months under a much greater flow of matte, and is apparently as good as when first put in. It will be understood that a settler can be run without any other tap-jacket than a clay breast, if the speed of smelting is regulated so that the radiation from the settler will cause a skull of sufficient thickness to act as a jacket, but if the furnace is driven rapidly by increasing the blast, the conditions are quickly changed, and the matte-tap becomes unmanageable and dangerous. The matte-tap in this case becomes the limiting agent of smelting operations, and while it might appear to be a very small thing to cause a plant to slow down, that is exactly what it did.

Graphite electrodes made by the International Acheson Graphite Company of Niagara Falls were cut into blocks, drilled for tap-hole, and used in place of the chromite blocks; they gave slightly better results. There is, however, a considerable amount of FeO or Fe_2O_3 in all matte, and the oxide acted on the carbon at high temperatures and destroyed the blocks, causing runaways of several tons of matte, with accompanying pyrotechnics and detonations such as the Japs never heard at Port Arthur.

The magnesite tap-jacket therefore has come to stay, and while it may not be a feature of as great importance in copper smelting as it is in our case, on account of the extraordinary corrosive action of nickel mattes on tap-jackets, still it is one that is worth the attention of all furnacemen. Magnesite brick was also used as a dam in the furnace-spout to trap the blast, and the stream of matte and slag has been flowing steadily over it for two months at the rate of 300 tons per day without cutting it out or making it necessary to renew it. This I consider the most severe test that any refractory material can be put to.

Magnesite brick is also employed as lining for softening furnaces used for refining lead, exposed to the action of lead oxide at high temperature, and while I have no information about the result, I am satisfied that they are superior to any other material for any purpose of that nature.

At the Pittsburg and Montana Copper Company's works, near Butte, Mr. W. A. Heywood reports remarkable results in lining copper converters with magnesite brick 9 in. thick, feeding in all the silica necessary for slag formation while the converter is in action. At last accounts, one such lining had been in continuous operation since October 17 1905 and showed no appreciable wear except near the tuyeres, where it had been repaired about once each month. This is the most remarkable result obtained in copper converting, and I proceeded at once to try it on copper-nickel matte and regret to state that the result was a failure, which I ascribe to the presence of the nickel. In copper converting, the entering blast oxidizes sulphur, iron and some copper. The copper oxide is quickly reduced to copper or copper sulphide. The iron oxide unites with silica of the lining to form a fusible slag, which rises away from the tuyeres, and the SO_2 gas escapes from the nose of the converter. When the matte contains nickel, the nickel oxide formed is not reduced in the same way as copper oxide, and there being no silica at the tuyeres (if the lining is magnesite) for the nickel oxide to combine with, it is chilled by the entering blast and closes the tuyere. The result is that the blast will not enter without incessant punching of the tuyeres, and then much more slowly and at higher pressure than is the case with a silica-lined converter on the same grade of matte. The net result was that while we were able to convert some matte with the use of a magnesite lining, the capacity of the plant was so reduced that the experiment was abandoned after a two weeks' trial on twenty-five charges.

4. Returning to the question of the blast furnace as against the reverberatory, I would say that each in its particular sphere is suited to do certain work, and it is bad practice and shows poor judgment to try to make either cover the entire field. For example, suppose the charge is a lead concentrate, the simple fact of it being a concentrate would not justify anyone in trying to smelt this material in a reverberatory, although galena used to be reduced to lead in a crude way in a reverberatory. I think that method has been practically discarded. The comparative cost will depend entirely on local conditions of fuel supply, character of ore, size of furnaces, and the skill and ability of the operatives, and cannot be stated until all of these conditions are known.

The relative cost of installation per ton of furnace capacity would appear to be lower in case of the blast furnace. The reverberatory plant will require more space, probably twice as much, for the same tonnage.

5. This question is too general, and, as above stated, the answer depends on local conditions. The blast furnace will require more power. The reverberatory may, or may not, require more labor, depending on whether the charges are smelted from hot calcine or cold ore, and the fuel question depends on the same conditions.

6. Regarding the comparative amount of capital invested in plants of equal capacity, it is my opinion that for small plants they would be about equal, but for plants of large capacity the blast-furnace plant would cost much less, probably 50% in case of a plant of 1000 tons per day.

7. The limiting necessity regarding fuel with the reverberatory is a long-flaming coal or wood with as little ash as possible; and for the blast furnace, coke that is strong and as low in ash as can be produced out of the coal from which it is made.

8. The comparative slag-loss will depend upon the grade of matte produced, which is a matter capable of regulation. On the same grade of matte the comparative losses should be about equal, but where an effort is made to reduce the coke on the blast furnace and run with high blast, the oxidizing effect in the furnace will produce greater slag-loss than on roasted material smelted in a reverberatory. Dust-loss will be much higher on blast-furnace work, especially if running on fine.

9. Where the slag made is over 40% SiO_2, the reverberatory will give better results, unless the amount of copper and matte is large, which is not usually the case.

10. If the grade of matte is over 50%, and 12 to 15% fuel is used on the blast furnace, the slag will be lower than reverberatory slag on the same grade of matte, due to the reducing action of the coke. If the blast furnace is run on, say 5% of coke with high blast, then I think the reverberatory slag will be lower than that from the blast furnace.

11. Owing to the rapid driving of copper blast furnaces, and the necessity for economy in labor, as well as the general efficiency of mechanical feeding, some form of dumping charges into the furnace is necessary and advisable.

12. I have used only one kind of briquetting plant for fine, and I found it very wasteful and expensive to operate. Successful bricking of fine can only be done under two sets of conditions, either hot and dry weather or cold and dry. At El Paso, fine was first bricked by me in 1888 by bonding with common red clay and sun drying, 10% of clay being used. At Argentine and El Paso, I put in a common pug-mill such as is used in brick-yards, and I made the bricks by hand. At Argentine, they were dried on top of the reverberatory roasters, being taken off with a long-handled shovel by a man on the furnace-wall and handed down to another man, who stacked them in charge barrows. At East Helena, a Chisholm, Boyd & White machine was used, the fine being bonded with milk of lime, which is no use in wet weather unless it is dried on the roasters, as above described. In cold weather the fine stuff becomes simply frozen, and for all purposes I would prefer frozen briquettes to those bonded with lime, because they stand handling better; and after they are in the furnace, they do not make any more dust than the other kind. As lime was always used, I am not able to say what the result would be if it were not used. I think, however, that some bond is necessary to make the briquette hold together until frozen. All the briquetting I have done has been done on material treated for lead, and I have never found it necessary to briquette flue-dust for copper smelting. Simply wetting it and smelting with coarse green ore, gives good results and avoids the expense for plant, and the trouble and expense of operating it.

The difficulty of treating fine in a blast furnace is that you do not treat it, finding most of it in the flue ready for another treatment. It is like the Irishman's flea, being always somewhere else. This is especially true where high blast is used. If, however, the flue-dust is allowed to accumulate during the month until the 25th or later, and then a charge is put on consisting of equal parts of green ore, wet flue-dust and converter slag, with about 11% coke and about 20 oz. blast pressure, it will smelt to a fair grade of matte in our case and not produce more than 20% as much dust as was fed in. Generally speaking, it is not necessary to re-charge flue-dust more than two or three times until it disappears. Possibly, it is smelted. The production of flue-dust is about 1% of the total charge, including coke.

The Separation of Gold in Antimony Ores.

Written for the MINING AND SCIENTIFIC PRESS by F. H. MASON.

Some time ago it fell to my lot to attempt to find a process for the separation of the antimony from the gold in an auriferous antimony ore. An idea of the nature of the ore may be obtained from the analysis of a concentrate made from samples broken in different parts of the mine.

Insoluble matter (principally silica with a little slate)	19.90
Antimony as sulphide and oxy-sulphide	30.00
Antimony as native metal	8.99
Lead	3.75
Zinc	0.53
Arsenic	0.21
Iron	7.35
Alumina	2.15
Manganese oxide	1.65
Lime	3.11
Magnesia	0.43
Sulphur	16.33
Carbonic acid	2.86
	97.26

It will be noticed that there is not sufficient sulphur to satisfy the antimony existing as stibnite, lead, zinc, arsenic and iron, so that the balance of the percentage, to make up the hundred, may probably be accounted for by oxygen, a little organic matter (which almost invariably accompanies a concentrate) and, possibly, a little fixed alkali, which was not determined. The concentrate contained 1.566 oz. gold per ton of 2,000 lb. This concentrate was made by Mr. E. P. Brown, of Bridgewater, Nova Scotia. Mr. Brown, in his report upon the concentration test, states that while 90% of the antimony was contained in the concentrate, only 38.4% of the gold was retained; so that it would be necessary for the tailing, which contained $4 in gold and one per cent antimony, to undergo some form of treatment for the recovery of the gold. Mr. Brown expresses the opinion that probably there would be no difficulty in treating the tailing by bromo-cyanide.

The first experiments with the concentrate, consisted of various modifications of cyanidation with the view, if possible, to removing the gold and leaving the antimony for subsequent treatment. Straight cyanide with solutions varying from 0.1 to 1% were tried over periods of from one to five days, the cyanide being brought up to strength from time to time. The ore decomposed the solution rapidly, and practically no extraction was obtained. Mixtures of potassium cyanide and bromo-cyanide were next tried; the bromo-cyanide prevented the decomposition of the solution, but failed to attack the gold to an appreciable degree. The best results obtained were less than a 10% extraction in 24 hours; and to obtain this the concentrate had to be ground to pass a 100-mesh screen.

Some experiments with cyanogen chloride were tried, which were exceedingly interesting, not from a commercial point of view, but because the liquid, after filtering, gave a remarkable cobalt-blue color, which turned to a claret on acidifying. The color remained permanent for days at an ordinary temperature, but on attempting to crystallize the salt by evaporation, the color (whether the alkaline blue or the acid claret) disappeared with precipitation of sulphur. Apparatus for crystallizing in a vacuum was not at hand, so the matter was dropped for the time. The reason for the failure of the bromo-cyanide and chloro-cyanide to attack the gold, was attributed to the presence of metallic antimony, causing re-precipitation. The solution, after 24 hours' contact, did not show serious decomposition and would attack gold leaf actively. Addition of other oxidizing agents, such as hydrogen peroxide and sodium peroxide, to the cyanide solution, failed to make the latter effective in attacking the gold. It is a little doubtful even if a fair percentage of the gold could have been removed by cyanide whether it would have left the antimony in a merchantable form. It was absolutely necessary, in order to get any attack at all by the cyanide, that the ore should be in a very fine state of division; buyers, as a rule, do not want all the ore in the form of fine.

About this time some people arrived in Halifax, from Ontario, who were prepared to make a demonstration of a process they had devised by which they could save all the antimony, gold and sulphur in the ore; and, further, they could recover all the reagents used in the operation. This was a nice, modest claim and so anxious were the owners of the ore to see it in operation that the inventors persuaded them to put up the necessary funds for the demonstration.

A shop was rented and the necessary plant installed; the latter consisted of a row of small wooden vats and a second row of similar vats above them; all the vats were sealed and connected with lead pipes. In these vats the ore was placed, together with hydrochloric acid, and they were heated by steam from a small boiler. The escaping vapors passed through a leaden worm, placed in running water, where they were condensed. It was my duty to investigate the process on behalf of the owners of the ore. Three gentlemen arrived with the outfit; two of them appeared to have duties of a purely financial nature, while the third was introduced to me as the chemical wizard. The wizard shot off a good deal of popular chemistry to a motley crowd who listened eagerly and took in nothing; he was a good talker, and he carried the crowd with him. On an old counter, he had arranged a number of test glasses, in which antimony had been precipitated from its chloride as sulphide, by hydrogen sulphide; as oxy-sulphide, by sodium thiosulphate; as oxy-chloride, by water; as ferrocyanide, by potassium ferrocyanide; and as metal, by old nails. These formed a few of the pigments the wizard could make from the ore.

Wishing to draw the wizard out and at the same time not to appear too critical, I asked a few inane questions; he at once pounced upon his prey and a conversation ensued somewhat after the following:

Q. Do you know anything about chemistry?

A. A little.

Q. Very good. Now that ore is being dissolved in hydrochloric acid, and I can precipitate the antimony as any of these pigments, all of which are very valuable. The gold is left in the residue; having removed the antimony I can get the gold into solution with nitro-hydrochloric acid. Do you understand chemical equations?

A. If they are not too complicated.

Q. Very good. Now take that orange precipitate you see there; how do I get it? Why, I take the sulphureted hydrogen I get, while the ore is being dissolved and with it I precipitate the antimony chloride formed, and thus I get back the whole of the hydrochloric acid, see?

$$Sb_2S_3 + 6HCl = Sb_2Cl_6 + 3H_2S$$

Very good; now

$$Sb_2Cl_6 + 3H_2S = Sb_2S_3 + 6HCl.$$

I am bound to say I was struck with the way the wizard used these equations for his own purpose; both the equations given, as far as they go, are accurate, but unfortunately a chemical equation does not take temperature into consideration, nor does it consider water unless it absolutely undergoes decomposition during the reaction.

The first of the wizard's equations expresses a reaction which takes place with cold concentrated hydrochloric acid or hot medium dilute acid. The second equation expresses a reaction taking place with moderately concentrated cold acid or hot dilute acid with an excess of hydrogen sulphide. Thus the acid obtained from the second equation is powerless without concentration to bring about dissolution of fresh ore.

Unfortunately for the wizard, the ore provided for him to treat had nearly 20% native antimony, and upon this hydrochloric acid had no appreciable action, so that he had to retire from the field of his own accord; otherwise, I verily believe he might have persuaded the owners to erect a plant, notwithstanding my efforts to the contrary; so excellent a talker was my friend the wizard.

But to return to my own experiments. At this time the owners were shipping selected ore to England; by the time transportation, brokerage and treatment charges were paid, this ore only realized about one-fourth its assay-value. Added to this, consideration has to be taken of the fact that it probably required the removal of from six to ten tons of ore to obtain one ton of selected material. The ore shipped ran from 40% to 45% antimony and about $50 in gold. My next experiments were on some of this selected material. It occurred to me that possibly by raining a small amount of metallic antimony through molten sulphide, the gold might leave the sulphide and follow the metallic antimony, and if so, the same metal could be used over and over again on different charges of sulphide until it attained a richness, the degree of which would have to be found by experiment, when it would have to be treated for the gold. To test this theory a quantity of the ore was liquated. The following is the result of the liquation:

Liquated regulus	76.6 per cent
Residue	16.8 " "
Loss by volatilization and adhering to crucible	6.6 " "

The regulus contained 2.66 oz. gold and the residue 0.7 oz. gold per ton.

The residue which contained about 12% antimony was smelted and the metal obtained contained practically all the gold in the residue; this metal was crushed and showered on the top of molten regulus contained in a crucible; the crucible was allowed to remain for a time in the fire to give the metal a chance of settling, and the contents poured. No metal was found at the bottom of the ingot of sulphide, but the regulus had increased in weight by more than the weight of the added metal. It is assumed that the powdered metal oxidized and formed with the sulphide a regulus of oxy-sulphide. This regulus was returned to the crucible and fine iron turnings were added and stirred in; two lots of iron were thus added. Each addition was arranged to reduce 10% of the metal; on pouring, 25% of the metal was found to have been reduced, which on assay proved to contain 84.3% of the gold in the regulus. A number of other experiments were tried on these lines, but nothing practical promised. Another set of experiments was made by fusing the regulus with soda ash and pot-ashes and adding varying quantities of metallic iron to precipitate a part of the metal. It was found that it was necessary to precipitate from 20 to 25% of the metal in order to get over 90% of the total gold concentrated in it. It was evident that it was necessary to precipitate too large an amount of antimony for this process to be of any practical utility.

Leaching the ore with sodium sulphide with a view to removing the antimony, was tried next. For these experiments, the concentrate previously mentioned was used; it was treated with a hot 15% solution of sodium sulphide for six hours, and 82% of the antimony went into solution; but when the residue was assayed, it was found that 17.8% of the gold had gone into solution also. As only 77% of the antimony existed as sulphide, it will be noticed that the sodium sulphide had attacked the native metal; this was expected, and it was for this reason that the sulphide was used in preference to the hydroxide; the sodium sulphide first coats the particles of metallic antimony with sulphide, which is dissolved in excess of the reagent. Of course sodium sulphide was known to be a feeble solvent for gold, but such a marked attack upon that metal was not expected. Solutions of sodium sulphide, both hot and cold, and of varying strengths, were tried, but to get any attack upon the native antimony, invariably meant an attack upon the gold also, and for this reason the use of sodium sulphide had to be abandoned. Wet reactions on the raw concentrate, for the removal of either the gold or the antimony, having proved futile, it was now decided to subject the ore to a preliminary roast. When antimony ore is roasted, two oxides are formed, namely, antimony trioxide, which is volatile and passes out of the furnace, and antimony tetroxide, which is fixed and remains in the furnace with the gangue. The tetroxide is not appreciably attacked by solutions of acids, alkalies, cyanides, chlorine or bromine, so that if no gold were lost in roasting the ore, there appeared to be no reason why the precious metal itself should not be recovered from the residue, by either chloride or cyanide. The proportion of trioxide formed by roasting varies with the temperature at which the operation is carried out; a low temperature appears to favor the formation of tetroxide. Of course the temperature must be kept very low during the early stages of the roast, on account of the low melting point of stibnite.

The concentrate was found to lose from 14 to 30% of its weight by roasting; the variation depending entirely upon the temperature and being due to varying amounts of the trioxide formed. A number of roasts were made and in no case was as much as three per cent of the gold lost during the operation. Chlorination of the roasted ore was attempted first. The chloride of lime used (the best that could be obtained locally) was of poor quality and only yielded 20.5% available chlorine, while material of good quality should yield 35% available chlorine.

A large number of experiments were made, and it was found that 75% of the gold could be extracted from the roasted ore by agitating it for 24 hours with three per cent (of the weight of the ore) chloride of lime and six per cent sulphuric acid. The best results were obtained when all the acid and one per cent of the lime chloride were added at the beginning of the operation, a second portion of the lime chloride after eight hours and a third portion ofter 16 hours' agitation. The large amount of acid was necessary in order to neutralize the lime in the ore itself. An addition of two per cent of salt was made at the termination of one of the roastings with a view to cutting down the acid

necessary and, if possible, of improving the extraction. On assaying the roasted ore, it was found to have lost 49% of the gold, by volatilization. Cyanidation of the roasted ore was less successful than chlorination; the best result obtained was an extraction of 27% of the gold by agitating for 60 hours with 0.2% potassium cyanide and 0.05% cyanogen bromide.

It was now decided to reduce the antimony tetroxide to trioxide, and remove as much of the antimony as possible out of the furnace. The concentrate was mixed with 20% its weight of powdered anthracite and roasted, when most of the sulphur was burnt off. The temperature was raised sufficiently to ignite the anthracite. The quantity of air entering the furnace was now reduced and the charge, which had to be rabbled energetically in the early stages of the roast, was now only turned over every few minutes, when fumes of the trioxide had almost ceased to come away; more anthracite was added and mixed with the charge by energetic rabbling. Anthracite was added from time to time in this way, until its further addition failed to produce fumes of trioxide of antimony; which was the signal that the roast was completed.

In the small-scale experiments made (200 to 500 grams) it was found that this concentrate required about 40% its weight of anthracite in order to remove nearly the whole of the antimony; powdered coke answered equally as well as anthracite. Experiments showed that the residue could be relied upon to contain 97% of the gold, and in several of them it contained over 99%. By carefully regulating the draft, the antimony contents of the residue have been reduced to as low as 0.6%, but it more often ran from 1 to 1.5 per cent.

The theory of the process is, of course, evident. The tetroxide is reduced first to trioxide and then probably to metal, while the incoming air oxidizes the metal first to trioxide and then to tetroxide; in this way, the antimony is oxidized and then reduced, and at each oxidation and reduction it passes through the stage of trioxide when it is volatile and has a chance to escape out of the furnace. The antimony trioxide is collected in condensing chambers and is in a condition well suited for direct reduction to metal by fusion with carbon. The condensing chambers will also contain the arsenic and zinc as oxide and a little of the lead also as oxide, but as the two former exist in such a small proportion in the original concentrate, they will probably not seriously affect the antimony produced. With regard to the residue, it contains from 5 to 6% lead, together with 1 to 1½% antimony and is clearly suitable for smelting, as it contains in itself nearly sufficient base metal in which to concentrate the gold. A sample of the residue was submitted to the American Smelting & Refining Company for a quotation, and they offered to pay for the whole of the gold at $20 per oz., 4.5c per lb. for the lead, less 1.5c importation duty and to charge $6 per ton for treatment.

Here then appears, as far as it is possible to tell by laboratory experiments, a process by which the gold and antimony may be successfully and commercially separated from each other. If the ore were closely concentrated, so that the concentrate contained only from 10 to 15% gangue, the amount of material to be smelted—compared with the original ore—would be quite small. Experiments were tried with both chlorination and cyanide upon the residue, but in neither case was an extraction obtained which would commercially compete with smelting.

Mr. J. S. McArthur—of cyanide fame—has given this ore some attention; unfortunately, his experiments were conducted upon a sample which contained little or no native metal. He has devised an exceedingly pretty process which, however, is not suited to ore containing much native metal. He removes the antimony by leaching it with a two per cent solution of caustic soda; this solution is treated with carbonic acid, which re-precipitates the antimony as sulphide, and the solution—after the removal of the sulphide—is regenerated by the addition of caustic lime. The reaction may be expressed by the following equations:

$$Sb_2S_3 + 6NaOH = Na_3SbS_3 + Na_3SbO_3 + 3H_2O$$

$$Na_3SbO_3 + Na_3SbS_3 + 3CO_2 = Sb_2S_3 + 3Na_2CO_3$$

$$Na_2CO_3 + Ca(OH)_2 = 2NaOH + CaCO_3$$

The residue, after the removal of the antimony, Mr. McArthur first roasts and then cyanides.

In conclusion, it may be of interest to give the method used for determining the antimony. The quantity of material taken for the assay is such that it contains in the neighborhood of 0.2 grams antimony; to this is added 15 c.c. hydrochloric acid and a like amount of water, and it is digested at a temperature of 80° until sulphureted hydrogen ceases to be evolved. Nitric acid is now added, a drop at a time (the beaker containing the assay being replaced for a few minutes on the hot plate after each addition), until the native metal is dissolved. The solution is then filtered from the residue and the latter is washed with a 10% solution of hydrochloric acid. The antimony is precipitated from the filtrate by adding three grams of spongy tin and the solution is kept at about 80° C.; the precipitation of the metal takes from one to one and one-half hours. The antimony is allowed to settle and the liquid decanted through a filter, and the metal washed by decantation, with a 10% solution of hydrochloric acid; the washings, of course, going through the filter.

The metal is washed into a flask, 15 c.c. of strong hydrochloric acid and a few crystals of potassium chlorate are added, and the solution is made up to about 50 c.c. The flask is placed on the hot plate and when the antimony is dissolved, it is boiled briskly until free from chlorine; it is then cooled, three grams potassium iodide added, the solution made up to 200 c.c. with water and the liberated iodine titrated with standard thiosulphate from which the antimony is calculated.

In order to get the antimony in the roasted ore into solution it is first gently fused with potassium cyanide which converts the tetroxide and any insoluble antimonates into the metal. The mass is leached with water and the residue treated as a soluble ore.

Muntz Metal Plates

Written for the MINING AND SCIENTIFIC PRESS by A. R. PARSONS.

The Bamberger-DeLamar Gold Mines Company is grinding ore in a 0.15% cyanide solution, the pulp being allowed to flow direct from the Chilean mills to amalgamating plates. Formerly copper plates 1-8 in. thick with one ounce of silver per square foot were used. These rapidly became rough and pitted, and at the end of two months were found to be ragged at the lower end and practically destroyed unfitting them for amalgamating purposes and necessitating their removal.

As a trial two muntz metal plates 1-8 inch thick, with one ounce of silver per square foot were installed and they proved such a success that the copper plates were replaced by muntz metal throughout. The life of the latter is more than four times that of the former. The muntz metal amalgamates readily, the amalgam being easily detached, facilitating a rapid clean up. The amalgam is not absorbed by muntz metal to such an extent as by copper. This was recently proved on bars formed by melting two old copper and two muntz metal plates, the latter having been in use much longer than the former. New plates from the alloy do not require the careful attention and manipulation that is necessary with new copper plates. The discoloration and appearance of "verdigris" experienced with copper is no longer noticed.

Care must be observed in using mercury for dressing, as the muntz metal will not hold the mercury like copper, and if a slight excess is used it will collect in globules, and for this reason it is advisable to brush the plates more frequently than is customary with copper. We unhesitatingly recommend their use where amalgamation is carried on in a cyanide solution.

On what grade must a flume be built for it to discharge a given quantity of water in a given time? Divide the number of cubic feet of discharge wanted by the area of the section of the flume in square feet. This will give the necessary velocity. Multiply this result by itself and multiply the product by the wet perimeter, in feet, of the flume and multiply the product by 0.0001114. Divide the product by the area of the section of the flume, expressed in square feet. Call this A. Multiply the velocity in feet per second by the wet perimeter, in feet, and multiply the product by 0.00002426. Divide the product by the area of the section of the flume, in square feet. Call this B. Add A and B. The result will be the grade expressed in decimals of a foot

---

The extraction of gold from its ore by free milling process consists of two operations: the pulverization of the ore to free the gold from its matrix, and amalgamation of the particles of gold with quicksilver. These two processes, simple in themselves, have many modifications in the practice of various districts, the variations being necessitated by the difference in the character of the ores. Concentration is wholly independent of amalgamation. Some gold ores require no concentration; others can be worked in no other way than smelting.

A New Method of Smelting Butte Ores.

Written for the MINING AND SCIENTIFIC PRESS by WILLIAM A. HEYWOOD.

Since August, 1905, the smelter of the Pittsburgh and Montana Copper Co., situated on the flat about two miles east of Butte, Montana, has been running continuously and producing about 100 tons of copper per month by the Baggaley process. While the entire plant invented by Mr. Ralph Baggaley has not yet been installed, enough has been done, that is different from the usual methods of treatment, to demonstrate the success of his ideas in eliminating water-concentration and roasting, substituting the use of a basic-lined converter producing copper from matte of low copper tenor and employing silicious ore for flux in the converter.

The smelter is situated close to the No. 2 shaft, from which all the copper ore now being mined by the company is raised. The ore has the following average composition:

Copper, 2 to 4 per cent; silica, 52 per cent; iron, 14 per cent; sulphur, 17 per cent; alumina, 7 per cent; magnesia, 1 per cent, and zinc, 2 per cent.

The company also owns the Spring Hill mine near Helena, from which it gets about 50 tons per day of pyrrhotite ore, having the following composition:

	First Class	Second Class
Silica,	9 per cent	30 per cent
Iron,	48 per cent	31 per cent
Sulphur,	32 per cent	13 per cent
Lime,	5 per cent	23 per cent
Copper,	None	None
Gold,	$7 per ton	$2 per ton

Some experiments in smelting this ore pyritically, using Butte ore for flux, have been made, but as the quantity of silicious copper ore is far in excess of the pyrrhotite, a partial pyritic charge has been found more satisfactory. The fuel value of the sulphur in the pyrrhotite is used as well as the iron for flux. The extra base required for flux is added in the form of limestone.

The blast furnace used was designed to experiment with the Garretson process. These experiments proved a failure and the furnace has been used as an ordinary blast furnace. It is built of cast-copper water-jackets, 38 by 158 in. at the tuyeres. It has 14 three-inch tuyeres on each side. The distance from the tuyeres to the charge floor is nine feet.

The materials smelted since September 1, 1905, are as follows:

	In blast	Lime-rock	Butte ores	Pyrrho-tite	Converter and blast furnace Matte	Converter and blast furnace slags	Total	Coke
	Days	Tons	Tons	Tons	Tons	Tons	Tons	Tons
Sept.	22	775	2097	1495	180	170	4717	528
Oct.	31	933	3053	1307	825	624	7078	637
Nov.	25	814	2786	1235	584	302	5723	474
Dec.	31	1143	3551	1631	112	262	6699	606
Jan.	31	1316	3589	1389	200	166	6660	664
Feb.	28	1263	3308	1062	267	225	6125	612

The average of the slag and matte is as follows:

	Cu. in. matte	Cu.	SLAG ANALYSIS SiO_2	FeO	CaO
	Per cent	Per cent	Per cent	Per cent	Per cent
Sept.	8.6	0.11	46.1	21.1	20.4
Nov.	20.6	0.24	42.2	29.7	17.2
Dec.	24.2	0.24	43.6	25.5	18.7
Jan.	28.2	0.21	43.8	21.9	21.4
Feb.	23.8	0.19	44.0	22.0	20.0

These slags also contain 7.5% Al_2O_3; 2.5% MgO; 2.5% ZnO and 0.5% sulphur.

No effort was made to obtain a high rate of concentration in the blast furnace. Employing iron sulphide (pyrrhotite) as a flux, reduced the grade of the resulting matte, but lowered materially the amount of coke necessary to smelt the mixtures and the copper lost in slag. It will be noted that these slags are the cleanest ever produced from Butte ores. As our matte was treated in a basic-lined converter using silicious ore as a flux, this low-grade matte produced in the blast furnace was not a source of expense in converting, as it would be if an ordinary silica-lined converter were used. It might be argued that this occasioned greater loss in converter-slags on account of the greater volume of slag made in the converter from these low-grade mattes. These converter-slags, from November onward, were poured in molten state into the blast furnace, consequently the assay of the blast-furnace slag includes the copper loss of the converters. It will be noted that 624 tons of converter-slag were smelted during October. During this month the slag from the converters was cooled, broken up and added to the blast-furnace charge.

During November, December and January the tonnage of converter-slag is much less, as no account is taken of the molten converter-slag poured through the blast furnace. The slag weighed during those months represents the 'hulls' left in the ladles and the necessary cleaning up about the converters and blast furnace. The amount of slag made per ton of ore smelted varied with the different charges from 1900 to 2300 lb., and the slag-loss is from 5.4 to 6 lb. copper per ton of ore smelted.

Our extraction of copper in the blast furnace has been about 90%. Taking the Butte ore at 4% copper, this would produce 320 lbs. of 25% matte per ton of ore. The iron in this matte when fluxed with Butte ore would form about 300 lb converter slag. As this slag was discharged at 0.24%, the loss of copper in converter-slag equals 0.72 lb. copper per ton of ore smelted in the blast furnace, or a total smelting loss in both blast furnace and converter of less than 7 lb. copper per ton of ore smelted. I have not taken into account flue-dust losses, as with proper chambers and flues the losses in this way are small and are no greater by our method than by the older plan of treatment. At this point it may be interesting to compare our loss of 7 lb. copper per ton of ore smelted with some of the results of other smelters. At Granby, with self-fluxing ore and a charge of nothing but ore and coke in the blast furnace, I am informed that the blast-furnace slag loss is 7 lb copper per ton of ore smelted. At the plant of the Tennessee Copper Company, with a low-grade pyrrhotite copper ore using barren quartz for flux and a double pyritic smelting, the loss of copper is about 9.4 lb. per ton of ore smelted. What the copper loss in the treatment of Butte ores by other companies may be, is difficult to say. Neither the Amalgamated nor the Montana Ore Purchasing Company (United Copper Co.) publish any data regarding their extraction. We do know, however, that a 4% copper ore such as we have been smelting would be consigned to the concentrator and the best saving claimed for water concentration in the Butte district is 80% of the copper. On this basis 16 lb of copper would be thrown away in tailing. In other words, they lose more than twice as much copper before they start smelting as we do during our entire process.

1. We smelt directly our low-grade ores. Others classify their ores and send the high grade to the blast furnace and the low grade to the concentrator. The standard of what constitutes first class ore is gradually being lowered and is now about 5% copper or over. This lowering of the standard indicates the trend of metallurgists to avoid the wasteful practice of water concentration.

2. We employ pyrrhotite or iron sulphide ores for flux. If this has an assay-value it is a much cheaper flux than barren limestone, because it materially reduces the quantity of coke required to smelt the charge.

3. We make a low-grade matte in the blast furnace and thereby make the cleanest slag and the lowest copper loss ever obtained from Butte ores. The employment of a basic-lined converter and the smelting of silicious ore in the converter as flux for the iron in these low-grade mattes enable us profitably to convert low-grade matte where the cost of continually re-lining a silica-lined converter would be prohibitive. Since the other Montana companies started lining their converter shells with ore and adding silicious ore to the converter-charge there has been a gradual reduction in the grade of matte that it is profitable to convert, and there has followed a diminution in their blast-furnace slag-losses.

4. All our converter-slag, except the small proportion that chills in the ladles, is poured molten into the blast furnace. This cleans the slag by allowing the particles of matte to settle; there is a beneficial effect on the blast furnace by scouring it out, and saving the cost of handling and re-smelting.

CONVERTING.—Prior to October 7, the converter plant was not used except in experiments. The old vertical blowing-engine having broken down, a new horizontal cross-compound Reynolds engine was purchased and installed. The blast-furnace matte made up to October 7, was either sold to the Montana Ore Purchasing Company or stored.

The converter employed in the Baggaley process is composed of steel rings 11 in. thick and 18 in. wide. It is lined with one course, 9 in., of magnesite brick. The cap is not lined. The total length of the converter is 13 ft. The length inside the brick lining is 9 ft. 6 in. The outside diameter of the converter is 8 ft; the diameter inside the lining is 4 ft 9 inches.

The method of operating is as follows. About 1000 lb. ore is placed in the converter and a tap of four or five tons of low-grade matte poured in. The charge is then blown with the addition of ore in 1000-lb lots until the matte is 'high', that is, the iron has been eliminated.

The slag is then poured off and a fresh tap of matte added with more ore. When it is desired to finish a charge, the white metal in the converter is blown to copper in the usual manner, without the addition of ore.

The converter works freely and quickly, and its large size permits large quantities of matte to be handled. With matte containing 10% copper I have added 60 tons before finishing it and kept the charge blowing for 48 hours before pouring copper. With matte containing 30% copper we have finished a charge in three hours. The size of the copper charges as poured depends, of course, on the grade of the matte and the number of taps added; we have finished charges of less than a ton of copper and also charges of seven tons of copper. As the lining remains the same size, there is much greater freedom and elasticity in the sizes of charges than with a silica-lined converter.

From October 7, 1905, to January 31, 1906, we have made over 500 tons of copper. The same magnesia lining that was in the converter at the start is still in use. The only repairs have been the renewal of some of the bricks about the tuyeres, on four occasions, when they had become dislodged or broken by the punching of blocked tuyeres. Our blast furnace being small and our ores low grade, we have been unable to keep the converter supplied with matte. If we had all the matte the converter could handle it would turn out over 500 tons of copper per month. As our matte is much lower grade than that which anyone else attempts to convert, to the best of my knowledge, this is better work than was ever done by a silica-lined converter.

With this kind of converter not more than five tons of copper, from low-grade matte, could be made before the converter would require re-lining, that is, the converter would be lined 100 times for our 500 tons of copper. The labor and power used in re-lining is at least $10 per shell, so the saving in labor of re-lining alone is $1000 up to January 31. We have smelted 1118 tons of silicious ore in the converter at practically no cost. The labor required on each shift is one skimmer, one puncher and one helper. The converter has given less trouble than any converter I ever ran, although I had never before attempted this method of converting and the entire force of men were inexperienced in converting in a basic-lined converter.

The following table shows the amount of Butte silicious ore (50% SiO_2; 14% Fe) required to form a converter-slag of 30% SiO_2, 60%FeO with 5 tons of copper mattes of various grades:

Copper in Matte.	Ore Required.
5 per cent.	9350 lb.
10 per cent.	8700 lb.
15 per cent.	8050 lb.
20 per cent.	7450 lb.
25 per cent.	6800 lb.
30 per cent.	6200 lb.

The desirability of using a basic-lined converter and introducing the necessary silica by some other means than the destruction of the lining has been recognized since the introduction of the Bessemer process in treating copper mattes. Until it was successfully accomplished at the Pittsmont smelter, it has never been done.

Mr. Herman Keller, while superintendent of the Parrot smelter, at Butte, about 1890, attempted converting in a shell lined with magnesite. A record of his attempts and failures, written by him, is given on pages 570, 571 and 572 of 'Modern Copper Smelting,' by Peters. The three reasons given by Mr. Keller why the basic-lined converter was a failure and the process abandoned at the Parrot, have never been in evidence at the Pittsmont, in the special converter patented by Mr. Baggaley. Taking the three reasons separately I would reply as follows:

1. The outside of the converter has never been "dangerously hot." Considering the grade of the mattes treated, the converter works much quicker than any silica-lined converter I have ever used.

2. We have never experienced any difficulty in adding silicious ore to the converter in such a manner that it would combine with the ferrous oxide.

3. As the same lining has lasted five months and is still in service, there cannot be any "shelling" of the magnesite brick worth mention. Moreover, if the magnesite lining were now completely destroyed, it has paid for itself in the saving of labor alone required in re-lining a silica-lined converter.

The following are the points of difference between our blast-furnace practice and that of other companies treating Butte ore.

At least 10,000 tons of copper ore are now mined daily in Butte. Probably one-fourth, or 2500 tons, is considered first-class and smelted directly in the blast furnace. The remainder, 7500 tons, is consigned to the mills for water concentration. This ore averages over 30% copper, consequently the loss of 20% in tailing entails a daily loss of over $15,000 before smelting commences. This loss represents at least $2 per ton of second-class ore treated or nearly double the smelting cost at Tennessee or Granby. In order to obtain water, to wash 20% of the values away, most of the ore has to be hauled by railway to Anaconda and Great Falls. The concentrate containing the 80% of the value saved is too fine for pyritic smelting in the blast furnace and contains too much sulphur for reverberatory smelting, consequently it is roasted. This roasting is a waste of the fuel (sulphur) contained in the ore, in addition to the expense of the operation. The roasted concentrate is too fine for the blast furnace, so it is treated in reverberatory furnaces. Reverberatory smelting is not only more costly than blast-furnace smelting, but the losses in slag are much greater.

I am informed that in the blast furnaces of the Washoe smelter at Anaconda, they have tried a mixture of all their Butte ores in the proportion they were received for a year with very satisfactory results. They obtained a 50% matte, lime being used as a flux. If iron sulphides were employed to replace part of the lime, the loss in slag would have been lowered, as the blast-furnace matte would have been of lower grade, and the coke consumption materially lessened.

In the Mineral Industry for 1901, page 698, Dr. Franklin Carpenter states: "I have smelted many thousand tons of Butte copper ores at the Deadwood plant and have no hesitancy in stating that the whole of the concentrating and roasting machinery employed around the Montana smelting works is unnecessary, provided the process of pyritic smelting is employed that was first developed at Deadwood, S. D." Considering the strides in pyritic smelting since 1901 and in view of our experiments, how much more wasteful and unnecessary does the present method of water concentration and roasting appear!

To treat the Butte output pyritically a large amount of iron sulphide ore would necessarily be employed. When the large amount of first-class ore is considered, much less iron and lime would be needed than we have employed in treating only the lowest grade and most silicious of Butte ores. Whether it would be more profitable to bring iron ores to the copper ore or haul the copper ore over the mountains to obtain water to wash away 20% of their value, can easily be demonstrated. Without a large quantity of iron sulphide ores and using only limestone for flux, with what iron ores of any kind that can be obtained, the treatment of Butte ores in blast furnaces and converters has been demonstrated to be more economical than the methods now employed by all companies in Montana except the Pittsburgh & Montana Copper Company.

Adjustable yokes for the support of steam, air and other pipes in mine-shafts may be made by bolting together two pieces of 4 by 4-in. timber, if necessary, larger dimensions, and boring or cutting out on the center line a hole having a somewhat smaller diameter than that of the pipe. The bolts may be unscrewed, one side taken off and the yoke placed in position in the shaft, the ends resting on the timbers. The bolts should have square heads and each end should be provided with a washer of sufficient size to prevent the bolt-head or nut from sinking into the wood when tightened. A yoke of this kind may be changed from one set to another, if occasion requires. Pipe should be connected with flanges, at least every 40 to 60 ft. of its length. Ordinary sleeves may be utilized at the intermediate joints.

Every group of mine and mill buildings should be protected from danger of fire by hydrants situated at points commanding the various buildings. At some California mines giants such as are in use in hydraulic mines are placed at some central point where any of the buildings or timber piles in the yard may be reached with a large stream of water under high head in case of fire.

In the early stage of development of a quartz mine it is often impossible to tell whether or not the ground is more valuable for mineral or agricultural purposes. A vein small and low-grade upon the surface may develop into a very valuable mine in depth. Several such instances are of record in California.

Special Correspondence.

LONDON, April 11.

From an intermediate report issued by Stratton's Independence Ltd. it appears that the development work during the first half of the current financial year to December 31, 1905, amounted to 2035½ ft., comprising 928½ ft. in drifts, 527 ft. in raises, 13 ft. in winzes and 567 ft. of crosscuts. It is noteworthy that of the 48 points of development 44 show substantial average assay-values, these running from $12 to $36 per ton. The stoping amounted to a total of 31,026 tons of crude ore, which averaged $22.7 for an average width of 4.23 ft. It is stated that in the granite area, ore continues at and below the 200 ft. level. During the six months under review, July to December, 1905, inclusive, 16,027½ tons of shipping ore were produced from the mine and sold, of a gross value of £128,033. From the dump, 2,192 tons of shipping ore were concentrated and sold, of a gross value of £3,728. Total gross value of sales £131,761. Average value of the shipping ore, 1 oz. 17 2-5 dwt. gold per ton.

According to the report, the royalties and share of profits received from the lessees during this period amounted to £37,613. After adding sundry receipts and deducting the Company's establishment and other expenses, there was a net profit at the mine of £31,926. The net profit at the mine for January last from 2,930 tons of shipping ore was £6,093, and for February from 2,112 tons of shipping ore £4,065. Total for the eight months £42,084. It is thought that under the new and augmented number of leases which run to August next, an increase in the production of ore may be looked for during the four months—March to June inclusive—to complete the financial year. The Profit and Loss Account, inclusive of profits to February 23, 1906, is shown to be approximately as follows:

Balance brought forward from June 30, 1905		£63,409.7.9
Add: Profit at mine, eight months as above	42,084.0.0	
Less: London expenses for the period, say	1,800.0.0	
		40,284.0.0
		103,693.7.9
Deduct three dividends of 6d. per Share, paid August 22, 1905, November 22, 1905, and April 10, 1906, respectively		75,000.7.6
Approximate credit balance, subject to audit		£28,693.0.3

The dividends paid by the Company now reach a total of £979,173.10.5. Reference is made to the Cassel process and it appears that further expert examination of the Cassel filter having amply confirmed the favorable opinion previously held of its merits, the Metals Extraction Syndicate, Limited, (in which Stratton's Independence Company holds a 1-5th interest) have exercised their option, and a parent company is now being formed to take over the filter and process patents for the whole world, with the exception of the Cripple Creek district. The company in question is to be registered with a nominal capital of £200,000, of which £25,000 has been guaranteed for working capital. The report concludes by stating that the proposed company (for which the rights have been reserved as above mentioned) to work the filter and process in the Cripple Creek district, has not yet been formed. Before this is done, prolonged and very careful investigation must be made into the values and quantities of ore available, before the erection of a mill, which will take a large amount of capital, can be definitely decided on. The dump is being very thoroughly sampled, and the consulting engineer, Mr. Geo. A. Schroter, is making a careful examination of the low-grade ore resources of the mine.

From the same "shop"—3 Princes Street, E. C.—another intermediate report has just made its appearance. It deals, in the first place, with the gross returns and other results of six dredges of Oroville Dredging Limited for the three months November 1905 to January 1906. During this period 794,669 yards were washed for a total return of $135,251 or an average yield of 17 cents per cubic yard. The operating costs amounted to 4.05 cents and the renewal costs 3.37 cents per cubic yard. The report states that the slight increase in the operating costs is due partly to the fact that a great deal of running time was lost during November and December, on account of poor power service occasioned by the long droughts incidental to the early winter season. It is pointed out that during the temporary shut-down, advantage was taken for general overhauling, which also increased the cost per yard at the mine, but the following months will derive the benefit of the repairs thus executed. The net profit, three months from the six dredges, operating on two properties only, viz., Boston and Oroville and Boston and California, is shown as $70,249.68. The returns from the Exploration Company's property began to come into the account as from 1st January last, and for that month yielded a net profit of $5,426.28. For the month of February the net profit from the three properties with the two additional Exploration dredges amounted to $45,000, a large increase on the previous monthly average from the two properties. After adding the profit from the machine shop and sundry receipts, and deducting the Boston office expenses, a net profit is shown for the four months of $121,375.96.

Referring to the Boston and Oroville property, the general manager, Mr. W. P. Hammon, reports: "Reviewing the operations of this company's dredges for the past six months, none of them seem to have been in average ground much of the time, and from the present positions of the machines, I would expect a marked improvement very soon. No. 1 has a long stretch of good ground before it; Continental, no doubt, will improve, and with the completion of No. 4, we will add materially to the output of this Company very soon." And on the subject of the Exploration Company's property, he remarks that the two dredges now added are doing well.

In their report the London committee state that with regard to the four new modern dredges, "Boston and Oroville No. 4," is expected to be completed by the end of April, while "Exploration No. 3" should be ready by the end of July. The third new dredge should also be available about that time, and the fourth will be put on order as soon as the first is running successfully. On the financial position they remark that with the issue of the 130,000 shares for the Exploration property recently made, the entire capital of 700,000 shares of $5 each now carries dividend, which, at the rate of 10 per cent per annum, requires monthly profits of a little over $29,000. Although the last quarterly dividend—paid on the 29th ult.—was from accrued funds to end February, which included only two months' profits on the working of the Exploration property, a surplus of profit is reported of $44,501.74, after payment of two quarterly dividends at the rate of 10 per cent. per annum. The London committee also draw the shareholders' attention to the fact that the two quarterly dividends at the rate of 10 per cent. per annum have been earned practically from the working of six dredges. With the addition of the two dredges now at work on the Exploration Company's property, and the four new dredges of the most modern type, all of which should be in operation before the end of the current year, the yardage capacity will be more than doubled, with less average operating cost. From these facts the committee conclude that no difficulty will be experienced in bringing up the net earnings to the rate originally contemplated, of upwards of 20 per cent. per annum.

At the seventh ordinary general meeting of Mount Boppy Gold Mining Co. Ltd., held last week, the chairman, Mr. A. Hoffnung, gave the shareholders a somewhat glowing account of his visit to the mine. He described how, accompanied by the superintendent, Mr. Thomas Pascoe, and the underground manager, Mr. Richards, he spent some considerable time exploring the various levels from the surface down to 400 ft., which was the lowest depth the mine had attained. He said he seemed to be traversing interminable distances beside gigantic walls of gold-bearing rock, the lode varying in width in places up to 60 ft. or more, and the value from a few pennyweights up to ounces of gold per ton, and considering the moderate depth yet reached he was struck with the possibilities before them both laterally and on deeper sinking. His inspection of the surface and efficient mill and appropriate machinery, an extensive cyanide, slimes and filter pressing plant. The chairman said he must not omit to mention the reservoir, which presents all the appearance of a capacious lake. They were rather concerned of late owing to the long absence of rain, and the diminution of their water reserve in consequence of the great evaporation, which is at its highest during the intense heat of summer, but the superintendent had cabled the news of welcome rain which as given a full 12 months' supply in the reservoir. Referring to the Cobar division of New South Wales, in which the mine is situated, the chairman spoke of it as one of the most prolific in valuable minerals in the State—gold, silver and copper are abundantly and prominently in evidence. The Great Cobar mine is one of the famous copper mines of the world. The official report of the Warden of the district, which he had before him, specifies the values of the output during the past four years as follows: Gold, £844,195; copper, £1,037,412, and silver, £23,176, aggregating two millions sterling, the product of the last year (1905) being considerably in excess of any of its predecessors. The number of men engaged in the various mines is 2,009, and the value of the machinery employed is £282,794. The district affords so much encouragement that the Warden refers to the presence of 400 prospectors on various parts of the Cobar field, where a discovery was recently made of an important outcrop, which gave such encouraging evidence of the probable existence of extensive deposits of gold, silver and lead, that the shares of the syndicate which was formed to explore it advanced to a phenomenal figure.

Dealing with the results in 1905, the year under review, the chairman said the mine had given gold to the value of £116,433.19.11, which affording a dividend of 47½ per cent. Thus the production of gold during the 48 months that the mill had been at work had each year steadily increased, and totalled the respectable sum of £330,610.2.9, or about three times the amount of their original capital, whilst the dividends had amounted to 133¾ per cent., aggregating £150,357. He reminded the shareholders that out of an area of 293 acres they had up to now actively carried on stoping operations within a space of only about 13 acres to a depth of but 400 ft., from which they had not only obtained the above-named results, but had disclosed the very ample reserves estimated at 182,000 tons, which should be worth more than £400,000, and on the same basis of calculation, that is, taking the net results of the past year, should contain a profit of about £230,000, or nearly double the amount of their capital.

The following cablegram just received refers to the report of the Geduld (Transvaal) commission of inquiry (consisting of Messrs. Weber, Wentzel, Leonard, and Sidney Jennings) appointed by the board to investigate the discrepancies discovered in connection with the assays taken from the No. 2 shaft: "Report of commission received. States commissioners have obtained evidence from all persons connected with taking and handling samples, as well as from assayers; also had tests made by metallurgical expert. Commissioners state delay caused through necessity taking evidence Europe of engineer, who meanwhile left Rand. Commissioners state in their opinion all reasonable precautions taken with regard to taking samples on mine, and difficult conceive any tampering or irregularity occurred there. Commissioners' finding is five samples, three from footwall leader and two from cross sections, represent either rock from some other locality than Shaft No. 2 or that free milling ore has been added to original samples. Commissioners have beeen unable to ascertain in what manner or by whom tampering samples effected. Investigations failed elicit any information justifying cast suspicion on any particular individual. Commissioners express appreciation of assistance rendered by board in acquiring evidence."

For the month of March a record gold output from the Rand is announced of 443,723 oz., exceeding the previous highest figure by 12,129 oz. A slight contraction in the industry is, however, noticeable; as compared with February there is a decrease in the average daily output of 246 oz. owing, it is said, to the diminished supply of unskilled labor.

Proof of the reviving interest in Cornish mining, consequent on the continued high price of the white metal, is to be found in the prospectus published "by way of information only" of The Cornish Consolidated Tin Mines Ltd. The capital is £100,000 in 99,000 ordinary and 1,000 deferred shares of £1 each. A good start has been given by the subscription of the seven signatories to the Articles of Association for 45,000 ordinary shares. The entire capital of the Company will be available as no brokerage commission or promotion money has been paid. The three directors are well known in mining and Stock Exchange circles. The purposes of the Company include the financing of mines already working and the supplying of information regarding Cornish mines. Some good points are made in this prospectus. It shows that during the past half century there has been no period when Cornish mining, given scientific methods and ample working capital, was not a paying proposition, and that with these aids it is highly payable at anything like the present price of tin. Taking the entire county, lode-values for tin may be assumed to average 2 per cent. of black tin or over £2 per ton, equal to 10 dwt. of gold, whilst working

costs should not reach one-half that amount. It is pointed out that, in addition to tin and copper,the county produces galena, zinc-blende, wolfram, iron and arsenical pyrites and a variety of rare minerals, which owing to their occurrence in complex form have hitherto proved rather a detriment than otherwise, but the marked success of Clitters United Mines Ltd. in dealing with such ores has practically opened up a new industry.

NOME, February 22.

Ten years ago the principal gold producing sections of the United States were California, Colorado, Arizona and Idaho; Alaska was then considered to be too cold, bleak and barren to become a mining country. And yet within the last ten years Alaska has produced over $40,000,000 in gold alone and by the arrival of the first boats in the spring there will be in the neighborhood of $5,000,000 more accumulated in the banks, awaiting shipment to the mints as the result of the winter's work since the close of navigation last October. Still the mining industry is only in its infancy, not half of the country now known is prospected and the greater part is still unexplored.

This is not a poor man's country. It is a country for capital, and nowhere is there better opportunity for the wise investment of it with a better chance of large returns than in Alaska today. There have been a few poor man's propositions where all the capital required were the tools and primitive equipment, with a month's provisions, to develop the claims to the point of paying a profit. Many more of these may yet be discovered, but they are so few when compared with the number that require capital to develop them, that a poor prospector's chance is slim. Alaska is not an easy country to explore by any means, for the prospector meets with many difficulties, which are at times discouraging. The successful Alaska prospector must be a man with determination and sufficient funds, say $1,000 or $1,500, to carry him through a couple of seasons. The novice without capital, trade or profession has no place here. For example, we will take the first discoveries on the now famous Little Creek, that has, up to the present writing, yielded over $2,000,000. About the middle of September, 1904, J. C. Brown offered his claim for sale at $6,000. It went begging, and had he found a purchaser at that price, it is not likely that the $6,000 would have paid him for what he had already spent. Determined to win, he kept on; a short time afterward he was rewarded by finding the rich streak from which he has been extracting pay-dirt ever since. Then followed the discovery on the Portland bench. The three tenderfeet who made the discovery sunk and drifted in every direction, and finally got discouraged, and were about to quit when they decided to put in one more thaw. This thaw revealed a 40-cent pan and kept increasing until it ran into hundreds of dollars to the pan; the claim yielded nearly half a million dollars in gold in the next six weeks.

The climate is the worst drawback to Alaska. At the most, the open season does not last over four months and during the remaining eight of the year the land is ice-locked so that transportation and communication by water are at a standstill; also all open surface mining; which practically makes one year's surface or placer mining in California equal to three years in Alaska. The drift mining carried on during the winter has become a permanent branch of the industry. The average depth of the ground in the Nome region where winter drifting is carried on successfully, is from 80 to 100 feet.

Notable among the rich strikes made this winter is that made on the Cyrus Noble claim, situated above the head of Bourbon creek, in the foothills about five miles north of Nome. The pay on this claim is found in an old beach deposit, which runs along the foot of the present hills; pans running as high as $500 have been taken from this claim. So far as the claim is exploited at the present time, it shows a paystreak about 40 ft. wide. This claim is destined to become one of the great producers of this section in the near future. Another rich and important strike has been made only a few days ago on No. 8 Cooper gulch. This claim is situated on the tundra just below the foothills where Cooper gulch empties into the tundra. It is apparently on the same old beach deposit as the Portland bench and Cyrus Noble. It is now predicted that it will prove the richest discovery ever made on the tundra. The future of the Seward peninsula as a quartz mining country of importance is encouraging. More promising quartz discoveries have been made in the past season than at any time in the history of the peninsula. Aside from the tin mines and free-milling gold ore, important discoveries have been made of lead (galena carrying silver) ores, telluride, cinnabar, platinum, manganese, talc and native metallic bismuth. The discovery of bismuth was made last summer by Louis Dahl, in the Sawtooth range, which heads the rivers flowing into Bering Sea on either side of Nome for a distance of 40 or 50 miles. The bismuth, which has rarely been found in this condition in nature, is in a metallic form, of a silvery gray color and lies in a matrix of bluish quartz, somewhat similar in form to cubic crystals of iron pyrite, such as are commonly found throughout Calaveras and Butte counties, California. Judging from the samples of the ore I have examined, it will go 25 to 30% bismuth. There has not been development work enough done yet on the ledge to prove how extensive the orebody is. The development work on other quartz lodes, however, has progressed far enough to show that at no distant date the familiar sound of the stamp-mill will be heard in many places within a day's journey of Nome.

DENVER, April 14.

The enterprise of the Yak Mining, Milling & Tunnel Company, is of great importance, not only to the Leadville district, but to the entire State; on account of the magnitude of the operations, the successful utilization of electric power and its close connection with the American Zinc Extraction Company. The Yak company is developing ground and opening up bodies of ore, from the portal of the tunnel throughout its territory, to the Ibex property, an extent of two miles, and laterally one-half mile on each side of the tunnel. The company generates electric power for its own use; its power-house is equipped with modern appliances affording the utmost elasticity, convenience and economy of operation. The electro-mining machinery consists of impact drills, diamond-core drills, pumps, mine-hoists, etc. The many applications of electric power, though more varied than those of other mines of the State, have not superseded the use of compressed air for particular operations. A prominent official of the company states that the electric-driven drills are not found to be as satisfactory as the air-actuated machines.

Though also treating other ores, the American Zinc Extraction Company's mill, with a daily capacity of 200 to 300 tons, is operated in close connection with the Yak property. In the mill there is conducted a special zinc-separation process, in which the International separator plays an important part. The whole problem of the Yak company is to mine cheaply and prepare for market large bodies of low grade ore. As a result of its operations to date, it is paying small dividends on its stock, with reasonable expectations of increasing them.

The Argo Mining Development, Transportation and Tunnel Company, owning the Newhouse Tunnel, in Clear Creek and Gilpin counties, has let an extension contract of 1000 ft. to Silas A. Knowles, formerly superintendent for the company. The bore is completed for a length of about three miles and the company is now considering extending it one and one-half miles further. J. J. May, recently superintendent of the tunnel, vacated that position to conduct operations on his own property in Mexico.

Louis Kannta, president of the Black Bear Mining Company of Telluride has contracted for a 10-stamp mill, which will be erected close to the Black Bear mine in Ingram Basin. The Wagner Bros. operating the Bradley mine near Telluride, have installed ten new stamps in the old Cimmaron mill, across the gulch from the Bradley, and expect to add 30 more stamps this season. In 1896 the operators of the Bradley-Pioneer Gold Mining Company stripped the ore in an adit drift for a distance of several hundred feet. Considerable money was raised in London for the operation and purchase of the Bradley and Pioneer properties, part of which was legitimately applied to the purpose intended and a larger part diverted, misapplied and squandered. A member of the directory not a party to the shady transactions, transmitted a detailed statement of the disposition made of the money sent from London to the agent at 10 Throgmorton Ave., London; naturally the remittances ceased, the options ran out and the property passed into other hands. The mine was thereafter worked at intervals without discovering ore, until last year, when the Wagners broke down the stripped ore, disclosing a continuous pay-streak two to four feet wide of an excellent milling grade. It is said the drift was run 400 to 500 ft. alongside the pay. The Bradley promises to become a heavy producer of lead, silver and gold ore. It is unfortunate that the Englishmen did not take legal measures against their representatives on this side and hold the property.

The Smuggler-Union mill at Pandora is dropping 120 stamps on ore produced by lessees.

Newspaper reports to the effect that the Camp Bird would rebuild its stamp mill in, and remove its plant to the town of Ouray, are denied by the management. The cyanide plant and other buildings, representing a large investment, are too valuable to abandon. The stamp-mill will be rebuilt on practically the same ground it formerly occupied and protective measures will be taken to prevent a repetition of the recent disaster.

Several successful runs have ben made at the Ross smelter, formerly the Kendrick smelter, at Silverton, by Mr. Hoyt, productive of a 55% copper matte. The smelter has been closed on account of the snow blockade making it impossible to get ore to it, but it will be started again as soon as ore can be delivered.

In a lawsuit brought by the Mine and Smelter Supply Company against John S. Carey for stock of the Wilfley Ore Concentrator Company of London, Judge Booth M. Malone on the 13th inst. rendered a decision in favor of Carey. Plaintiff's attorney stated to the Court that his client might move for an appeal, and the case was not dismissed.

Mr. Forrest D. Goody, who made a successful run of 2100 tons by cyanidation of the Golden Fleece (Hinsdale county) mill-tailing last season, will commence similar work again about June 1st.

Denver and Rio Grande Railway trains reached Silverton on the 14th inst. after a snow blockade lasting since March 18.

WASHINGTON, D. C., April 21.

During the coming summer the Government will extend its hydrographic investigations to Alaska, in order that data in regard to water supply, which is the important factor in the mining operations of this territory, may be available.

The United States Geological Survey since 1898 has devoted much time and energy to the study of the conditions which pertain to the production of gold in Alaska. These studies have included geological investigations, methods of mining, and topographic surveys; and the results, which have been published in the various reports of the Geological Survey, have been of great assistance, not only to those who are now working in Alaska, but to all interested in its development. The topographic surveys have yielded excellent reconnaissance maps of many of the developed portions of Alaska, and some detailed maps of the more important mining districts. The geological investigations have furnished many facts bearing on the distribution of gold in the various districts. The methods used in mining have been carefully studied and compared. Information in regard to general conditions, such as climate, transportation facilities, etc., has also been collected and published.

In 1905 four-fifths of the total gold output (about $15,000,000) of Alaska, was taken from placer deposits, for the development of which an ample supply of water is essential. This water supply is obtained from surface streams, and but little information is now available in regard to the flow of these streams or its distribution throughout the season. Such lack of information often causes financial failure in mining as well as other hydraulic works. The importance of such an investigation to a placer field is well illustrated by the conditions in the Klondike where, the richest placers having been exhausted, the gold remaining in the gravel can only be reclaimed by the installation of expensive hydraulic plants. This installation will, however, have to be delayed because there is little accurate data available regarding the run-off of the streams, and hence the advancement of the mining industry of the district will be retarded until the hydrographic surveys are completed.

For a number of years the Geological Survey has carried on systematic study of the water supply in the United States as one of the great resources of the country, in order that data might be available for engineers and others who contemplate making hydraulic developments. These data are now available for all the more important streams in the United States, and are extensively used in problems of power development, city water supply, irrigation and manufacturing.

The hydrographic work in Alaska during this season will be confined to the Nome region in the southern part of the Seward Peninsula, where a party in charge of Mr. John C. Hoyt will spend the entire season collecting information in regard to the more important streams which are now being utilized in mining operations. Later the work will be extended

streams in other portions of Alaska. It is expected, however, that the data collected during the coming season will be of such general nature that estimates can be made by comparison of the water supply in other sections than that in which the operations are carried on.

DENVER, April 23.

Colorado has often been blessed by the fact that her mines are difficult to exhaust. This is not due entirely to the persistentence of the orebodies. It is due almost as much to the fact that while persistent, they are often not continuous, but inclined to be erratic. If the ore-shoots were continuous like coal seams for instance, Colorado would probably have been worked out long ago, for it is not part of the American disposition to tarry long over converting developed ore into bank account. At the present time Leadville and Cripple Creek are demonstrating the seeming inexhaustibility of Colorado's resources. Leadville was not only given up for dead by the doctors, but was spoken of by her friends as one of the noble departed ones. Her funeral sermon had been delivered and her epitaph written, "Here lieth Colorado's greatest mining camp." Now Leadville arises from her casket, striding forth a juvenated giant. The recent discoveries in the Mammoth, the Yak tunnel, and the Bessie Wilgus have proved that there is a mineralized area surrounding Leadville that was little dreamed of, even in its palmiest days. There is one orebody exposed in the Yax tunnel which is 50 ft. thick, 125 ft. wide and 275 ft. long and of better than average grade. These figures do not define the limits, but represent development—up to those limits. The discovery in the Mammoth is stupendous, but development has not progressed sufficiently to demonstrate the extent of the orebody. This discovery proves, however, that the typical Leadville orebodies underlie Big Evans Flats, and this district alone is larger than the famous old down-town section.

The discovery in the Bessie Wilgus is of the high-grade, silver-chloride character of stuff. The orebody is large as well as rich. These three new districts indicate that the mineralized area of Leadville is shaped like a frying-pan, in which old Leadville was confined to the handle. The Little Johnny seems to feel the general re-awakening and is threatening to beat all past records in the way of tonnage.

The new discoveries, strange to say, all lie between the old camp and the Mosquito range. Down in the other direction they are going after the deep leads that are believed to lie there. The mining world has been prepared to hear of rich strikes in that locality for some time, but was surprised to hear such good reports from the other side of the camp.

Cripple Creek is likewise disproving the theory that her ore-shoots did not go down. Cripple Creek's ore-shoots are lenticular in form, and there are about as many of them at one level as on another.

D. W. Brunton's report advocating the driving of the deep drainage tunnel assures us that, as far as engineering skill can determine, the Cripple Creek orebodies are still abundant and valuable in depth.

With both Leadville and Cripple Creek getting their second wind Colorado can afford to take an optimistic view of things in general and of her mining possibilities in particular.

The snowslides in the San Juan are already things of the past and now is the time to expect new discoveries in that quarter. It may not be generally known that many of the good mines of the San Juan were laid bare by snowslides. Every spring the prospectors eagerly watch the retreating snows wherever a snowslide has scught a new path, to see what may have been uncovered by the slide. This year hundreds of hillsides have been scraped bare of everything but solid rock that were never exposed before, and the prospectors are apt to reap a rich reward.

DENVER, April 24.

The death of Edward G. Stoiber has cast a gloom over mining circles in Denver. He died, after a short attack of typhoid fever, on Saturday, April 21, 1906, at Paris, France. About two months ago Mr. Stoiber was around Colorado renewing acquaintance with his old friends, of which he had a large number. Mr. Stoiber was modest, retiring and scientific. He seemed almost out of place in the rough and tumble struggle of a mining camp. Yet he succeeded where others had failed. He built up a splendid enterprise based on the Silver Lake mines near Silverton, Colorado. Although not at all gregarious, he endeared himself firmly to a large circle of friends, all of whom feel that one of the oases on this world's desert has gone dry with his death. He is survived by his wife, his household not being blessed with children. Mrs. Stoiber was half partner with her husband in his mining enterprises and is one of the notable women of Colorado. She is renowned for her indomitable spirit and her generous hospitality.

The contract was let for a 50-ton concentrating mill at Silver Plume on April 17. This event is of special interest because it is the fourth mill to be erected in Silver Plume within the last year. It is truly wonderful the way these old camps revive as metallurgical processes improve and mining costs become lessened. Three years ago I rode through Silver Plume and a deader looking place I have seldom seen. Now all is bustle and energy. The stores are being re-painted and the sidewalks renewed. Prosperity has come again, not so much through the work done underground at Silver Plume, as through the patient toil of the inventors and metallurgists in Denver where improved processes for treating complex ores have been worked out and better mining machinery designed and made. Along the same general line of activity may be mentioned the recently ordered mill for the Black Bear Mining Company of Telluride. The Black Bear is no new discovery. It has been known and worked more or less for a long time, but the recent improvements in mining machinery make the prospective profits much greater than they would have been a few years ago.

The rise in the price of silver, lead and zinc also has its beneficial effect on the mining industry of the State, and as the winter snows go off, it is evident that an unusually large number of "outfits" are starting forth to prospect and do development work.

SALT LAKE CITY, April 23.

The annual meeting of shareholders of the Star Consolidated Mining Co., operating in the Tintic district, resulted in the election of H. G. McMillan, C. M. Freed, J. P. Turner, F. D. Kimball as directors. About 3,000 ft. of development was performed during the year and Superintendent Turner, in his report, gave assurance that conditions were more favorable than a year ago; that there are from 20,000 to 30,000 tons of mill ore available which will net anywhere from $5 to $7, while there is a large tonnage of silicious ore which the smelters will need later. The receipts of the year amounted to $28,984.72, which includes $23,602.12 received from two assessments. The disbursements exceeded receipts by $174.70. The present indebtedness is $26,740.61.

The ore-shoot opened on the 1500 level of the Daly-Judge mine at Park City, is entirely in virgin ground, there being no levels above or below it, and it has been found to be 270 ft. long. The shoot is believed to be as large as any ever found in the Daly-West, adjoining, and carries principally lead and silver. The company began the year with a bonded indebtedness of $209,000, and other obligations to the amount of $30,000. After a vigorous development campaign of 18 months, production was resumed Jan. 1, last. Since then, $97,000 worth of bonds have been paid, also the $30,000 item, leaving $112,000 of the bonded debt to be met. But the company has been clearing about $50,000 monthly, and has not crowded extraction. Stoping will begin on the 1,500 at once, which means an increase in output as well as in earnings. An official says the company will be entirely out of debt in June and have a surplus.

The Bingham Central Mining Co., at Bingham, has had placed to its credit the proceeds from the sale of the $200,000 worth of bonds recently placed, on which it will draw for the further development and equipment of its mines. The property is situated in the upper part of the camp, near the Boston Consolidated, and Utah Consolidated mines.

The management of the West Quincy mine at Park City will shortly undertake the further development of its ground by the use of core drills, to be operated from the 440 level. The lower workings of the mine are filled with water. G. B. Turner, manager, says the water level is considerably lower than a few months ago, and he believes development in adjoining mines has afforded an outlet, which means that in a little time the ground will probably be entirely drained.

Tony Jacobson of Salt Lake City, president of the recently organized Columbus Extension Co. at Alta, has placed an order for power equipment, and as soon as it is installed will begin driving a tunnel to tap the ore bodies. The proposed adit will be nearly a mile in length when finished.

The tunnel being driven on the Indian Queen mine in Beaver county is in 500 feet, and the new shaft at the Tetro mine in the Tintic district is nearing 400 ft. depth.

The initial shipment from the Little Bell mine, at Park City, amounting to 205,450 lbs., was sold on controls showing 69 oz. silver, 22% lead and 2.3% copper.

At the Waterbury leaching plant, built at Newhouse to leach the carbonate copper ore of the Cactus mine, the tests are now in progress.

The Utah Copper Co. has begun the excavations for the second section of the large concentrator, now in course of construction at Garfield. The foundations for this unit are to be completed by August 1.

R. H. Channing, Jr., manager of the Utah Consolidated Mining Co., has gone to the executive offices of the company in New York, and there is a well-founded belief that while there plans for future smelter enlargements will be discussed and which are fully warranted by present mine conditions. This statement is borne out by Channing's recent report to shareholders in which he stated that during 1905, 12,444 ft. development work was performed and that 4,586 of this was in ore, the result of which was to put in sight nearly 300,000 tons of ore, all from orebodies, the existence of which was not previously known, and that in at least two of these the limits have not been determined. He aims to keep two years ahead and deems that is all that is necessary.

Trade Treatises.

The Taylor Engineering Co. of 114 Liberty St., New York, has issued Bulletin 50, descriptive of their furnaces and smelting accessories. It contains a brief chapter on smelting and smelters and illustrates with excellent half-tones their several types of furnaces; forehearths, both movable and stationary; converters; hot-blast stoves and blowing engines.

Commercial Paragraphs.

The following orders are reported by the Lima Locomotive & Machine Company during the past week: New Orleans, 20-ton; San Francisco, Cal., 55-ton; Mobile, Ala., 65-ton; Shabuta, Miss., 28-ton; Shivers, Miss., 20-ton; Blind River, Ont., 28-ton.

The Pelton Water Wheel Co., San Francisco, state they are filling orders as usual from their eastern works and are in a position to furnish estimates on water wheels, sheet-steel riveted and lap-welded pipe, and complete hydraulic plants. Their new factory at 19th and Harrison St., San Francisco, was not injured by the recent fire and will be rushed to completion. As soon as this plant is finished the company will make shipments direct from the new plant.

Herman Unzicker, formerly with the old firm of Fraser & Chalmers and later with the Allis-Chalmers Co. is now associated with Chalmers & Williams, Railway Exchange, Chicago. Mr. Unzicker will be in the sales department and cover the territory west of Chicago.

The National Carbon Company, Cleveland, Ohio, are installing in their works at Clarksburg, W. Va., a 600 brake H. P. Koerting gas engine. supplied by the De La Vergne Machine Company of New York.

G. Frank Schwep has been at the head of the purchasing department of the Ingersoll-Sergeant Drill Company for the past thirteen years and was located at the shops at Easton, Pa., and Phillipsburg, R. I.

EDITORIAL.

THE RECENT OCCURRENCE shook a lot of the smallness out of humanity and made it big in generosity and in courage. It is curious how the old spirit of the pioneer days has descended on men who never expected to face the simple realities of life, as their fathers knew them in 1849. The spirit of the Argonauts has been transmitted and the people of San Francisco—nay, the people of California—are as full of life and hope in the rebuilding of their great City as were those who reclaimed the sand dunes, filled the marshes and leveled the hillslopes on which San Francisco was erected forty years ago. We used to date the beginning of the State from the rush of 1849, henceforth we shall speak of the new awakening that followed the event of 1906.

IT RECALLED old times in Colorado to see a train of supplies from that State arriving at Berkeley, in aid of those who suffered by the San Francisco conflagration. But when we saw two cars labeled from Denver and another from Breckenridge, it seemed like a message from personal friends. Good little Breckenridge, famous the world over for the wonderful specimens of native gold, has proved the possession of a warm heart and a helping hand—something that gold does not buy and more exquisite than the most gorgeous of the crystalline aggregates that come from the mines of Farncomb hill. Indeed, one of the great compensations of a disaster that appeals to the imagination and sensibilities of mankind, is the stimulation of sympathy and the emphasis placed upon the essential kinship of the race. We do not doubt as to who is the most enriched, the sufferer who receives aid in time of trouble or the man whose whole nature is uplifted by a noble impulse.

THE CONFLAGRATION was so complete that many former buildings are indicated by a mere remnant of rubble. Whole blocks 300 by 500 feet were swept by the flames in three-quarters of an hour. The conflagration was of such a magnitude that the intensity of heat was terrific. Girders two feet wide can be seen tortured into strange curves. A few houses survive on the top of Russian hill and Telegraph hill; the Fairmont stands like a great acropolis overlooking the ruins of an ancient city. The few surviving sky scrapers look gaunt and ragged. Distance is killed by absence of landmarks and the erasure of high walls; the City appears to have shrivelled, it seems no distance between points formerly too far to walk. Squares we thought commodious air spaces have dwindled to insignificant enclosures. At a distance the streets meet the sky-line with a slight indent, the roadways make gray bands among rectangles of dark wreckage; a few chimneys stand tottering drearily above the ashes of vanished homes.

After the Disaster.

San Francisco is known to mining men the world over as a delightful rendezvous; from the Nevada deserts, from the Arizona border, from the Mexican ports, from the hills of California, from Australia and the Orient, the seekers after mineral wealth come to the City by the Golden Gate, and there enjoy the rest, the pleasure and the associations that compensate for the weariness of travel and the stress of professional labor. To them it will be a matter of interest to learn how the City looks after having passed through earthquake and fire.

As you cross the Bay from Oakland or Berkeley, the City looks scarcely different; such prominent landmarks as the Ferry tower, the Call building, the Fairmont hotel and other familiar structures are visible, but as you look closer you note the absence of tone; it is all dull. The glory of life has gone, it is a ruin that you see. As the ferry passes Goat island and begins to approach the landing, the destruction becomes apparent. The Ferry building is there with bowed lines that tell of structural injury and the tower appears out of plumb. The flagstaff is bent and the clock still points to the moment when it was shaken to a full stop. It says 5:16, but then the ferry clock never was a reliable time-piece and the quake might well have discovered it one or two minutes fast. The scaffolding around the tower indicates the work of repair; it is doubtful whether it will not be necessary to rebuild at a later date. On emerging from the Ferry building, one was accustomed to the full-toned voice of a big town, intensified by traffic over the cobbles of Market street and the confused shouts of hotel runners, the strident cries of newsboys and the clanging of car bells. All these are silent; the noises are those of a village; the wagons, express carts, and men on horseback partially screen a ghastly background. Heaps of brick and tottering portions of walls stretch far and wide in pathetic desolation; and far above them, like the surviving giants of a mighty forest that has been stricken by fire, there looms the stately skeleton of the Call building and other 'sky-scrapers'—a popular term that has the sound of a sad irony. Most of the streets are blocked with a disorderly heap of brick and iron, although one or two main arteries have already been partially cleared so that it is easy to pass through the ruins.

The effects of the earthquake have been partially obliterated by the conflagration, for the disturbed surface is covered with rubbish and the buildings that collapsed were among the first to burn, with a fierceness of combustion that is readily appreciated when the cause is understood. The shock of the earth tremble broke the gas mains and their inflammable content was immediately ignited by the sparks from severed electric wires. Thus does the complexity of civilization add new terrors and until the aids to material comfort are safeguarded by the inventive genius that created them, man would better live as his ancestors did. Those who live in tents and know no illuminant save the camp fire, would have remembered an earthquake such as that of April 18 only as a dizzy moment when trees rocked and the tent-poles shook. But we live no longer as nomads; we raise structures that go far above the trembling soil. On Valencia street, between 18th and 19th streets, there was a hotel, a large wooden structure. The ground on which it stood sank the height of one story and the building collapsed, killing several people. The site of it is not recognizable, for the fire stripped it clean; but the adjoining tract affords interesting evidence. Valencia street has sunk 8 to 10 feet and looking east over the charred remains of two intervening blocks, one sees another frame building that has lurched like a drunken man. This particular part of the City—on the south side—stands on an old creek-bed that has been filled. Down 18th street also, from Valencia to Howard, the ground has sunk on the north side along the center of the cobble-paved roadway and there is a crack 12 to 15 inches wide along the line of rupture. Neighboring houses show the effects of disturbance. Evidence of a similar kind is obtainable elsewhere in this vicinity and it is noteworthy that the belt of deranged buildings and dislocated roadways follows exactly the line of the filling over the old creek. In another locality, at the southwest corner of the new Post Office, the street and sidewalk have sunk five feet from the building, which stands solid and safe on

its own properly constructed foundations. At the corner of Steuart and Market streets, the roadway has dropped bodily fully five feet while the sidewalk stands at its former level; for the sidewalk and adjoining buildings were built on piles, and the roadway was not. On Van Ness avenue, between Green and Vallejo streets, the asphalt is buckled and cracked right across—east and west— while the flagstones on Green street have slid northward 15 inches over the edge of the curb. Finally, in front of the Ferry building, the ground has sunk three feet and the asphalt is cracked along a line running nearly north and south. These few facts were collected in the course of a four hours' walk and they point to one conclusion, which is confirmed by other evidence not necessary to detail. The site of San Francisco included a large area of made land, reaching from about Montgomery street to the Bay; the city limits also included several swamps and creek-beds, all of which in process of time became filled with the material excavated from the higher ground. These weak spots were largely forgotten by the residents and disregarded by builders, but they are now rendered prominent and their memory is revived, because at such places the lack of special care in construction has caused buildings to collapse. There was no regional subsidence in San Francisco, as far as can be ascertained.

The fire has obliterated much valuable evidence in regard to structural defects in buildings, but enough survives to tell a perfectly plain story. No scientifically designed and honestly built structure was injured by the earthquake; many well designed and dishonestly built structures suffered and many more that were both faulty in design and wretchedly built did collapse. The earthquake is a master inspector; no political pull, no sham masonry, no certificate of an incompetent board of works will prevent the ruthless exposure of bad work when Nature sets about to make a crucial test. And there was lots of dishonest and foolish construction in San Francisco, as there is in every rapidly built city anywhere on this continent or even on some of the others. Of all the architectural frauds in San Francisco, the City Hall stood, as it fell, in a class by itself. During the long term of years occupied in the building of it, the City Hall has enriched a succession of contractors and it was notorious for bad work. It is a sorry sight; the big dome has been stripped of its stone, leaving a bird-cage of steel trusses, the roof has fallen and the walls have crumbled; it looks like the disheveled remains of a doll's house, shaken to pieces. The building that housed the City's administration and should have been an example of architectural skill and artistic taste, has collapsed miserably, because every stone of it was laid in putrid politics; it is a disgraceful ruin, the great dome is stripped of its veneer of stone as thoroughly as the iniquity of the builders stands plain to every beholder. Let the City Hall stay as it is for twenty years, a monument to greed and a warning to dishonest builders—"Lest we forget"; for in the rush and activity of a resourceful community, we are only too likely to discard the lessons of the past, and when the first hurt of the recent blow has healed we shall be in such a hurry as to become again complacent to poor construction and the condoning of dishonest contractors.

On the other hand, the structures erected by the Federal Government have proved their stability and the fact that they were in some cases provided with an artesian water supply also indicates a rare good sense. To these factors the community owes the inestimable good fortune of still possessing a post-office and a mint that can play their necessary part in clearing the confusion of business caused by the recent catastrophe. But there are many other buildings that exemplify the results of good work well done. Most of the tall office buildings, constructed of steel and erected on proper foundations of steel and concrete, have stood the test and will become the nucleus of a new hive of industrial life. Among these, the big Call building stands pre-eminent. To most men it had often suggested the question of safety during an earthquake and of all the proud sky-scrapers it seemed the one that most wantonly braved such a peril. It is sixteen stories high and is surmounted by a big dome that contains three floors more. With a base 75 feet square, it is 300 feet high. Observers have spoken of telegraph poles that swayed wildly and that bent like a reed in the wind; what must have been the swing at the top of that great tower of steel and stone? Nevertheless, there it stands, unscathed, without a visible crack, devastated by the flame but triumphant over the tremblor. Let us feel ashamed of the sordid dishonesty of the men who built the City Hall, but we can well afford to be proud of the scientific knowledge and the honest handiwork that dared—and yet not unwisely—to erect that splendid structure, which looks down today over a world of ruin and inspires the people of San Francisco to the proper recognition of the value of good building construction. Look at this picture and on that! Look down on the ruins of the City Hall and look up to the Call building, standing like a monolith. Now let the new City be built with similar skill and with a like honesty of construction, so that San Francisco shall be the best example of modern methods, a glorious monument to the science of the engineer and the genius of the artist, the home of the Argonauts and the pride of the Pacific Coast.

The Misuse of Explosives.

One feature of the conflagration will interest miners and if they had observed it, we believe that they would agree with us in thorough-going condemnation. We refer to the misuse of explosives in blasting buildings. If it had been planned systematically and carried out properly, much of the City could have been saved, but it was far otherwise. The use of high-grade explosives by people ignorant of their strength and proper application, was instrumental in destroying a vast amount of property without the result desired, and in many cases it actually spread the conflagration. The work was done by Dick, Tom and Harry, until the very end of the operations when the naval officers from Mare Island took a hand and directed affairs in a scientific manner. Before that the police, the militia, and volunteer firemen used a box of dynamite where a pound would have sufficed, they blasted on the wrong side of walls and did such foolish things as placing a keg of black powder in the center of wooden buildings, with the result that they set them afire instead of bringing them to the ground. Spectators could see that the explosion threw up a lot of dust, to be followed forthwith by flame. They dynamited buildings already on fire and simply made an avenue for the spread of the conflagration instead of creating an obstacle to its advance. Under such conditions, the explosion scattered brands right and left On Van Ness avenue there was a deplorable amount of damage needlessly done to handsome frame buildings by the use of black powder, that utterly failed of its purpose. It was the veering of the wind and the persistent application of blankets and sacking soaked in the waters found in kitchen boilers by heroic volunteer firemen that eventually saved the Western Addition. However excusable the poor judgment shown during a time of great strain and excitement, there was nothing to palliate the stupidity exhibited in the attempts to blast dangerous walls when the conflagration was at an end. While such operations were being carried out on Market street, there was danger to anyone within three or four blocks; 150 pounds of dynamite were used where as much could have been accomplished by five or six pounds properly applied. Boxes containing 50 pounds apiece were placed against a wall with a light cover of sand and exploded with needless waste and danger. A drill-hole or two properly pointed would have thrown the wall in any direction desired. There was plenty of time to do it properly. A glaring example of such blunders occurred at the Post Office several days after the conflagration; this building was hardly injured by either fire or earthquake, but when the amateur blasters came on the scene, they nearly wrecked it in their childish efforts to pull down the walls of the neighboring Odd Fellows building. It is officially stated that the foundations of the Post-Office were hurt by the blasting and the south side was so wrecked that the damage is estimated at $100,000. It might be supposed that with so many experienced mining men in the community, it would have been possible to get their help in work which they understood and we can state that several of our friends did volunteer to give suggestions and to proffer systematic aid, but in vain. It is difficult to persuade a man that he does not understand what he is doing. San Francisco has reason bitterly to rue the misuse of the explosives that properly employed have proved so powerful an aid to the advancement of mining.

The Effect in Mines
